Note that the completion routine next to the driver name is set on that stack location, and it was set by the driver in the line below. In the preceding example, **Ntfs!NtfsMasterIrpSyncCompletionRoutine** was set by **\FileSystem\Ntfs**. The **Completion-Context** entry above **Ntfs!NtfsMasterIrpSyncCompletionRoutine**, **847eede0-829e2ba8**, indicates the address of the completion routine, as well as the context that will be passed to **Ntfs!NtfsMasterIrpSyncCompletionRoutine**. From this we can see that the address of **Ntfs!NtfsMasterIrpSyncCompletionRoutine** is **847eede0**, and the context that will be passed to this routine when it is called is **829e2ba8**.

IRP major function codes

The following information is included to help you interpret the output from this extension command.

The IRP major function codes are as follows:

MAJOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MJ_CREATE	0x00
IRP_MJ_CREATE_NAMED_PIPE	0x01
IRP_MJ_CLOSE	0x02
IRP_MJ_READ	0x03
IRP_MJ_WRITE	0x04

MAJOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MJ_QUERY_INFORMATION	0x05
IRP_MJ_SET_INFORMATION	0x06
IRP_MJ_QUERY_EA	0x07
IRP_MJ_SET_EA	0x08
IRP_MJ_FLUSH_BUFFERS	0x09
IRP_MJ_QUERY_VOLUME_INFORMATION	0x0A
IRP_MJ_SET_VOLUME_INFORMATION	0x0B
IRP_MJ_DIRECTORY_CONTROL	0x0C
IRP_MJ_FILE_SYSTEM_CONTROL	0x0D
IRP_MJ_DEVICE_CONTROL	0x0E
IRP_MJ_INTERNAL_DEVICE_CONTROL IRP_MJ_SCSI	0x0F
IRP_MJ_SHUTDOWN	0x10
IRP_MJ_LOCK_CONTROL	0x11
IRP_MJ_CLEANUP	0x12
IRP_MJ_CREATE_MAILSLOT	0x13
IRP_MJ_QUERY_SECURITY	0x14
IRP_MJ_SET_SECURITY	0x15
IRP_MJ_POWER	0x16
IRP_MJ_SYSTEM_CONTROL	0x17

MAJOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MJ_DEVICE_CHANGE	0x18
IRP_MJ_QUERY_QUOTA	0x19
IRP_MJ_SET_QUOTA	0x1A
IRP_MJ_PNP IRP_MJ_MAXIMUM_FUNCTION	0x1B

The Plug and Play minor function codes are as follows:

MINOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MN_START_DEVICE	0x00
IRP_MN_QUERY_REMOVE_DEVICE	0x01
IRP_MN_REMOVE_DEVICE	0x02
IRP_MN_CANCEL_REMOVE_DEVICE	0x03
IRP_MN_STOP_DEVICE	0x04
IRP_MN_QUERY_STOP_DEVICE	0x05
IRP_MN_CANCEL_STOP_DEVICE	0x06
IRP_MN_QUERY_DEVICE_RELATIONS	0x07
IRP_MN_QUERY_INTERFACE	0x08
IRP_MN_QUERY_CAPABILITIES	0x09
IRP_MN_QUERY_RESOURCES	0x0A
IRP_MN_QUERY_RESOURCE_REQUIREMENTS	0x0B
IRP_MN_QUERY_DEVICE_TEXT	0x0C

MINOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MN_FILTER_RESOURCE_REQUIREMENTS	0x0D
IRP_MN_READ_CONFIG	0x0F
IRP_MN_WRITE_CONFIG	0x10
IRP_MN_EJECT	0x11
IRP_MN_SET_LOCK	0x12
IRP_MN_QUERY_ID	0x13
IRP_MN_QUERY_PNP_DEVICE_STATE	0x14
IRP_MN_QUERY_BUS_INFORMATION	0x15
IRP_MN_DEVICE_USAGE_NOTIFICATION	0x16
IRP_MN_SURPRISE_REMOVAL	0x17
IRP_MN_QUERY_LEGACY_BUS_INFORMATION	0x18

The WMI minor function codes are as follows:

MINOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MN_QUERY_ALL_DATA	0x00
IRP_MN_QUERY_SINGLE_INSTANCE	0x01
IRP_MN_CHANGE_SINGLE_INSTANCE	0x02
IRP_MN_CHANGE_SINGLE_ITEM	0x03
IRP_MN_ENABLE_EVENTS	0x04
IRP_MN_DISABLE_EVENTS	0x05

MINOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MN_ENABLE_COLLECTION	0x06
IRP_MN_DISABLE_COLLECTION	0x07
IRP_MN_REGINFO	0x08
IRP_MN_EXECUTE_METHOD	0x09

The power management minor function codes are as follows:

MINOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MN_WAIT_WAKE	0x00
IRP_MN_POWER_SEQUENCE	0x01
IRP_MN_SET_POWER	0x02
IRP_MN_QUERY_POWER	0x03

The SCSI minor function codes are as follows:

MINOR FUNCTION CODE	HEXADECIMAL CODE
IRP_MN_SCSI_CLASS	0x01

[IRP](#)

[!irpfind](#)

[!ioctldecode](#)

[Send comments about this topic to Microsoft](#)

!irpfind

5/31/2017 • 1 min to read • [Edit Online](#)

The **!irpfind** extension displays information about all I/O request packets (IRP) currently allocated in the target system, or about those IRPs matching the specified search criteria.

Syntax

```
!irpfind [-v][PoolType[RestartAddress[CriteriaData]]]
```

Parameters

-v

Displays verbose information.

PoolType

Specifies the type of pool to be searched. The following values are permitted:

0

Specifies nonpaged memory pool. This is the default.

1

Specifies paged memory pool.

2

Specifies the special pool.

4

Specifies the session pool.

RestartAddress

Specifies the hexadecimal address at which to begin the search. This is useful if the previous search was terminated prematurely. The default is zero.

Criteria

Specifies the criteria for the search. Only those IRPs that satisfy the given match will be displayed.

CRITERIA	MATCH
arg	Finds all IRPs with a stack location where one of the arguments equals <i>Data</i> .
device	Finds all IRPs with a stack location where DeviceObject equals <i>Data</i> .
fileobject	Finds all IRPs whose Irp.Tail.Overlay.OriginalFileObject equals <i>Data</i> .

CRITERIA	MATCH
mdlprocess	Finds all IRPs whose Irp.MdlAddress.Process equals <i>Data</i> .
thread	Finds all IRPs whose Irp.Tail.Overlay.Thread equals <i>Data</i> .
userevent	Finds all IRPs whose Irp.UserEvent equals <i>Data</i> .

Data

Specifies the data to be matched in the search.

DLL

Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about IRPs, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

This example finds the IRP in the nonpaged pool that is going to set user event FF9E4F48 upon completion:

```
kd> !irpfind 0 0 userevent ff9e4f48
```

The following example produces a full listing of all IRPs in the nonpaged pool:

```
kd> !irpfind
Searching NonPaged pool (8090c000 : 8131e000) for Tag: Irp
8097c008 Thread 8094d900 current stack belongs to \Driver\symc810
8097dec8 Thread 8094dda0 current stack belongs to \FileSystem\Ntfs
809861a8 Thread 8094dda0 current stack belongs to \Driver\symc810
809864e8 Thread 80951ba0 current stack belongs to \Driver\Mouclass
80986608 Thread 80951ba0 current stack belongs to \Driver\Kbdclass
80986728 Thread 8094dda0 current stack belongs to \Driver\symc810
```

[Send comments about this topic to Microsoft](#)

!irpzone

The **!irpzone** extension command is obsolete. Use **!irpfind** instead.

[Send comments about this topic to Microsoft](#)

title: irql extension command description: The irql extension displays the interrupt request level (IRQL) of a processor on the target computer before the debugger break. ms.assetid: 52dd3b9f-c03c-4b90-a01b-25289de67f5a keywords: ["IRQL (Interrupt Request Level)", "IRQL (Interrupt Request Level), See "Interrupt Request Level (IRQL)", "irql Windows Debugging"] ms.author: windowsdriverdev ms.date: 05/23/2017 ms.topic: article ms.prod: windows-hardware ms.technology: windows-devices topic_type:

- apiref api_name:
- irql api_type:

- NA

!irql

The **!irql** extension displays the interrupt request level (IRQL) of a processor on the target computer before the debugger break.

```
!irql [Processor]
```

Parameters

Processor

Specifies the processor. Enter the processor number. If this parameter is omitted, the debugger displays the IRQL of the current processor.

DLL

The **!irql** extension is only available in Windows Server 2003 and later versions of Windows.

Windows 2000	Unavailable
Windows XP	Unavailable
Windows Server 2003 and later	Kdexts.dll

Additional Information

For information about IRQLs, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

When the target computer breaks into the debugger, the IRQL changes, but the IRQL that was effective just before the debugger break is saved. The **!irql** extension displays the saved IRQL.

Similarly, when a bug check occurs and a crash dump file is created, the IRQL saved in the crash dump file is the

one immediately prior to the bug check, not the IRQL at which the **KeBugCheckEx** routine was executed.

In both cases, the current IRQL is raised to DISPATCH_LEVEL, except on x86 architectures. Thus, if more than one such event occurs, the IRQL displayed will also be DISPATCH_LEVEL, making it useless for debugging purposes.

The **!pcr** extension displays the current IRQL on all versions of Windows, but the current IRQL is usually not useful. The IRQL that existed just before the bug check or debugger connection is more interesting, and this is displayed only with **!irql**.

If you supply an invalid processor number, or there has been kernel corruption, the debugger displays a message "Cannot get PRCB address".

Here is an example of the output from this extension from a dual-processor x86 computer:

```
kd> !irql 0
Debugger saved IRQL for processor 0x0 -- 28 (CLOCK2_LEVEL)

kd> !irql 1
Debugger saved IRQL for processor 0x1 -- 0 (LOW_LEVEL)
```

If the debugger is in verbose mode, a description of the IRQL itself is included. Here is an example from an Itanium processor:

```
kd> !irql
Debugger saved IRQL for processor 0x0 -- 12 (PC_LEVEL) [Performance counter level]
```

The meaning of the IRQL number often depends on the processor. Here is an example from an x64 processor. Note that the IRQL number is the same as in the previous example, but the IRQL meaning is different:

```
kd> !irql
Debugger saved IRQL for processor 0x0 -- 12 (SYNCH_LEVEL) [Synchronization level]
```

[Send comments about this topic to Microsoft](#)

!isainfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!isainfo** extension displays information about PNPISA cards or devices present in the system..

```
!isainfo [Card]
```

Parameters

Card

Specifies a PNPISA Card. If *Card* is 0 or omitted, all the devices and cards on the PNPISA (that is, the PC I/O) Bus are displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

Here is an example of the output from this extension:

```
0: kd> !isainfo
ISA PnP FDO @ 0x867b9938, DevExt @ 0x867b99f0, Bus # 0
Flags (0x80000000) DF_BUS

ISA PnP PDO @ 0x867B9818, DevExt @ 0x86595388
Flags (0x40000818) DF_ENUMERATED, DF_ACTIVATED,
DF_REQ_TRIMMED, DF_READ_DATA_PORT
```

[Send comments about this topic to Microsoft](#)

!isr

5/31/2017 • 1 min to read • [Edit Online](#)

The !isr extension displays the Itanium Interruption Status Register (ISR) at the specified address.

```
!isr Expression [DisplayLevel]
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Expression

Specifies the hexadecimal address of the ISR register to display. The expression `@isr` can also be used for this parameter. In that case, information about the current processor ISR register is displayed.

DisplayLevel

Can be any one of the following options:

0

Displays only the values of each ISR field. This is the default.

1

Displays detailed information about ISR fields that are not reserved or ignored.

2

Displays details about all ISR fields, including those that are ignored or reserved.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium target computer.

Remarks

Here are a couple of examples of output from this extension:

```
kd> !isr @isr
isr:ed ei so ni ir rs sp na r w x vector code
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

kd> !isr @isr 2

```

[Send comments about this topic to Microsoft](#)

!ivt

5/31/2017 • 1 min to read • [Edit Online](#)

The !ivt extension displays the Itanium interrupt vector table.

```
!ivt [-v] [-a] [Vector]
!ivt -?
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Vector

Specifies an interrupt vector table entry for the current processor. If *Vector* is omitted, the entire interrupt vector table for the current processor on the target computer is displayed. Interrupt vectors that have not been assigned are not displayed unless the **-a** option is specified.

-a

Displays all interrupt vectors, including those that are unassigned.

-v

Displays detailed output.

-?

Displays help for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium target computer.

Additional Information

For more information about how to display the interrupt dispatch tables on an x64 or x86 target computer, see [!idt](#).

Remarks

Here is an example of the output from this extension:

```
kd> !ivt
```

Dumping IA64 IVT:

!job

5/31/2017 • 1 min to read • [Edit Online](#)

The **!job** extension displays a job object.

```
!job [Process [Flags]]
```

Parameters

Process

Specifies the hexadecimal address of a process or a thread whose associated job object is to be examined. If this is omitted, or equal to -1 (in Windows 2000), or equal to zero (in Windows XP and later), the job associated with the current process is displayed.

Flags

Specifies what the display should contain. This can be a sum of any of the following bit values. The default is 0x1:

Bit 0 (0x1)

Causes the display to include job settings and statistics.

Bit 1 (0x2)

Causes the display to include a list of all processes in the job.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about job objects, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

Here is an example of the output from this extension:

```
kd> !process 52c

[Send comments about this topic to Microsoft](#)

!loadermemorylist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!loadermemorylist** extension displays the memory allocation list that the Windows boot loader passes to Windows.

```
!loadermemorylist ListHeadAddress
```

Parameters

ListHeadAddress

Specifies the address of a list header.

DLL

Windows 2000	Kdexts.dll
Windows XP	Kdexts.dll
Windows Server 2003	
Windows Vista and later	Kdexts.dll

Remarks

This extension is designed to be used at the beginning of the system boot process while Ntldr is running. It displays a memory allocation list that includes the start, end, and type of each page range.

You can stop execution at any point by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!lockedpages

5/31/2017 • 1 min to read • [Edit Online](#)

The **!lockedpages** extension displays driver-locked pages for a specified process.

Syntax

```
!lockedpages [Process]
```

Parameters

Process

Specifies a process. If *Process* is omitted, the current process is used.

DLL

Kdexts.dll

Remarks

You can stop execution at any point by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!locks (!kdext*.locks)

5/31/2017 • 2 min to read • [Edit Online](#)

The **!locks** extension in Kdextx86.dll and Kdexts.dll displays information about kernel ERESOURCE locks.

This extension command should not be confused with the **!ntsdexts.locks** extension command.

```
!locks [Options] [Address]
```

Parameters

Options

Specifies the amount of information to be displayed. Any combination of the following options can be used:

-v

Displays detailed information about each lock.

-p

Display all available information about the locks, including performance statistics.

-d

Display information about all locks. Otherwise, only locks with contention are displayed.)

Address

Specifies the hexadecimal address of the ERESOURCE lock to be displayed. If *Address* is 0 or omitted, information about all ERESOURCE locks in the system will be displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

The **!locks** extension displays all locks held on resources by threads. A lock can be shared or exclusive, which means no other threads can gain access to that resource. This information is useful when a deadlock occurs on a system. A deadlock is caused by one non-executing thread holding an exclusive lock on a resource that the executing thread needs.

You can usually pinpoint a deadlock in Microsoft Windows 2000 by finding one non-executing thread that holds an exclusive lock on a resource that is required by an executing thread. Most of the locks are shared.

Here is an example of the basic **!locks** output:

```

kd> !locks
**** DUMP OF ALL RESOURCE OBJECTS ****
KD: Scanning for held locks.....
```

Resource @ 0x80e97620 Shared 4 owning threads
Threads: ff688da0-01<*> ff687da0-01<*> ff686da0-01<*> ff685da0-01<*>
KD: Scanning for held locks.....

Resource @ 0x80e23f38 Shared 1 owning threads
Threads: 80ed0023-01<*> *** Actual Thread 80ed0020
KD: Scanning for held locks.

Resource @ 0x80d8b0b0 Shared 1 owning threads
Threads: 80ed0023-01<*> *** Actual Thread 80ed0020
2263 total locks, 3 locks currently held

Note that the address for each thread displayed is followed by its thread count (for example, "-01"). If a thread is followed by "<*>", that thread is one of the owners of the lock. In some instances, the initial thread address contains an offset. In that case, the actual thread address is displayed as well.

If you want to find more information about one of these resource objects, use the address that follows "Resource @" as an argument for future commands. To investigate the second resource shown in the preceding example, you could use **dt ERESOURCE 80d8b0b0** or **!thread 80ed0020**. Or you could use the **!locks** extension again with the **-v** option:

```

kd> !locks -v 80d8b0b0

Resource @ 0x80d8b0b0 Shared 1 owning threads
Threads: 80ed0023-01<*> *** Actual Thread 80ed0020

!logonsession

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logonsession** extension displays information about a specified logon session.

Free Build Syntax

```
!logonsession LUID
```

Checked Build Syntax

```
!logonsession LUID [InfoLevel]
```

Parameters

LUID

Specifies the locally unique identifier (LUID) of a logon session to display. If *LUID* is 0, information about all logon sessions is displayed.

To display information about the system session and all system tokens in a checked build, enter **!logonsession 3e7 1.**

InfoLevel

(Checked Build Only) Specifies how much token information is displayed. The *InfoLevel* parameter can take values from 0 to 4, with 0 representing the least information and 4 representing the most information.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about logon sessions, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Here is an example of the output from this extension on a free build:

```
kd> !logonsession 0

Dumping all logon sessions.

** Session 0 = 0x0

!lookaside

5/31/2017 • 1 min to read • [Edit Online](#)

The **!lookaside** extension displays information about look-aside lists, resets the counters of look-aside lists, or modifies the depth of a look-aside list.

```
!lookaside [Address [Options [Depth]]]
!lookaside [-all]
!lookaside 0 [-all]
```

Parameters

Address

Specifies the hexadecimal address of a look-aside list to be displayed or modified.

If *Address* is omitted (or 0) and the **-all** option is not specified, a set of well-known, standard system look-aside lists is displayed. The set of lists is not exhaustive; that is, it does not include all system look-aside lists. Also, the set does not include custom look-aside lists that were created by calls to [ExInitializePagedLookasideList](#) or [ExInitializeNPagedLookasideList](#).

If *Address* is omitted (or 0) and the **-all** option is specified, all look-aside lists are displayed.

Options

Controls what operation will be taken. The following possible *Options* are supported. The default is zero:

0

Displays information about the specified look-aside list or lists.

1

Resets the counters of the specified look-aside list.

2

Modifies the depth of the specified look-aside list. This option can only be used if *Address* is nonzero.

Depth

Specifies the new maximum depth of the specified look-aside list. This parameter is permitted only if *Address* is nonzero and *Options* is equal to 2.

Additional Information

For information about look-aside lists, see the [Windows Driver Kit \(WDK\) documentation](#) and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Look-aside lists are multiprocessor-safe mechanisms for managing pools of fixed-size entries from either paged or nonpaged memory.

Look-aside lists are efficient, because the routines do not use spin locks on most platforms.

Note that if the current depth of a look-aside list exceeds the maximum depth of that list, then freeing a structure associated with that list will result in freeing it into pool memory, rather than list memory.

Here is an example of the output from this extension:

```
!lookaside 0xfffff88001294f80

Lookaside "" @ 0xfffff88001294f80 Tag(hex): 0x7366744e "Ntfs"
  Type      =      0011 PagedPool RaiseIfAllocationFailure
  Current Depth =      0 Max Depth =      4
  Size      =      496 Max Alloc =     1984
  AllocateMisses =      8 FreeMisses =      0
  TotalAllocates = 272492 TotalFrees = 272488
  Hit Rate    =    99% Hit Rate =    100%
```

Requirements

DLL	Kdexts.dll
-----	------------

[Send comments about this topic to Microsoft](#)

!lpc

5/31/2017 • 5 min to read • [Edit Online](#)

Important

This extension is not supported in Windows Vista and later versions of Windows. Lpc is now emulated in alpc, use the !alpc extension instead.

The **!lpc** extension displays information about all local procedure call (LPC) ports and messages in the target system.

Syntax in Windows 2000

```
!lpc message MessageID
!lpc port Port
!lpc scan Port
!lpc thread Thread
!lpc
```

Syntax in Windows Server 2003 and Windows XP

```
!lpc message MessageID
!lpc port Port
!lpc scan Port
!lpc thread Thread
!lpc PoolSearch
!lpc
```

Parameters

message

(Windows Server 2003, Windows XP, and Windows 2000 only) Displays information about a message, such as the server port that contains the message in the queue, and the thread waiting for this message, if any.

MessageID

(Windows Server 2003, Windows XP, and Windows 2000 only) Specifies the message ID of the message to be displayed. If the value of this parameter is 0 or this parameter is omitted, the **!lpc message** command displays a summary list of messages. (In Windows 2000 with Service Pack 1 (SP1), the summary includes all messages in the LPC zone. In Windows 2000 with Service Pack 2 (SP2), Windows XP, and later versions of Windows, the summary includes all messages in the kernel pool. Paged-out messages are not included.)

port

(Windows Server 2003, Windows XP, and Windows 2000 only) Displays port information, such as the name of the port, its semaphore state, messages in its queues, threads in its rundown queue, its handle count, its references, and related ports.

scan

(Windows Server 2003, Windows XP, and Windows 2000 only) Displays summary information about the specified port and about all ports that are connected to it.

Port

(Windows Server 2003, Windows XP, and Windows 2000 only) Specifies the hexadecimal address of the port to be displayed. If the **!lpc port** command is used, and *Port* is 0 or is omitted, a summary list of all LPC ports is displayed.

If the **!Ipc scan** command is used, *Port* must specify the address of an actual port.

thread

(Windows Server 2003, Windows XP, and Windows 2000 only) Displays port information for all ports that contain the specified thread in their rundown port queues.

Thread

(Windows Server 2003, Windows XP, and Windows 2000 only) Specifies the hexadecimal address of the thread. If this is 0 or omitted, the **!Ipc thread** command displays a summary list of all threads that are performing any LPC operations.

PoolSearch

(Windows Server 2003 and Windows XP only) Determines whether the **!Ipc message** command searches for messages in the kernel pool. Each time **!Ipc PoolSearch** is used, this setting toggles on or off (the initial setting is to not search the kernel pool). This only affects **!Ipc message** commands that specify a nonzero value for *MessageID*.

DLL

Windows 2000	Kdextx86.dll
Windows XP	Kdexts.dll
Windows Server 2003	

Additional Information

For information about LPCs, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

This extension is not supported in Windows Vista and later versions of Windows.

In Windows Server 2003, Windows XP, and Windows 2000, using **!Ipc** with no arguments displays help for this extension in the Debugger Command window.

If you have a thread that is marked as waiting for a reply to a message, use the **!Ipc message** command with the ID of the delayed message. This command displays the specified message, the port that contains it, and all related threads.

If the message is not found and there were no read errors (such as "Unable to access zone segment"), the server received the message.

In this case, the server port can usually be found by using the **!Ipc thread** command. Threads that are waiting for replies are linked into a server communication queue. This command will display all ports that contain the specified thread. After you know the port address, use the **!Ipc port** command. More specific information about each thread can then be obtained by using the **!Ipc thread** command with the address of each thread.

Here are several examples of the output from this extension from a Windows XP system:

In this example, all port LPC ports are displayed.

```
kd> !lpc port
Scanning 225 objects
  1 Port: 0xe1405650 Connection: 0xe1405650 Communication: 0x00000000 'SeRmCommandPort'
  1 Port: 0xe141ef50 Connection: 0xe141ef50 Communication: 0x00000000 'SmApiPort'
  1 Port: 0xe13c5740 Connection: 0xe13c5740 Communication: 0x00000000 'ApiPort'
  1 Port: 0xe13d9550 Connection: 0xe13d9550 Communication: 0x00000000 'SbApiPort'
  3 Port: 0xe13d8830 Connection: 0xe141ef50 Communication: 0xe13d8910 '
80000004 Port: 0xe13d8910 Connection: 0xe141ef50 Communication: 0xe13d8830 '
  3 Port: 0xe13d8750 Connection: 0xe13d9550 Communication: 0xe13a4030 '
....
```

In the previous example, the port at address e14ae238 has no messages; that is, all messages have been picked up and no new messages have arrived.

```
kd> !lpc port e14ae238

Server connection port e14ae238 Name: ApiPort
Handles: 1 References: 107
  Server process : 84aa0140 (csrss.exe)
  Queue semaphore : 84a96da8
  Semaphore state 0 (0x0)
  The message queue is empty
  The LpcDataInfoChainHead queue is empty
```

In the previous example, the port at 0xe14ae238 has messages which have been queued, but not yet picked up by the server.

```
kd> !lpc port 0xe14ae238

Server connection port e14ae238 Name: ApiPort
Handles: 1 References: 108
  Server process : 84aa0140 (csrss.exe)
  Queue semaphore : 84a96da8
  Semaphore state 0 (0x0)
  Messages in queue:
  0000 e20d9b80 - Busy Id=0002249c From: 0584.0680 Context=00000021 [e14ae248 . e14ae248]
  Length=0098007c Type=00000001 (LPC_REQUEST)
          Data: 00000000 0002021e 00000584 00000680 002f0001 00000007
  The message queue contains 1 messages
  The LpcDataInfoChainHead queue is empty
```

The remaining Windows XP examples concern the other options that can be used with this extension.

```
kd> !lpc message 222be

!mca

5/31/2017 • 7 min to read • [Edit Online](#)

On an x86 target computer, the **!mca** extension displays the machine check architecture (MCA) registers. On an Itanium target computer, the **!mca** extension displays the MCA error record.

Syntax for x86 target computer

```
!mca
```

Syntax for Itanium target computer

```
!mca Address [Flags]
```

Parameters

Address

(Itanium target only) Specifies the address of the MCA error record.

Flags

(Itanium target only) Specifies the level of output. *Flags* can be any combination of the following bits. The default value is 0xFF, which displays all sections present in the log.

Bit 0 (0x1)

Displays the processor section.

Bit 1 (0x2)

Displays the platform-specific section.

Bit 2 (0x4)

Displays the memory section.

Bit 3 (0x8)

Displays the PCI component section.

Bit 4 (0x10)

Displays the PCI bus section.

Bit 5 (0x20)

Displays the SystemEvent Log section.

Bit 6 (0x40)

Displays the platform host controller section.

Bit 7 (0x80)

Displays to include the platform bus section.

DLL

Windows 2000	Kdextx86.dll
--------------	--------------

This extension command can only be used with an x86-based or Itanium target computer.

Remarks

On an Itanium target, **!mca** displays the MCA error record from the system abstraction layer (SAL). Here is an example of the output from this extension:

```
kd> !mca e0000165f3f58000
hal!HalpFeatureBits: 0xf [HAL_PERF_EVENTS|HAL_MCA_PRESENT|HAL_CMC_PRESENT|HAL_CPE_PRESENT]

CP	M/R/F/A	Manufacturer	SerialNumber	Features	Speed
0	1,5,31,0	GenuineIntel	0000000000000000	0000000000000001	1000 Mhz

On an x86 target, **!mca** displays the machine check registers supported by the active processor. It also displays basic CPU information (identical to that displayed by **!cpuinfo**). Here is an example of the output from this extension:

```
0: kd> !mca
MCE: Enabled, Cycle Address: 0x00000001699f7a00, Type: 0x0000000000000000

MCA: Enabled, Banks 5, Control Reg: Supported, Machine Check: None.
Bank  Error  Control Register      Status Register
0.  None   0x0000000000000007f  0x0000000000000000
1.  None   0x000000000fffffff  0x0000000000000000
2.  None   0x00000000000fffff  0x0000000000000000
3.  None   0x0000000000000007  0x0000000000000000
4.  None   0x0000000000003fff  0x0000000000000000

No register state available.

CP F/M/S Manufacturer      MHz Update Signature Features
0 15.5.0 SomeBrandName 1394 0000000000000000 a0017fff
```

Note that this extension requires private HAL symbols. Without these symbols, the extension will display the message "HalpFeatureBits not found" along with basic CPU information. For example:

```
kd> !mca
HalpFeatureBits not found
CP F/M/S Manufacturer  MHz Update Signature Features
 0 6.5.1 GenuineIntel 334 0000004000000000 00001fff
```

!memlist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!memlist** extension scans physical memory lists from the page frame number (PFN) database in order to check them for consistency.

```
!memlist Flags
```

Parameters

Flags

Specifies which memory lists to verify. At present, only one value has been implemented:

Bit 0 (0x1)

Causes the zeroed pages list to be verified.

DLL

Windows 2000	Kdexts.dll
Windows XP and later	Kdexts.dll

Remarks

At present, this extension will only check the zeroed pages list to make sure that all pages in that list are zeroed. The appropriate syntax is:

```
kd> !memlist 1
```

[Send comments about this topic to Microsoft](#)

!memusage

5/31/2017 • 3 min to read • [Edit Online](#)

The **!memusage** extension displays summary statistics about physical memory use.

Syntax

```
!memusage [Flags]
```

Parameters

Flags

Can be any one of the following values. The default is 0x0.

0x0

Displays general summary information, along with a more detailed description of the pages in the PFN database. See the Remarks section for an example of this type of output.

0x1

Displays only summary information about the modified no-write pages in the PFN database..

0x2

Displays only detailed information about the modified no-write pages in the PFN database.

0x8

Displays only general summary information about memory use.

Environment

Modes	kernel mode only
-------	------------------

DLL

Kdexts.dll

Additional Information

Physical memory statistics are collected from the Memory Manager's page frame number (PFN) database table.

This command takes a long time to run, especially if the target computer is running in 64-bit mode, due to the greater amount of data to obtain. While it is loading the PFN database, a counter shows its progress. To speed up this loading, increase the COM port speed with the **CTRL+A (Toggle Baud Rate)** key, or use the **.cache (Set Cache Size)** command to increase the cache size (perhaps to around 10 MB).

The **!memusage** command can also be used while performing [local kernel debugging](#).

Here is an example of the output from this extension:

```

kd> !memusage
loading PFN database
loading (98% complete)

Compiling memory usage data (100% Complete).
    Zeroed:    49 ( 196 kb)
    Free:      5 ( 20 kb)

```

The first column displays the address of the control area structure that describes each mapped structure. Use the **!ca** extension command to display these control areas.

Remarks

You can use the **!lvm** extension command to analyze virtual memory use. This extension is typically more useful than **!memusage**. For more information about memory management, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

The **!pfn** extension command can be used to display a particular page frame entry in the PFN database.

[Send comments about this topic to Microsoft](#)

!mps

5/31/2017 • 1 min to read • [Edit Online](#)

The **!mps** extension displays BIOS information for the Intel Multiprocessor Specification (MPS) of the target computer.

```
!mps [Address]
```

Parameters

Address

Specifies the hexadecimal address of the MPS table in the BIOS. If this is omitted, the information is obtained from the HAL. This will require HAL symbols.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

This extension command can only be used with an x86-based target computer.

Additional Information

For more information about BIOS debugging, see [Debugging BIOS Code](#). For more information about the MPS, refer to the appropriate version of the Intel MultiProcessor Specification.

[Send comments about this topic to Microsoft](#)

!mtrr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!mtrr** extension displays the contents of the MTRR register.

```
!mtrr
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

This extension command can only be used with an x86-based target computer.

[Send comments about this topic to Microsoft](#)

!npx

5/31/2017 • 1 min to read • [Edit Online](#)

The **!npx** extension displays the contents of the floating-point register save area.

```
!npx Address
```

Parameters

Address

Specifies the hexadecimal address of the FLOATING_SAVE_AREA structure.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

This extension command can only be used with an x86-based target computer.

[Send comments about this topic to Microsoft](#)

!ob, !od, !ow

5/26/2017 • 1 min to read • [Edit Online](#)

The **!ob**, **!od**, and **!ow** extension commands are obsolete. Use the **ob**, **od**, **ow (Output to Port)** commands instead.

[Send comments about this topic to Microsoft](#)

!object

5/31/2017 • 3 min to read • [Edit Online](#)

The **!object** extension displays information about a system object.

```
!object Address [Flags]
!object Path
!object 0 Name
!object -p
!object {-h|-?}
```

Parameters

Address

If the first argument is a nonzero hexadecimal number, it specifies the hexadecimal address of the system object to be displayed.

Flags

Specifies the level of detail in the command output.

Set *Flags* to a bitwise OR of these values:

0x0

Display object type.

0x1

Display object type, object name, and reference counts.

0x8

Display the contents of an object directory or the target of a symbolic link. This flag has an effect only if **0x1** is also set.

0x10

Display optional object headers.

0x20

Display the full path to a named object. This flag has an effect only if **0x1** is also set.

The *Flags* parameter is optional. The default value is 0x9.

Path

If the first argument begins with a backslash (\), **!object** interprets it as an object path name. When this option is used, the display will be arranged according to the directory structure used by the Object Manager.

Name

If the first argument is zero, the second argument is interpreted as the name of a class of system objects for which to display all instances.

-p

Display private object name spaces.

{-h|-?}

Display help for this command.

DLL

Kdexts.dll

Examples

This example passes the path of the \Device directory to **!object**. The output lists all objects in the \Device directory.

```
0: kd> !object \Device
Object: fffffc00b074166a0  Type: (fffffe0083b768690) Directory
  ObjectHeader: fffffc00b07416670 (new version)
  HandleCount: 0  PointerCount: 224
  Directory Object: fffffc00b074092e0  Name: Device

  Hash Address          Type           Name
  ----  -----          ----           --
  00    fffffe0083e6a61f0 Device        00000044
        fffffe0083dcc4050 Device        00000030
        fffffe0083d34f050 Device        NDMP2
        fffffe0083bdf7060 Device        NTPNP_PCI0002
        ...
        fffffe0083b85d060 Device        USBPDO-8
        fffffe0083d33d050 Device        USBFDO-6
        ...
        fffffe0083bdf0060 Device        NTPNP_PCI0001
```

Choose one of listed objects, say USBPDO-8. Pass the address of USBPDO-8 (fffffe0083b85d060) to **!object**. Set *Flags* to 0x0 to get minimal information.

```
0: kd> !object fffffe0083b85d060 0x0
Object: fffffe0083b85d060  Type: (fffffe0083b87df20) Device
  ObjectHeader: fffffe0083b85d030 (new version)
```

Include name and reference count information for the same object by setting *Flags* to 0x1.

```
0: kd> !object fffffe0083b85d060 0x1
Object: fffffe0083b85d060  Type: (fffffe0083b87df20) Device
  ObjectHeader: fffffe0083b85d030 (new version)
  HandleCount: 0  PointerCount: 6
  Directory Object: fffffc00b074166a0  Name: USBPDO-8
```

Get optional header information for the same object by setting *Flags* to 0x10.

```
0: kd> !object fffffe0083b85d060 0x10
Object: fffffe0083b85d060  Type: (fffffe0083b87df20) Device
  ObjectHeader: fffffe0083b85d030 (new version)
  Optional Headers:
    NameInfo(fffffe0083b85d010)
```

The following example calls **!object** twice for a Directory object. The first time, the contents of the directory are not displayed because the 0x8 flag is not set. The second time, the contents of the directory are displayed because both the 0x8 and 0x1 flags are set (Flags = 0x9).

```

0: kd> !object fffffc00b07481d00 0x1
Object: fffffc00b07481d00  Type: (fffffe0083b768690) Directory
  ObjectHeader: fffffc00b07481cd0 (new version)
  HandleCount: 0  PointerCount: 3
  Directory Object: fffffc00b07481eb0  Name: Filters

0: kd> !object fffffc00b07481d00 0x9
Object: fffffc00b07481d00  Type: (fffffe0083b768690) Directory
  ObjectHeader: fffffc00b07481cd0 (new version)
  HandleCount: 0  PointerCount: 3
  Directory Object: fffffc00b07481eb0  Name: Filters

  Hash  Address          Type           Name
  ----  -----          ----           --
  19    fffffe0083c5f56e0 Device        FltMgrMsg
  21    fffffe0083c5f5060 Device        FltMgr

```

The following example calls **!object** twice for a SymbolicLink object. The first time, the target of the symbolic link is not displayed because the 0x8 flag is not set. The second time, the target of the symbolic link is splayed because both the 0x8 and 0x1 flags are set (Flags = 0x9).

```

0: kd> !object fffffc00b07628fb0 0x1
Object: fffffc00b07628fb0  Type: (fffffe0083b769450) SymbolicLink
  ObjectHeader: fffffc00b07628f80 (new version)
  HandleCount: 0  PointerCount: 1
  Directory Object: fffffc00b074166a0  Name: Ip6

0: kd> !object fffffc00b07628fb0 0x9
Object: fffffc00b07628fb0  Type: (fffffe0083b769450) SymbolicLink
  ObjectHeader: fffffc00b07628f80 (new version)
  HandleCount: 0  PointerCount: 1
  Directory Object: fffffc00b074166a0  Name: Ip6
  Target String is '\Device\Tdx'

```

Additional Information

For information about objects and the object manager, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

See also

[Object Reference Tracing](#)

!obtrace

!handle

[Determining the ACL of an Object](#)

[Kernel-Mode Extension Commands](#)

[Send comments about this topic to Microsoft](#)

!obtrace

5/31/2017 • 1 min to read • [Edit Online](#)

The **!obtrace** extension displays object reference tracing data for the specified object.

```
!obtrace Object
```

Parameters

Object

A pointer to the object or a path.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For more information about the Global Flags utility (GFlags), see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

The object reference tracing feature of Windows records sequential stack traces whenever an object reference counter is incremented or decremented.

Before using this extension to display object reference tracing data, you must use [GFlags](#) to enable [object reference tracing](#) for the specified object. You can enable object reference tracing as a kernel flag (run-time) setting, in which the change is effective immediately, but disappears if you shut down or restart; or as a registry setting, which requires a restart, but remains effective until you change it.

Here is an example of the output from the **!obtrace** extension:

```

kd> !obtrace 0xfa96f700
Object: fa96f700      Image: cmd.exe

        nt!PsConvertToGuiThread+174
        nt!KiBBTUnexpectedRange+c
-----
References: 3, Dereferences 2

```

The primary indicators in the **!obtrace 0xfa96f700** display are listed in the following table.

PARAMETER	MEANING
Sequence	Represents the order of operations.
+/-	<p>Indicates a reference or a dereference operation.</p> <p>+1 indicates a reference operation.</p> <p>-1 indicates a dereference operation.</p> <p>+/- n indicates multiple reference/dereference operations.</p>

The object reference traces on x64-based target computers might be incomplete because it is not always possible to acquire stack traces at IRQL levels higher than PASSIVE_LEVEL.

You can stop execution at any time by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!openmaps

5/31/2017 • 1 min to read • [Edit Online](#)

The **!openmaps** extension displays the referenced buffer control blocks (BCBs) and virtual address control blocks (VACBs) for the specified shared cache map.

```
!openmaps Address [Flag]
```

Parameters

Address

Specifies the address of the shared cache map.

Flag

Determines which control blocks are displayed. If *Flag* is **1**, the debugger displays all control blocks. If *Flag* is **0**, the debugger displays only referenced control blocks. The default is **0**.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about cache management, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

For information about other cache management extensions, see the [!icchelp](#) extension.

[Send comments about this topic to Microsoft](#)

!pars

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pars** extension displays a specified processor application registers file.

```
!pars Address
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Address

Specifies the address of a processor application registers file.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium-based target computer.

[Send comments about this topic to Microsoft](#)

!pat

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pat** extension displays the Page Attribute Table (PAT) registers for the target processor.

```
!pat Flag  
!pat
```

Parameters

Flag

If *Flag* is set, the debugger verifies that the PAT feature is present before the PAT is displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

This extension command can only be used with an x86-based target computer.

[Send comments about this topic to Microsoft](#)

!pci

5/31/2017 • 5 min to read • [Edit Online](#)

The **!pci** extension displays the current status of the peripheral component interconnect (PCI) buses, as well as any devices attached to those buses.

```
!pci [Flags [Segment] [Bus [Device [Function [MinAddress MaxAddress]]]]]
```

Parameters

Flags

Specifies the level of output. Can be any combination of the following bits:

Bit 0 (0x1)

Causes a verbose display.

Bit 1 (0x2)

Causes the display to include all buses in the range from bus 0 (zero) to the specified *Bus*.

Bit 2 (0x4)

Causes the display to include information in raw byte format. If *MinAddress*, *MaxAddress*, or flag bit 0x8 is set, this bit is automatically set as well.

Bit 3 (0x8)

Causes the display to include information in raw DWORD format.

Bit 4 (0x10)

Causes the display to include invalid device numbers. If *Device* is specified, this flag is ignored.

Bit 5 (0x20)

Causes the display to include invalid function numbers.

Bit 6 (0x40)

Causes the display to include capabilities.

Bit 7 (0x80)

Causes the display to include Intel 8086 device-specific information.

Bit 8 (0x100)

Causes the display to include the PCI configuration space.

Bit 9 (0x200)

Causes the display to include segment information. When this bit is included, the *Segment* parameter must be included.

Bit 10 (0x400)

Causes the display to include all valid segments in the range from segment 0 to the specified segment. When this bit is included, the *Segment* parameter must be included.

Segment

Specifies the number of the segment to be displayed. Segment numbers range from 0 to 0xFFFF. If *Segment* is omitted, information about the primary segment (segment 0) is displayed. If *Flags* includes bit 10 (0x400), *Segment* specifies the highest valid segment to be displayed.

Bus

Specifies the bus to be displayed. *Bus* can range from 0 to 0xFF. If it is omitted, information about the primary bus (bus 0) is displayed. If *Flags* includes bit 1 (0x2), *Bus* specifies the highest bus number to be displayed.

Device

Specifies the slot device number for the device. If this is omitted, information about all devices is printed.

Function

Specifies the slot function number for the device. If this is omitted, all information about all device functions is printed.

MinAddress

Specifies the first address from which raw bytes or DWORDs are to be displayed. This must be between 0 and 0xFF.

MaxAddress

Specifies the last address from which raw bytes or DWORDs are to be displayed. This must be between 0 and 0xFF, and not less than *MinAddress*.

DLL

Windows 2000	Kext.dll Kdextx86.dll
Windows XP and later	Kext.dll

This extension command can only be used with an x86-based target computer.

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command and additional examples. For information about PCI buses, see the Windows Driver Kit (WDK) documentation.

Remarks

To edit the PCI configuration space, use [!ecb](#), [!ecd](#), or [!ecw](#).

The following example displays a list of all buses and their devices. This command will take a long time to execute. You will see a moving counter at the bottom of the display while the debugger scans the target system for PCI buses:

```
kd> !pci 2 ff
PCI Bus 0
00:0 8086:1237.02 Cmd[0106:.mb..s] Sts[2280:.....] Device Host bridge
0d:0 8086:7000.01 Cmd[0007:imb...] Sts[0280:.....] Device ISA bridge
0d:1 8086:7010.00 Cmd[0005:i.b...] Sts[0280:.....] Device IDE controller
0e:0 1011:0021.02 Cmd[0107:imb...] Sts[0280:.....] PciBridge 0->1-1 PCI-PCI bridge
10:0 102b:0519.01 Cmd[0083:im....] Sts[0280:.....] Device VGA compatible controller
PCI Bus 1
08:0 10b7:9050.00 Cmd[0107:imb..s] Sts[0200:.....] Device Ethernet
09:0 9004:8178.00 Cmd[0117:imb..s] Sts[0280:.....] Device SCSI controller
```

This example displays verbose information about the devices on the primary bus. The two-digit number at the beginning of each line is the device number; the one-digit number following it is the function number:

```

kd> !pci 1 0
PCI Bus 0
00:0 8086:1237.02 Cmd[0106:.mb..s] Sts[2280:.....] Device Host bridge
    cf8:80000000 IntPin:0 IntLine:0 Rom:0 cis:0 cap:0

0d:0 8086:7000.01 Cmd[0007:imb...] Sts[0280:.....] Device ISA bridge
    cf8:80006800 IntPin:0 IntLine:0 Rom:0 cis:0 cap:0

0d:1 8086:7010.00 Cmd[0005:i.b...] Sts[0280:.....] Device IDE controller
    cf8:80006900 IntPin:0 IntLine:0 Rom:0 cis:0 cap:0
    IO[4]:ffff1

0e:0 1011:0021.02 Cmd[0107:imb..s] Sts[0280:.....] PciBridge 0->1-1 PCI-PCI bridge
    cf8:80007000 IntPin:0 IntLine:0 Rom:0 cap:0 2sts:2280 BCtrl:6 ISA
    IO:f000-ffff Mem:fc000000-fdfffff PMem:fff00000-fffff

10:0 102b:0519.01 Cmd[0083:im....] Sts[0280:.....] Device VGA compatible controller
    cf8:80008000 IntPin:1 IntLine:9 Rom:80000000 cis:0 cap:0
    MEM[0]:fe800000 MPF[1]:fe000008

```

This example shows even more detailed information about bus 0 (zero), device 0x0D, and function 0x1, including the raw DWORDS from addresses between 0x00 and 0x3F:

```

kd> !pci f 0 d 1 0 3f
PCI Bus 0
0d:1 8086:7010.00 Cmd[0005:i.b...] Sts[0280:.....] Device IDE controller
    cf8:80006900 IntPin:0 IntLine:0 Rom:0 cis:0 cap:0
    IO[4]:ffff1
    00000000: 70108086 02800005 01018000 00002000
    00000010: 00000000 00000000 00000000 00000000
    00000020: 0000ffff 00000000 00000000 00000000
    00000030: 00000000 00000000 00000000 00000000

```

This example displays the configuration space for segment 1, bus 0, device 1:

```

0: kd> !pci 301 1 0 1
PCI Configuration Space (Segment:0001 Bus:00 Device:01 Function:00)
Common Header:
    00: VendorID      14e4 Broadcom Corporation
    02: DeviceID      16c7
    04: Command        0146 MemSpaceEn BusInitiate PERREn SERREn
    06: Status         02b0 CapList 66MHzCapable FB2BCapable DEVSELTiming:1
    .
    .
    .
    5a: MsgCtrl        64BitCapable MultipleMsgEnable:0 (0x1) MultipleMsgCapable:3 (0x8)

```

[Send comments about this topic to Microsoft](#)

!pciir

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pciir** extension displays the contents of the hardware routing of peripheral component interconnect (PCI) devices to interrupt controller inputs.

```
!pciir
```

DLL

Windows 2000	Kdextx86.dll
Windows XP	Kdexts.dll
Windows Server 2003	
Windows Vista and later	Unavailable

This extension command can only be used with an x86-based target computer that does not have the Advanced Configuration and Power Interface (ACPI) enabled.

Additional Information

For similar information on any ACPI-enabled computer, use the [!acpiirqarb](#) extension.

For information about PCI buses, see the Windows Driver Kit (WDK) documentation.

[Send comments about this topic to Microsoft](#)

!pcitree

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pcitree** extension displays information about PCI device objects, including child PCI buses and CardBus buses, and the devices attached to them.

```
!pcitree
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about PCI buses and PCI device objects, see the Windows Driver Kit (WDK) documentation.

Remarks

Here is an example:

```
kd> !pcitree

Bus 0x0 (FDO Ext fe517338)
0600 12378086 (d=0, f=0) devext fe4f4ee8 Bridge/HOST to PCI
0601 70008086 (d=d, f=0) devext fe4f4ce8 Bridge/PCI to ISA
0101 70108086 (d=d, f=1) devext fe4f4ae8 Mass Storage Controller/IDE
0604 00211011 (d=e, f=0) devext fe4f4788 Bridge/PCI to PCI

Bus 0x1 (FDO Ext fe516998)
0200 905010b7 (d=8, f=0) devext fe515ee8 Network Controller/Ethernet
0100 81789004 (d=9, f=0) devext fe515ce8 Mass Storage Controller/SCSI
0300 0519102b (d=10, f=0) devext fe4f4428 Display Controller/VGA

Total PCI Root busses processed = 1
```

To understand this display, consider the final device shown. Its base class is 03, its subclass is 00, its Device ID is 0x0519, and its Vendor ID is 0x102B. These values are all intrinsic to the device itself.

The number after "d=" is the device number; the number after "f=" is the function number. After "devext" is the device extension address, 0xFE4F4428. Finally, the base class name and the subclass name appear.

To obtain more information about a device, use the **!devext** extension command with the device extension address as the argument. For this particular device, the command to use would be:

```
kd> !devext fe4f4428 pci
```

If the **!pcitree** extension generates an error, this often means that your PCI symbols were not loaded properly. Use [.reload pci.sys](#) to fix this problem.

[Send comments about this topic to Microsoft](#)

!pcm

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pcm** extension displays the specified private cache map. This extension is only available in Windows 2000.

!pcm *Address*

Parameters

Address

Specifies the address of the private cache map.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable (see Remarks section)

Additional Information

For information about cache management, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

For information about other cache management extensions, see the [!icchelp](#) extension reference.

Remarks

This extension is supported only in Windows 2000. In Windows XP and later versions of Windows, use the [dt nt!_PRIVATE_CACHE_MAP Address](#) command.

[Send comments about this topic to Microsoft](#)

!pcr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pcr** extension displays the current status of the Processor Control Region (PCR) on a specific processor.

```
!pcr [Processor]
```

Parameters

Processor

Specifies the processor to retrieve the PCR information from. If *Processor* is omitted, the current processor is used.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about the PCR and the PRCB, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.(This book may not be available in some languages and countries.)

Remarks

The processor control block (PRCB) is an extension of the PCR. It can be displayed with the **!prcb** extension.

Here is an example of the **!pcr** extension on an x86 target computer:

```
kd> !pcr 0
KPCR for Processor 0 at ffdff000:
Major 1 Minor 1
  NtTib.ExceptionList: 801626e0
    NtTib.StackBase: 801628f0
    NtTib.StackLimit: 8015fb00
    NtTib.SubSystemTib: 00000000
    NtTib.Version: 00000000
    NtTib.UserPointer: 00000000
    NtTib.SelfTib: 00000000

      SelfPcr: ffdff000
      Prcb: ffdff120
      Irql: 00000000
      IRR: 00000000
      IDR: ffffffff
  InterruptMode: 00000000
    IDT: 80043400
    GDT: 80043000
    TSS: 803cc000

  CurrentThread: 8015e8a0
  NextThread: 00000000
  IdleThread: 8015e8a0

  DpcQueue: 0x80168ee0 0x80100d04 ntoskrnl!KiTimerExpiration
```

One of the entries in this display shows the interrupt request level (IRQL). The **!pcr** extension shows the current IRQL, but the current IRQL is usually not of much interest. The IRQL that existed just before the bug check or debugger connection is more interesting. This is displayed by **!irql**, which is only available on computers running Windows Server 2003 or later versions of Windows.

[Send comments about this topic to Microsoft](#)

!pcrs

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pcrs** extension displays the Intel Itanium-specific processor control registers.

`!pcrs Address`

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Address

Specifies the address of a processor control registers file.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium-based target computer.

Remarks

Do not confuse the **!pcrs** extension with the [!pcr](#) extension, which displays the current status of the processor control region.

[Send comments about this topic to Microsoft](#)

!pfn

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pfn** extension displays information about a specific page frame or the entire page frame database.

```
!pfn PageFrame
```

Parameters

PageFrame

Specifies the hexadecimal number of the page frame to be displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about page tables, page directories, and page frames, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

The page frame number for a virtual address can be obtained by using the **!pte** extension.

Here is an example of the output from this extension:

```
kd> !pte 801544f4
801544F4 - PDE at C0300800      PTE at C0200550
    contains 0003B163      contains 00154121
    pfn 3b G-DA--KWF      pfn 154 G--A--KRV

kd> !pfn 3b
PFN 0000003B at address 82350588

Modified
```

[Send comments about this topic to Microsoft](#)

!pmc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pmc** extension displays the Performance Monitor Counter (PMC) register at the specified address.

This extension is supported only on an Itanium-based target computer.

```
!pmc [- Option] Expression [DisplayLevel]
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Option

Can be any one of the following values:

gen

Displays the register as a generic PMC register.

btb

Displays the register as a branch trace buffer (BTB) PMC register.

Expression

Specifies the hexadecimal address of a PMC. The expressions **@kpfcgen** and **@kpfcbtb** can be used as values for this parameter.

If *Expression* is **@kpfcgen**, the debugger displays the current processor PMC register as a generic PMC register. You can also display the current processor PMC register as a generic PMC register by setting *Option* to **gen** and using **@kpfc4**, **@kpfc5**, **@kpfc6**, or **@kpfc7** for the *Expression* value.

If *Expression* is **@kpfcbtb**, the debugger displays the current processor PMC register as a BTB PMC register. You can also display the current processor PMC register as a BTB PMC register by setting *Option* to **btb** and using **@kpfc12** for the *Expression* value.

DisplayLevel

Can be any one of the following values:

0

Displays only the values of each PMC register field. This is the default.

1

Displays detailed information about the PMC register fields that are not reserved or ignored.

2

Displays detailed information about all PMC register fields, including those that are ignored or reserved.

DLL

Windows 2000	Unavailable
--------------	-------------

Windows XP and later

Kdexts.dll

[Send comments about this topic to Microsoft](#)

!pmssa

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pmssa** extension displays a specified processor Minimal State Save Area (also known as Min-StateSave Area).

This extension can only be used with an Itanium-based target computer.

```
!pmssa Address
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Address

Specifies the address of a processor Min-StateSave Area.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

[Send comments about this topic to Microsoft](#)

!powertriage

5/31/2017 • 2 min to read • [Edit Online](#)

The !powertriage extension displays summary information about the system and device power related components. It also provides links to related commands that can be used to gather additional information. The !powertriage command has no parameters. This command can be used with both live kernel-mode debugging and for crash dump file analysis.

Syntax

```
!powertriage
```

Parameters

None

DLL

Windows 10 and later	Kdexts.dll
-----------------------------	------------

Remarks

The !powertriage extension displays the following information.

1. Power state of the device node along with !podev for all the device objects.
2. Links to [!rcdrkd.rcdrlogdump](#) if the driver has enabled the IFR. For more information about IFR, see [Using Inflight Trace Recorder \(IFR\) in KMDF and UMDF 2 Drivers](#).
3. Links to [!wdfkd.wdfdriverinfo](#) and [!wdfkd.wdflogdump](#) for WDF drivers.
4. Links to !fxdevice for PoFx devices. For more information about PoFX, see [Overview of the Power Management Framework](#). Here is example output from the !powertriage command.

```
kd> !powertriage

Dump File Power Failure Analysis

The !powertriage extension can be useful in examining system crashes related to incorrect power state information. For example, in the case of [Bug Check 0x9F: DRIVER_POWER_STATE_FAILURE](#), the extension will display all the allocated power IRPs, the associated device stacks along with:

1. Links to the **!irp** command for the related IRPs.
2. Links to the **!findthreads** command with the related IRP. The IRP is added as part of the search criteria and displays the threads starting with higher correlation to the search criteria threads listed first. Dumping all device stacks with power IRPs can help in debugging cases where !analyze has not been able to correctly identify the IRP associated with the crash.

[Send comments about this topic to Microsoft](#)

!pnpevent

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pnpevent** extension displays the Plug and Play device event queue.

```
!pnpevent [DeviceEvent]
```

Parameters

DeviceEvent

Specifies the address of a device event to display. If this is zero or omitted, the tree of all device events in the queue is displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about Plug and Play drivers, see the Windows Driver Kit (WDK) documentation.

See also

[Plug and Play and Power Debugger Commands](#)

[Send comments about this topic to Microsoft](#)

!pocaps

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pocaps** extension displays the power capabilities of the target computer.

```
!pocaps
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

To view the system's power policy, use the [!popolicy](#) extension command. For information about power capabilities and power policy, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Here is an example of this command's output:

```
kd> !pocaps
PopCapabilities @ 0x8016b100

title: pool extension command description: The pool extension displays information about a specific pool allocation or about the entire system-wide pool. ms.assetid: 1c224e0c-d50c-487e-8238-9be054368ac2 keywords: ["pool", "pool", See "memory\"", "pooltag.txt file", "pool tag", "memory, pool tag", "pool Windows Debugging"] ms.author: windowsdriverdev ms.date: 05/23/2017 ms.topic: article ms.prod: windows-hardware ms.technology: windows-devices topic_type:

- apiref api_name:
- pool api_type:

- NA

!pool

The **!pool** extension displays information about a specific pool allocation or about the entire system-wide pool.

```
!pool [Address [Flags]]
```

Parameters

Address

Specifies the pool entry to be displayed. If *Address* is -1, this command displays information about all heaps in the process.

If *Address* is 0 or omitted, this command displays information about the process heap.

Flags

Specifies the level of detail to be used. This can be any combination of the following bit values; the default is zero:

Bit 0 (0x1)

Causes the display to include the pool contents, not just the pool headers.

Bit 1 (0x2)

Causes the display to suppress pool header information for all pools, except the one that actually contains the specified *Address*.

Bit 31 (0x80000000)

(Windows XP and later) Suppresses the description of the pool type and pool tag in the display.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about memory pools, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows*

Internals, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

In Windows XP and later versions of Windows, the **!pool** extension displays the pool tag associated with each allocation. The owner of that pool tag is also displayed. This display is based on the contents of the pooltag.txt file. This file is located in the triage subdirectory of your Debugging Tools for Windows installation. If you want, you can edit this file to add additional pool tags relevant to your project.

Warning If you install an updated version of Debugging Tools for Windows in the same directory as the current version, it overwrites all of the files in that directory, including pooltag.txt. If you modify or replace the sample pooltag.txt file, be sure to save a copy of it to a different directory. After reinstalling the debuggers, you can copy the saved pooltag.txt over the default version.

If the **!pool** extension reports pool corruption, you should use **!poolval** to investigate.

Here is an example. If *Address* specifies 0xE1001050, the headers of all pools in this block are displayed, and 0xE1001050 itself is marked with an asterisk (*).

```
kd> !pool e1001050
e1001000 size: 40 previous size: 0 (Allocated) MmDT
e1001040 size: 10 previous size: 40 (Free) Mm
*e1001050 size: 10 previous size: 10 (Allocated) *ObDi
e1001060 size: 10 previous size: 10 (Allocated) ObDi
e1001070 size: 10 previous size: 10 (Allocated) Symt
e1001080 size: 40 previous size: 10 (Allocated) ObDm
e10010c0 size: 10 previous size: 40 (Allocated) ObDi
....
```

In this example, the right-most column shows the pool tag. The column to the left of this shows whether the pool is free or allocated.

The following command shows the pool headers and pool contents:

```
kd> !pool e1001050 1
e1001000 size: 40 previous size: 0 (Allocated) MmDT
e1001008 ffffffff 0057005c 004e0049 004f0044
e1001018 ffffffff 0053005c 00730079 00650074

e1001040 size: 10 previous size: 40 (Free) Mm
e1001048 ffffffff e1007ba8 e1501a58 01028101
e1001058 ffffffff 00000000 e1000240 01028101

*e1001050 size: 10 previous size: 10 (Allocated) *ObDi
e1001058 ffffffff 00000000 e1000240 01028101
e1001068 ffffffff 00000000 e10009c0 01028101

e1001060 size: 10 previous size: 10 (Allocated) ObDi
e1001068 ffffffff 00000000 e10009c0 01028101
e1001078 ffffffff 00000000 00000000 04028101

....
```

[Send comments about this topic to Microsoft](#)

!poolfind

5/31/2017 • 2 min to read • [Edit Online](#)

The **!poolfind** extension finds all instances of a specific pool tag in either nonpaged or paged memory pools.

```
!poolfind TagString [PoolType]  
!poolfind TagValue [PoolType]
```

Parameters

TagString

Specifies the pool tag. *TagString* is a case-sensitive ASCII string. The asterisk (*) can be used to represent any number of characters; the question mark (?) can be used to represent exactly one character. Unless an asterisk is used, *TagString* must be exactly four characters in length.

TagValue

Specifies the pool tag. *TagValue* must begin with "0x", even if the default radix is 16. If this parameter begins with any other value (including "0X") it will be interpreted as an ASCII tag string.

PoolType

Specifies the type of pool to be searched. The following values are permitted:

0

Specifies nonpaged memory pool. This is the default.

1

Specifies paged memory pool.

2

Specifies the special pool.

4

(Windows XP and later) Specifies the session pool.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about memory pools and pool tags, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

This command can take a significant amount of time to execute, depending on the size of pool memory that must be searched. To speed up this execution, increase the COM port speed with the **CTRL+A (Toggle Baud Rate)** key, or use the **.cache (Set Cache Size)** command to increase the cache size (to approximately 10 MB).

The pool tag is the same tag passed to the **ExAllocateXxx** family of routines.

Here is an example. The entire nonpaged pool is searched and then the paged pool is searched, but the command is terminated before completion (after an hour of operation):

```
kd> !poolfind SeSd 0

Scanning large pool allocation table for Tag: SeSd (827d1000 : 827e9000)

Searching NonPaged pool (823b1000 : 82800000) for Tag: SeSd

...terminating - searched pool to e1224000
kd>
```

[Send comments about this topic to Microsoft](#)

!poolused

5/31/2017 • 3 min to read • [Edit Online](#)

The **!poolused** extension displays memory use summaries, based on the tag used for each pool allocation.

```
!poolused [Flags [TagString]]
```

Parameters

Flags

Specifies the amount of output to be displayed and the method of sorting the output. This can be any combination of the following bit values, except that bits 1 (0x2) and 2 (0x4) cannot be used together. The default is 0x0, which produces summary information, sorted by pool tag.

Bit 0 (0x1)

Displays more detailed (verbose) information.

Bit 1 (0x2)

Sorts the display by the amount of nonpaged memory use.

Bit 2 (0x4)

Sorts the display by the amount of paged memory use.

Bit 3 (0x8)

(Windows Server 2003 and later) Displays the session pool instead of the standard pool.

Note You can use the **!session** command to switch between sessions.

TagString

Specifies the pool tag. *TagString* is a case-sensitive ASCII string. The asterisk (*) can be used to represent any number of characters; the question mark (?) can be used to represent exactly one character. Unless an asterisk is used, *TagString* must be exactly four characters in length.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about memory pools and pool tags, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The **!poolused** extension gathers data from the pool tagging feature of Windows. Pool tagging is permanently enabled on Windows Server 2003 and later versions of Windows. On Windows XP and earlier versions of Windows, you must enable pool tagging by using **Gflags**.

If you stop executing the extension before it completes, the debugger displays partial results.

The display for this command shows the memory use for each tag in paged pool and nonpaged pool. In both cases, the display includes the number of currently outstanding allocations for the given tag and the number of bytes being consumed by those allocations.

Here is a partial example of the output from this extension:

```
0: kd> !poolused
Sorting by Tag

Pool Used:
      NonPaged          Paged

!poolval

5/31/2017 • 1 min to read • [Edit Online](#)

The **!poolval** extension analyzes the headers for a pool page and diagnoses any possible corruption. This extension is only available in Windows XP and later versions.

```
!poolval Address [DisplayLevel]
```

Parameters

Address

Specifies the address of the pool whose header is to be analyzed.

DisplayLevel

Specifies the information to include in the display. This can be any of the following values (the default is zero):

0

Causes basic information to be displayed.

1

Causes basic information and linked header lists to be displayed.

2

Causes basic information, linked header lists, and basic header information to be displayed.

3

Causes basic information, linked header lists, and full header information to be displayed.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about memory pools, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

[Send comments about this topic to Microsoft](#)

!popolicy

5/31/2017 • 1 min to read • [Edit Online](#)

The **!popolicy** extension displays the power policy of the target computer.

```
!popolicy [Address]
```

Parameters

Address

Specifies the address of the power policy structure to display. If this is omitted, then nt!PopPolicy is displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

To view the system's power capabilities, use the **!pocaps** extension command. For information about power capabilities and power policy, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Here is an example of this command's output:

```
kd> !popolicy

!ppmperf

6/9/2017 • 1 min to read • [Edit Online](#)

The **!ppmperf** command displays power and performance constraint information.

```
!ppmperf
```

Parameters

None

DLL

kedexts.dll

NOTE: This command is not supported on all versions of Windows, such as Windows 10, Version 1703.

[Send comments about this topic to Microsoft](#)

!ppmperfpolicy

6/9/2017 • 1 min to read • [Edit Online](#)

The **!ppmperfpolicy** command is no longer supported, use the [!ppmsettings](#) command instead.

```
!ppmperfpolicy
```

Parameters

None

DLL

Kdexts.dll

[Send comments about this topic to Microsoft](#)

!ppmstate

6/9/2017 • 1 min to read • [Edit Online](#)

The **!ppmstate** command displays power state information.

```
!ppmstate
```

Parameters

None

DLL

Kdexts.dll

NOTE: This command is not supported on all versions of Windows, such as Windows 10, Version 1703.

[Send comments about this topic to Microsoft](#)

!ppmstate

6/9/2017 • 1 min to read • [Edit Online](#)

The **!ppmstate** command displays power state information.

```
!ppmstate
```

Parameters

None

DLL

Kdexts.dll

NOTE: This command is not supported on all versions of Windows, such as Windows 10, Version 1703.

[Send comments about this topic to Microsoft](#)

!prcb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!prcb** extension displays the processor control block (PRCB).

```
!prcb [Processor]
```

Parameters

Processor

Specifies the processor to retrieve the PRCB information from. If *Processor* is omitted, processor zero will be used.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about the PCR and the PRCB, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The PRCB is an extension of the processor control region (PCR). To display the PCR, use the [!pcr](#) extension.

Here is an example:

```
kd> !prcb
PRCB for Processor 0 at e0000000818ba000:
Threads-- Current e0000000818bbe10 Next 0000000000000000 Idle e0000000818bbe10
Number 0 SetMember 00000001
Interrupt Count -- 0000b81f
Times -- Dpc 00000028 Interrupt 000003ff
          Kernel 00005ef4 User 00000385
```

[Send comments about this topic to Microsoft](#)

!process

5/31/2017 • 7 min to read • [Edit Online](#)

The `!process` extension displays information about the specified process, or about all processes, including the `EPROCESS` block.

This extension can be used only during kernel-mode debugging.

Syntax

```
!process [/s Session] [/m Module] [Process [Flags]]  
!process [/s Session] [/m Module] 0 Flags ImageName
```

Parameters

/s **** *Session*

Specifies the session that owns the desired process.

/m **** *Module*

Specifies the module that owns the desired process.

Process

Specifies the hexadecimal address or the process ID of the process on the target computer.

The value of *Process* determines whether the `!process` extension displays a process address or a process ID. If *Process* is omitted in any version of Windows, the debugger displays data only about the current system process. If *Process* is 0 and *ImageName* is omitted, the debugger displays information about all active processes.

Flags

Specifies the level of detail to display. *Flags* can be any combination of the following bits. If *Flags* is 0, only a minimal amount of information is displayed. The default varies according to the version of Windows and the value of *Process*. The default is 0x3 if *Process* is omitted or if *Process* is either 0 or -1; otherwise, the default is 0xF.

Bit 0 (0x1)

Displays time and priority statistics.

Bit 1 (0x2)

Displays a list of threads and events associated with the process, and their wait states.

Bit 2 (0x4)

Displays a list of threads associated with the process. If this is included without Bit 1 (0x2), each thread is displayed on a single line. If this is included along with Bit 1, each thread is displayed with a stack trace.

Bit 3 (0x8)

(Windows XP and later) Displays the return address, the stack pointer, and (on Itanium-based systems) the **bsp** register value for each function. The display of function arguments is suppressed.

Bit 4 (0x10)

(Windows XP and later) Sets the process context equal to the specified process for the duration of this command. This results in a more accurate display of thread stacks. Because this flag is equivalent to using [.process /p /r](#) for the specified process, any existing user-mode module list will be discarded. If *Process* is

zero, the debugger displays all processes, and the process context is changed for each one. If you are only displaying a single process and its user-mode state has already been refreshed (for example, with **.process /p /r**), it is not necessary to use this flag. This flag is only effective when used with Bit 0 (0x1).

ImageName

Specifies the name of the process to be displayed. The debugger displays all processes whose executable image names match *ImageName*. The image name must match that in the EPROCESS block. In general, this is the executable name that was invoked to start the process, including the file extension (usually .exe), and truncated after the fifteenth character. There is no way to specify an image name that contains a space. When *ImageName* is specified, *Process* must be zero.

DLL

Kdexts.dll

Additional Information

For information about processes in kernel mode, see [Changing Contexts](#). For more information about analyzing processes and threads, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

The following is an example of a **!process 0 0** display:

```
kd> !process 0 0
**** NT ACTIVE PROCESS DUMP ****
PROCESS 80a02a60  Cid: 0002    Peb: 00000000  ParentCid: 0000
    DirBase: 00006e05  ObjectTable: 80a03788  TableSize: 150.
    Image: System
PROCESS 80986f40  Cid: 0012    Peb: 7ffde000  ParentCid: 0002
    DirBase: 000bd605  ObjectTable: 8098fce8  TableSize: 38.
    Image: smss.exe
PROCESS 80958020  Cid: 001a    Peb: 7ffde000  ParentCid: 0012
    DirBase: 0008b205  ObjectTable: 809782a8  TableSize: 150.
    Image: csrss.exe
PROCESS 80955040  Cid: 0020    Peb: 7ffde000  ParentCid: 0012
    DirBase: 00112005  ObjectTable: 80955ce8  TableSize: 54.
    Image: winlogon.exe
PROCESS 8094fce0  Cid: 0026    Peb: 7ffde000  ParentCid: 0020
    DirBase: 00055005  ObjectTable: 80950cc8  TableSize: 222.
    Image: services.exe
PROCESS 8094c020  Cid: 0029    Peb: 7ffde000  ParentCid: 0020
    DirBase: 000c4605  ObjectTable: 80990fe8  TableSize: 110.
    Image: lsass.exe
PROCESS 809258e0  Cid: 0044    Peb: 7ffde000  ParentCid: 0026
    DirBase: 001e5405  ObjectTable: 80925c68  TableSize: 70.
    Image: SPOOLSS.EXE
```

The following table describes some of the elements of the **!process 0 0** output.

ELEMENT	MEANING
Process address	The eight-character hexadecimal number after the word PROCESS is the address of the EPROCESS block. In the final entry in the preceding example, the process address is 0x809258E0.

ELEMENT	MEANING
Process ID (PID)	The hexadecimal number after the word Cid. In the final entry in the preceding example, the PID is 0x44, or decimal 68.
Process Environment Block (PEB)	The hexadecimal number after the word Peb is the address of the process environment block. In the final entry in the preceding example, the PEB is located at address 0x7FFDE000.
Parent process PID	The hexadecimal number after the word ParentCid is the PID of the parent process. In the final entry in the preceding example, the parent process PID is 0x26, or decimal 38.
Image	The name of the module that owns the process. In the final entry in the preceding example, the owner is spoolss.exe. In the first entry, the owner is the operating system itself.
Process object address	The hexadecimal number after the word ObjectTable. In the final entry in the preceding example, the address of the process object is 0x80925c68.

To display full details on one process, set *Flags* to 7. The process itself can be specified by setting *Process* equal to the process address, setting *Process* equal to the process ID, or setting *ImageName* equal to the executable image name. Here is an example:

```

kd> !process fb667a00 7
PROCESS fb667a00 Cid: 0002 Peb: 00000000 ParentCid: 0000
  DirBase: 00030000 ObjectTable: e1000f88 TableSize: 112.

    fb26ed3c 801289d9 80144fc0 00000008 00000000 KeWaitForSingleObject+0x1c2

```

Note that the address of the process object can be used as input to other extensions, such as [!handle](#), to obtain further information.

The following table describes some of the elements in the previous example.

ELEMENT	MEANING
WAIT	The parenthetical comment after this heading gives the reason for the wait. The command dt nt!_KWAIT_REASON will display a list of all wait reasons.
Elapsed Time	Lists the amount of time that has elapsed since the process was created. This is displayed in units of Hours:Minutes:Seconds.Milliseconds.
User Time	Lists the amount of time the process has been running in user mode. If the value for UserTime is exceptionally high, it might identify a process that is depleting system resources. Units are the same as those of ElapsedTime.

ELEMENT	MEANING
KernelTime	Lists the amount of time the process has been running in kernel mode. If the value for KernelTime is exceptionally high, it might identify a process that is depleting system resources. Units are the same as those of ElapsedTime.
Working Set sizes	Lists the current, minimum and maximum working set size for the process, in pages. An exceptionally large working set size can be a sign of a process that is leaking memory or depleting system resources.
QuotaPoolUsage entries	Lists the paged and nonpaged pool used by the process. On a system with a memory leak, looking for excessive nonpaged pool usage on all the processes can tell you which process has the memory leak.
Clone	Indicates whether or not the process was created by the POSIX or Interix subsystems.
Private	Indicates the number of private (non-sharable) pages currently being used by the process. This includes both paged in and paged out memory.

In addition to the process list information, the thread information contains a list of the resources on which the thread has locks. This information is listed in the third line of output after the thread header. In this example, the thread has a lock on one resource, a SynchronizationEvent with an address of 80144fc0. By comparing this address to the list of locks shown by the **!kdext*.locks** extension, you can determine which threads have exclusive locks on resources.

The **Istacks** extension gives a brief summary of the state of every thread. This can be used instead of the !process extension to get a quick overview of the system, especially when debugging multithread issues, such as resource conflicts or deadlocks.

[Send comments about this topic to Microsoft](#)

!processfields

5/31/2017 • 1 min to read • [Edit Online](#)

The **!processfields** extension displays the names and offsets of the fields within the executive process (EPROCESS) block.

```
!processfields
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable (see the Remarks section)

Additional Information

For information about the EPROCESS block, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

This extension command is not available in Windows XP or later versions of Windows. Instead, use the [dt \(Display Type\)](#) command to show the EPROCESS structure directly:

```
kd> dt nt!_EPROCESS
```

Here is an example of **!processfields** from a Windows 2000 system:

```
kd> !processfields
EPROCESS structure offsets:

!processirps

5/31/2017 • 1 min to read • [Edit Online](#)

The **!processirps** extension displays information about I/O request packets (IRPs) associated with processes.

```
!processirps
!processirps ProcessAddress [Flags]
```

Parameters

**** *ProcessAddress*

The address of a process. If you specify *ProcessAddress*, only IRPs associated with that process are displayed. If you do not specify *ProcessAddress*, IRPs for all processes are displayed.

**** *Flags*

A bitwise OR of one or more of the following flags.

Bit 0 (0x1)

Display IRPs queued to threads.

Bit 1 (0x2)

Display IRPs queued to file objects.

If you specify *Flags*, you must also specify *ProcessAddress*. If you do not specify *Flags*, IRPs queued to both threads and file objects are displayed.

DLL

kdexts.dll

Remarks

This command enables you to quickly identify any queued IRPs for a process, both those that are queued to threads and those that are queued to file objects. IRPs are queued to a file object when the file object has a completion port associated with it.

Examples

You can use **!process** command to get process addresses. For example, you could get the process address for explorer.exe.

```
2: kd> !process 0 0
**** NT ACTIVE PROCESS DUMP ****
...
PROCESS ffffffa800688c940
  SessionId: 1  Cid: 0bbc  Peb: 7f70da5e000  ParentCid: 0b84
  DirBase: 2db10000  ObjectTable: fffff8a0025bd440  HandleCount: 1056.
  Image: explorer.exe
```

Now you can pass the process address for explorer.exe to the **!processirps** command. The following output shows that explorer.exe has IRPs queued to threads and IRPs queued to file objects.

```
2: kd> !processirps ffffffa800688c940
**** PROCESS ffffffa800688c940 (Image: explorer.exe) ****

Checking threads for IRPs.

Thread ffffffa800689f080:

IRP ffffffa80045ccc10 - Owned by \FileSystem\Ntfs for device ffffffa8004f5c030
IRP ffffffa800454f650 - Owned by \FileSystem\Ntfs for device ffffffa8004f5c030
...
IRP ffffffa80068e9c10 - Owned by \FileSystem\Ntfs for device ffffffa8004f5c030
```

```
Checking file objects for IRPs.
```

```
FileObject ffffffa80068795e0 (handle 8bc):
IRP ffffffa8006590cf0 - Owned by \Driver\DeviceApi for device DeviceApi (fffffa800363ae40)
```

```
...
```

```
FileObject ffffffa8005bf59c0 (handle 900):
```

```
IRP ffffffa8006659010 - Owned by \Driver\DeviceApi for device DeviceApi (fffffa800363ae40)
```

[Send comments about this topic to Microsoft](#)

!psp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!psp** extension displays the processor state parameter (PSP) register at the specified address.

This extension is supported only on Itanium-based target computers.

```
!psp Address [DisplayLevel]
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Address

Specifies the hexadecimal address of the PSP register to display.

DisplayLevel

Can be any one of the following options:

0

Displays only the values of each PSP field. This is the default.

1

Displays more in-depth information on each of the PSP fields that is not reserved or ignored.

2

Displays more in-depth information on all of the PSP fields, including those that are ignored or reserved.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

[Send comments about this topic to Microsoft](#)

!pte

5/31/2017 • 3 min to read • [Edit Online](#)

The **!pte** extension displays the page table entry (PTE) and page directory entry (PDE) for the specified address.

Syntax

```
!pte VirtualAddress
!pte PTE
!pte LiteralAddress 1
```

Parameters

VirtualAddress

Specifies the virtual address whose page table is desired.

PTE

Specifies the address of an actual PTE.

*LiteralAddress **** 1*

Specifies the address of an actual PTE or PDE.

DLL

Kdexts.dll

Additional Information

For information about page tables, page directories, and an explanation of the status bits, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

If one parameter is supplied and this parameter is an address in the region of memory where the page tables are stored, the debugger treats this as the *PTE* parameter. This parameter is taken as the actual address of the desired PTE, and the debugger will display this PTE and the corresponding PDE.

If one parameter is supplied and this parameter is not an address in this region, the debugger treats this as the *VirtualAddress* parameter. The PTE and PDE that hold the mapping for this address are displayed.

If two parameters are supplied and the second parameter is **1** (or any other small number), the debugger treats the first parameter as *LiteralAddress*. This address is interpreted as the actual address of a PTE and also as the actual address of a PDE, and the corresponding (and possibly invalid) data will be shown.

(x86 or x64 target computer only) If two parameters are supplied and the second parameter is greater than the first, the debugger treats the two parameters as *StartAddress* and *EndAddress*. The command then displays the PTEs for each page in the specified memory range.

For a list of all system PTEs, use the **!sysptes** extension.

Here is an example from an x86 target computer:

```

kd> !pte 801544f4
801544F4 - PDE at C0300800      PTE at C0200550
contains 0003B163      contains 00154121
pfn 3b G-DA--KVV  pfn 154 G--A--KRV

```

The first line of this example restates the virtual address being investigated. It then gives the virtual address of the PDE and the PTE, which contain information about the virtual-physical mapping of this address.

The second line gives the actual contents of the PDE and the PTE.

The third line takes these contents and analyzes them, breaking them into the page frame number (PFN) and the status bits.

See the [!pfn](#) extension or the [Converting Virtual Addresses to Physical Addresses](#) section for information about how to interpret and use the PFN.

On an x86 or x64 target computer, the status bits for the PDE and the PTE are shown in the following table. The **!pte** display indicates these bits with capital letters or dashes, and adds additional information as well.

BIT	DISPLAY WHEN SET	DISPLAY WHEN CLEAR	MEANING
0x200	C	-	Copy on write.
0x100	G	-	Global.
0x80	L	-	Large page. This only occurs in PDEs, never in PTEs.
0x40	D	-	Dirty.
0x20	A	-	Accessed.
0x10	N	-	Cache disabled.
0x8	T	-	Write-through.
0x4	U	K	Owner (user mode or kernel mode).
0x2	W	R	Writeable or read-only. Only on multiprocessor computers and any computer running Windows Vista or later.
0x1	V		Valid.

BIT	DISPLAY WHEN SET	DISPLAY WHEN CLEAR	MEANING
	E	-	Executable page. For platforms that do not support a hardware execute/noexecute bit, including many x86 systems, the E is always displayed.

On an Itanium target computer, the status bits for the PDE and the PTE are slightly different from those of the PPE. The Itanium PPE bits are as follows:

DISPLAY WHEN SET	DISPLAY WHEN CLEAR	MEANING
V		Valid.
U	K	Owner (user mode or kernel mode).
D	-	Dirty.
A	-	Accessed.
W	R	Writable or read-only. Only on multiprocessor computers and any computer running Windows Vista or later.
E	-	Execute.
C	-	Copy on write.

[Send comments about this topic to Microsoft](#)

!pte2va

5/31/2017 • 1 min to read • [Edit Online](#)

The **!pte2va** extension displays the virtual address that corresponds to the specified page table entry (PTE).

```
!pte2va Address
```

Parameters

Address

Specifies the PTE.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about page tables and PTEs, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

To examine the contents of a specific PTE, use the [!pte](#) extension.

Here is an example of the output from the **!pte2va** extension:

```
kd> !pte2va 9230
000800000248c000
```

[Send comments about this topic to Microsoft](#)

!ptov

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ptov** extension displays the entire physical-to-virtual map for a given process.

```
!ptov DirBase
```

Parameters

DirBase

Specifies the directory base for the process. To determine the directory base, use the **!process** command, and look at the value displayed for DirBase.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

Here is an example. First, use **.process** and **!process** to determine the directory base of the current process:

```
1: kd> .process
Implicit process is now 852b4040
1: kd> !process 852b4040 1
PROCESS 852b4040 SessionId: none Cid: 0004 Peb: 00000000 ParentCid: 0000
DirBase: 00185000 ObjectTable: 83203000 HandleCount: 663.
Image: System
...
...
```

In this case, the directory base is 0x00185000. Pass this address to **!ptov**:

```
1: kd> !ptov 185000
X86PtoV: pagedir 185000, PAE enabled.
15e11000 10000
549e6000 20000
...
60a000 210000
40b000 211000
...
54ad3000 25f000
548d3000 260000
...
d71000 77510000
...
```

The numbers in the left column are the physical addresses of each memory page that has a mapping for this process. The numbers in the right column are the virtual addresses to which they are mapped.

The total display is very long.

Here is a 64-bit example.

```
3: kd> .process
Implicit process is now ffffffa80`0361eb30
3: kd> !process ffffffa80`0361eb30 1
PROCESS ffffffa800361eb30
  SessionId: none  Cid: 0004  Peb: 00000000  ParentCid: 0000
  DirBase: 00187000  ObjectTable: fffff8a000002870  HandleCount: 919.
  Image: System
  ...
3: kd> !ptov 187000
Amd64PtoV: pagedir 187000

The directory base is the physical address of the first table that is used in virtual address translation. This table has different names depending on the bitness of the target operating system and whether Physical Address Extension (PAE) is enabled for the target operating system.

For 64-bit Windows, the directory base is the physical address of the Page Map Level 4 (PML4) table. For 32-bit Windows with PAE enabled, the directory base is the physical address of the Page Directory Pointers (PDP) table. For 32-bit Windows with PAE disabled, the directory bas is the physical address of the Page Directory (PD) table.

For related topics, see [!vtop](#) and [Converting Virtual Addresses to Physical Addresses](#). For information about virtual address translation, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

[Send comments about this topic to Microsoft](#)

!qlocks

5/31/2017 • 1 min to read • [Edit Online](#)

The **!qlocks** extension displays the state of all queued spin locks.

```
!qlocks
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about spin locks, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

This command is useful only on a multiprocessor system.

Here is an example:

```
0: kd> !qlocks
Key: 0 = Owner, 1-n = Wait order, blank = not owned/waiting, C = Corrupt

          Processor Number
Lock Name      0  1  2  3

KE  - Dispatcher
KE  - Unused Spare
MM  - PFN
MM  - System Space
CC  - Vacb
CC  - Master
EX  - NonPagedPool
IO  - Cancel
EX  - WorkQueue
IO  - Vpb
IO  - Database
IO  - Completion
NTFS - Struct
AFD  - WorkQueue
CC  - Bcb
MM  - MM NonPagedPool
```

[Send comments about this topic to Microsoft](#)

!ready

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ready** extension displays summary information about each thread in the system in a READY state.

```
!ready [Flags]
```

Parameters

Flags

Specifies the level of detail to display. *Flags* can be any combination of the following bits. If *Flags* is 0, only a minimal amount of information is displayed. The default is 0x6.

Bit 1 (0x2)

Causes the display to include the thread's wait states.

Bit 2 (0x4)

If this is included without Bit 1 (0x2), this has no effect. If this is included along with Bit 1, the thread is displayed with a stack trace.

Bit 3 (0x8)

(Windows XP and later) Causes the display of each function to include the return address, the stack pointer, and (on Itanium systems) the **bsp** register value. The display of function arguments is suppressed.

Bit 4 (0x10)

(Windows XP and later) Causes the display of each function to include only the return address; arguments and stack pointers are suppressed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about thread scheduling and the READY state, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

The output from this extension is similar to that of [!thread](#), except that only ready threads are displayed, and they are sorted in order of decreasing priority.

[Send comments about this topic to Microsoft](#)

!reg

5/31/2017 • 7 min to read • [Edit Online](#)

The **!reg** extension displays and searches through registry data.

```
!reg {querykey|q} FullKeyPath
!reg keyinfo HiveAddress KeyNodeAddress
!reg kcb Address
!reg knode Address
!reg kbody Address
!reg kvalue Address
!reg valuelist HiveAddress KeyNodeAddress
!reg subkeylist HiveAddress KeyNodeAddress
!reg baseblock HiveAddress
!reg seccache HiveAddress
!reg hashindex [HiveAddress]HashKey
!reg openkeys {HiveAddress|0}
!reg openhandles {HiveAddress|0}
!reg findkcb FullKeyPath
!reg hivelist
!reg viewlist HiveAddress
!reg freebins HiveAddress
!reg freecells BinAddress
!reg dirtyvector HiveAddress
!reg cellindex HiveAddress Index
!reg freehints HiveAddress Storage Display
!reg translist {RmAddress|0}
!reg uowlist TransactionAddress
!reg locktable KcbAddress ThreadAddress
!reg convkey KeyPath
!reg postblocklist
!reg notifylist
!reg ixlock LockAddress
!reg dumppool [s|r]
```

Parameters

{querykey|q} **** *FullKeyPath*

Displays subkeys and values of a key if the key is cached. *FullKeyPath* specifies the full key path.

keyinfo *HiveAddress* **** *KeyNodeAddress*

Displays subkeys and values of a key node. *HiveAddress* specifies the address of the hive. *KeyNodeAddress* specifies the address of the key node.

kcb **** *Address*

Displays a registry key control block. *Address* specifies the address of the key control block.

knode **** *Address*

Displays a registry key node structure. *Address* specifies the address of the key node.

kbody **** *Address*

Displays a registry key body structure. *Address* specifies the address of the key body. (Registry key bodies are the actual objects associated with handles.)

kvalue **** *Address*

Displays a registry key value structure. *Address* specifies the address of the value.

value **** *HiveAddress* **** *KeyNodeAddress*

Displays a list of the values in the specified key node. *HiveAddress* specifies the address of the hive.

KeyNodeAddress specifies the address of the key node.

subkey **** *HiveAddress* **** *KeyNodeAddress*

Displays a list of the subkeys of the specified key node. *HiveAddress* specifies the address of the hive.

KeyNodeAddress specifies the address of the key node.

baseblock **** *HiveAddress*

Displays the base block for a hive (also known as the *hive header*). *HiveAddress* specifies the address of the hive.

seccache **** *HiveAddress*

Displays the security cache for a hive. *HiveAddress* specifies the address of the hive.

hashindex **** [*HiveAddress*] **** *HashKey*

Computes the hash index entry for a hash key. *HiveAddress* specifies the address of the hive. *HashKey* specifies the key.

Note *HiveAddress* is required if the target computer is running Windows 7 or later.

openkeys {*HiveAddress*|0}

Displays all open keys in a hive. *HiveAddress* specifies the address of the hive. If zero is used instead, the entire registry hash table is displayed; this table contains all open keys in the registry.

findkcb **** *FullKeyPath*

Displays the registry key control block corresponding to a registry path. *FullKeyPath* specifies the full key path; this path must be present in the hash table.

hivelist

Displays a list of all hives in the system, along with detailed information about each hive.

viewlist **** *HiveAddress*

Displays all pinned and mapped views for a hive, with detailed information for each view. *HiveAddress* specifies the address of the hive.

freebins **** *HiveAddress*

Displays all free bins for a hive, with detailed information for each bin. *HiveAddress* specifies the address of the hive.

freecells **** *BinAddress*

Iterates through a bin and displays all free cells inside it. *BinAddress* specifies the address of the bin.

dirtyvector **** *HiveAddress*

Displays the dirty vector for a hive. *HiveAddress* specifies the address of the hive.

cellindex **** *HiveAddress* **** *Index*

Displays the virtual address for a cell in a hive. *HiveAddress* specifies the address of the hive. *Index* specifies the cell index.

freehints *HiveAddress* **** *Storage* **** *Display*

Displays free hint information.

translist {*RmAddress*|0}

Displays the list of active transactions in an RM. *RmAddress* specifies the address of the RM.

uowlist *TransactionAddress*

Displays the list of UoWs attached to a transaction. *TransactionAddress* specifies the address of the transaction.

locktable *KcbAddress* *ThreadAddress*

Displays relevant lock table content.

convkey *KeyPath*

Displays hash keys for a key path.

postblocklist

Displays the list of threads that have postblocks posted.

notifylist

Displays the list of notify blocks in the system.

ixlock *LockAddress*

Displays ownership of an intent lock. *LockAddress* specifies the address of the lock.

dumppool [**s|r**]

Displays registry-allocated paged pool. If **s** is specified, the list of registry pages is saved to a temporary file. If **r** is specified, the registry page list is restored from the previously saved temporary file.

DLL

Kdexts.dll

Additional Information

For information about the registry and its components, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

Here is an example. First use **!reg hivelist** to get a list of hive addresses.

```
00: kd> !reg hivelist
##

```

To display formatted registry key information, use the [!dreg](#) extension instead.

[Send comments about this topic to Microsoft](#)

!regkcb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!regkcb** extension displays a registry key control block.

```
!regkcb Address
```

Parameters

Address

Specifies the address of the key control block.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable

Additional Information

For information about the registry and its components, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

In Windows 2000, **!regkcb** displays a specific registry key control block.

In Windows XP and later versions of Windows, the [!reg](#) extension command should be used instead.

Every registry key has a control block that contains properties, such as its permissions.

[Send comments about this topic to Microsoft](#)

!rellist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rellist** extension displays a Plug and Play relation list.

```
!rellist Address [Flags]
```

Parameters

Address

Specifies the address of the relation list.

Flags

Specifies additional information to include in the display. This can be any combination of the following bits (the default is zero):

Bit 1 (0x2)

Causes the display to include the CM_RESOURCE_LIST. The display also includes the boot resources list, if it is available.

Bit 2 (0x4)

Causes the display to include the resource requirements list (IO_RESOURCE_LIST).

Bit 3 (0x8)

Causes the display to include the translated CM_RESOURCE_LIST.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about these list structures, see the Windows Driver Kit (WDK) documentation.

[Send comments about this topic to Microsoft](#)

!ruleinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ruleinfo** command displays information about a Driver Verifier rule.

```
!ruleinfo RuleId [RuleState [SubState]]
```

Parameters

RuleId

The ID of the verifier rule. This is the first argument of the **DRIVER_VERIFIER_DETECTED_VIOLATION** bug check.

RuleState

Additional state information about the violation. This is the third argument of the **DRIVER_VERIFIER_DETECTED_VIOLATION** bug check.

SubState

Sub-state information about the violation. This is the fourth argument of the **DRIVER_VERIFIER_DETECTED_VIOLATION** bug check.

DLL

ext.dll

Remarks

This command applies only to rules in the Driver Verifier extension; that is, rules that have an ID greater than or equal to 0x10000.

The following example shows the four arguments of a **DRIVER_VERIFIER_DETECTED_VIOLATION** bug check.

```

DRIVER_VERIFIER_DETECTED_VIOLATION (c4)
...
Arguments:
Arg1: 000000000091001, ID of the 'NdisOidComplete' rule that was violated.
Arg2: fffff800002d49d0, A pointer to the string describing the violated rule condition.
Arg3: fffffe000027b8370, Address of internal rule state (second argument to !ruleinfo).
Arg4: fffffe000027b83f8, Address of supplemental states (third argument to !ruleinfo).

## Debugging Details:

DV_VIOLATED_CONDITION: This OID should only be completed with NDIS_STATUS_NOT_ACCEPTED,
                        NDIS_STATUS_SUCCESS, or NDIS_STATUS_PENDING.

DV_MSDN_LINK: http://go.microsoft.com/fwlink/?linkid=278802

DRIVER_OBJECT: fffffe0000277a2b0
...
STACK_TEXT:
fffffd000`2118ff58 fffff803`4c83afa2 : 00000000`000000c4 00000000`00000001 ...
fffffd000`2118ff60 fffff803`4c83a8c0 : 00000000`00000003 00000000`00091001 ...
...
STACK_COMMAND: kb

FOLLOWUP_NAME: XXXX

FAILURE_BUCKET_ID: XXXX
...

```

In the preceding output, the rule ID (0x91001) is shown as Arg1. Arg3 and Arg4 are the addresses of rule state and substate information. You can pass the rule ID, the rule state, and the substate to **!ruleinfo** to get a description of the rule and a link to detailed documentation of the rule.

```

3: kd> !ruleinfo 0x91001 0xfffffe000027b8370 0xfffffe000027b83f8

RULE_ID: 0x91001

RULE_NAME: NdisOidComplete

RULE_DESCRIPTION:
This rule verifies if an NDIS miniport driver completes an OID correctly.
Check RULE_STATE for Oid ( use !ndiskd.oid ), which can be one of the following:
1) NULL,
2) Pending OID, or
3) Previous OID if no OID is pending.

MSDN_LINK: http://go.microsoft.com/fwlink/?linkid=278802

CONTEXT: Miniport 0xFFFFE0000283F1A0

CURRENT_TIME (Timed Rules): 142 seconds

RULE_STATE: 0xFFFFE000027B83F8

```

[Send comments about this topic to Microsoft](#)

!running

5/31/2017 • 1 min to read • [Edit Online](#)

The **!running** extension displays a list of running threads on all processors of the target computer.

```
!running [-i] [-t]
```

Parameters

-i

Causes the display to include idle processors as well.

-t

Causes a stack trace to be displayed for each processor.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For more information about debugging multiprocessor computers, see [Multiprocessor Syntax](#).

Remarks

With no options, **!running** will display the affinity of all active processors and all idle processors. For all active processors, it will also display the current and next thread fields from the process control block (PRCB) and the state of the 16 built-in queued spin locks.

Here is an example from a multiprocessor Itanium system:

```
0: kd> !running

System Processors 3 (affinity mask)
Idle Processors 0

      Prcb          Current          Next
  0  e0000000818f8000  e0000000818f9e50  e0000000866f12f0  .....
  1  e000000086f16010  e00000008620ebe0  e000000086eddbc0  .0.....
```

The 16 characters at the end of each line indicate the built-in queued spin locks (the LockQueue entries in the PRCB). A period (.) indicates that the lock is not in use, **O** means the lock is owned by this processor, and **W** means the processor is queued for the lock. To see more information about the spin lock queue, use [!qlocks](#).

Here is an example that shows active and idle processors, along with their stack traces:

```
0: kd> !running -it

System Processors f (affinity mask)
  Idle Processors f
All processors idle.

      Prcb      Current      Next
0  ffdff120  805495a0  .....
ChildEBP RetAddr
8053e3f0 805329c2 nt!RtlpBreakWithStatusInstruction
8053e3f0 80533464 nt!_KeUpdateSystemTime+0x126
ffdff980 ffdff980 nt!KiIdleLoop+0x14

1  f87e0120  f87e2e60  .....
ChildEBP RetAddr

2  f87f0120  f87f2e60  .....
ChildEBP RetAddr
f87f0980 f87f0980 nt!KiIdleLoop+0x14

3  f8800120  f8802e60  .....
ChildEBP RetAddr
f8800980 f8800980 nt!KiIdleLoop+0x14
```

[Send comments about this topic to Microsoft](#)

!scm

5/31/2017 • 1 min to read • [Edit Online](#)

The **!scm** extension displays the specified shared cache map.

```
!scm Address
```

Parameters

Address

Specifies the address of the shared cache map.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable

Additional Information

For information about cache management, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

For information about other cache management extensions, see the [!icchelp](#) extension.

Remarks

In Windows XP and later versions of Windows, use the [dt nt!_SHARED_CACHE_MAP Address](#) command instead of **!scm**.

[Send comments about this topic to Microsoft](#)

!search

5/31/2017 • 3 min to read • [Edit Online](#)

The **!search** extension searches pages in physical memory for pointer-sized data that matches the specified criteria.

Syntax

```
!search [-s] [-p] Data [ Delta [ StartPFN [ EndPFN ]]]  
!search -?
```

Parameters

-s

Causes symbol check errors to be ignored during the search. This is useful if you are getting too many "incorrect symbols for kernel" errors.

-p

Causes the value of *Data* to be interpreted as a 32-bit value, preventing any sign extension.

Data

Specifies the data to search for. *Data* must be the size of a pointer on the target system (32 bits or 64 bits). An exact match for the value of *Data* is always displayed. Other matches are displayed as well, depending on the value of *Delta*; see the Remarks section below for details.

Delta

Specifies the allowable difference between a value in memory and the value of *Data*. See the Remarks section below for details.

StartPFN

Specifies the page frame number (PFN) of the beginning of the range to be searched. If this is omitted, the search begins at the lowest physical page.

EndPFN

Specifies the page frame number (PFN) of the end of the range to be searched. If this is omitted, the search ends at the highest physical page.

-?

Displays help for this extension in the Debugger Command window.

DLL

Kdexts.dll

Additional Information

For more ways to display and search physical memory, see [Reading and Writing Memory](#).

Remarks

If *StartPFN* and *EndPFN* are specified, these are taken as the page frame numbers of the beginning and end of the range in physical memory to be searched. For an explanation of page frame numbers, see [Converting Virtual Addresses to Physical Addresses](#). If *StartPFN* and *EndPFN* are omitted, all physical memory is searched.

All hits are displayed.

The **!search** extension will search through all memory for in the specified page range and examine each ULONG_PTR-aligned value. Values that satisfy at least one of the following criteria are displayed:

- The value matches *Data* exactly.
- If Delta is 0 or omitted: The value differs from *Data* by a single bit.
- If Delta is nonzero: The value differs from *Data* by at most *Delta*. In other words, the value lies in the range [Data - Delta, Data + Delta].
- If Delta is nonzero: The value differs from the lowest number in the range (Data - Delta) by a single bit.

In most cases, *Data* will specify an address you are interested in, but any ULONG_PTR sized data can be specified.

Because the debugger's search engine structures reside in memory on the target computer, if you search all of memory (or any range containing these structures) you will see matches in the area where the structures themselves are located. If you need to eliminate these matches, do a search for a random value; this will indicate where the debugger's search structures are located.

Here are some examples. The following will search the memory page with PFN 0x237D for values between 0x80001230 and 0x80001238, inclusive:

```
kd> !search 80001234 4 237d 237d
```

The following will search the memory pages ranging from PFN 0x2370 to 0x237F for values that are within one bit of 0x0F100F0F. The exact matches are indicated in bold; the others are off by one bit:

```
kd> !search 0f100f0f 0 2370 237f
Searching PFNs in range 00002370 - 0000237F for [0F100F0F - 0F100F0F]

Pfn      Offset     Hit      Va      Pte
----- 
0000237B 00000368 0F000F0F 01003368 C0004014
0000237C 00000100 0F100F0F 01004100 C0004014
0000237D 000003A8 0F100F0F 010053A8 C0004014
0000237D 000003C8 0F100F8F 010053C8 C0004014
0000237D 000003E8 0F100F0F 010053E8 C0004014
0000237D 00000408 0F100F0F 01005408 C0004014
0000237D 00000428 0F100F8F 01005428 C0004014
Search done.
```

The columns in the display are as follows: **Pfn** is the page frame number (PFN) of the page; **Offset** is the offset on that page; **Hit** is the value at that address; **Va** is the virtual address mapped to this physical address (if this exists and can be determined); **Pte** is the page table entry (PTE).

To calculate the physical address, shift the PFN left three hexadecimal digits (12 bits) and add the offset. For example, the last line in the table is virtual address 0x0237D000 + 0x428 = 0x02347D428.

[Send comments about this topic to Microsoft](#)

!searchpte

5/31/2017 • 1 min to read • [Edit Online](#)

The **!searchpte** extension searches physical memory for the specified page frame number (PFN).

```
!searchpte PFN
!searchpte -?
```

Parameters

PFN

Specifies the PFN in hexadecimal format.

-?

Displays help for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about page tables and page directories, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

To stop execution at any time, press CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!sel

5/26/2017 • 1 min to read • [Edit Online](#)

The **!sel** extension command is obsolete. Use the [dg \(Display Selector\)](#) command instead.

[Send comments about this topic to Microsoft](#)

!session

5/31/2017 • 1 min to read • [Edit Online](#)

The **!session** extension controls the session context. It can also display a list of all user sessions.

Syntax

```
!session
!session -s DefaultSession
!session -?
```

Parameters

-s ** DefaultSession**

Sets the [session context](#) to the specified value. If *DefaultSession* is -1, the session context is set to the current session.

-?

Displays help for this extension in the Debugger Command window.

DLL

Kdexts.dll

Additional Information

For information about user sessions and the Session Manager (smss.exe), see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

The **!session** extension is used to control the session context. Using **!session** with no parameters will display a list of active sessions on the target computer. Using **!session /s DefaultSession** will change the session context to the new default value.

When you set the session context, the process context is automatically changed to the active process for that session, and the [.cache forcedecodeptes](#) option is enabled so that session addresses are translated properly.

For more details and a list of all the session-related extensions that are affected by the session context, see [Changing Contexts](#).

[Send comments about this topic to Microsoft](#)

!smt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!smt** extension displays a summary of the simultaneous multithreaded processor information.

```
!smt
```

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

Here is an example:

```
1kd> !smt
SMT Summary:
-----
KeActiveProcessors: **----- (00000003)
KiIdleSummary: ----- (00000000)
No PRCB      Set Master SMT Set          IAID
0 820f4820  Master    **----- (00000003)  00
1 87a4d120  820f4820  **----- (00000003)  01

Maximum cores per physical processor: 2
Maximum logical processors per core:  1
```

The **No** column indicates the number of the processor.

The **PRCB** column indicates the address of the processor control block for the processor. Each logical processor is listed separately.

Each physical processor has exactly one logical processor listed as the **Master** under the **Set Master** column.

The **SMT Set** column lists the processor's simultaneous multithreaded processor set information.

The **IAID** column lists the initial Advanced Programmable Interrupt Controller identifier (APIC ID). On a true x64 computer, each processor starts with a hard-coded initial APIC ID. This ID value can be retrieved through the CPUID instruction. On certain other computers, the initial APIC ID is not necessarily unique across all processors, so the APIC ID that is accessible through the APIC's memory-mapped input/output (MMIO) space can be modified. This technique enables software to allocate unique APIC IDs for all processors within the computer. Depending on the target computer's processors, the **IAID** column may show this ID or may be blank.

[Send comments about this topic to Microsoft](#)

!sprocess

5/31/2017 • 1 min to read • [Edit Online](#)

The **!sprocess** extension displays information about the specified session process, or about all processes in the specified session.

```
!sprocess Session [Flags [ImageName]]  
!sprocess -?
```

Parameters

Session

Specifies the session that owns the desired process. *Session* is always interpreted as a decimal number.

Session can have the following values:

-1	Use current session. This is the default.
-2	Use session context .
-4	Display all processes by session.

Flags

Specifies the level of detail in the display. *Flags* can be any combination of the following bits. The default is 0.

0x0	Display minimal information.
Bit 0 (0x1)	Display time and priority statistics.
Bit 1 (0x2)	Adds to the display a list of threads and events associated with the process and the wait states of the threads.
Bit 2 (0x4)	Adds to the display a list of threads associated with the process. If this bit is used without Bit 1 (0x2), each thread is displayed on a single line. If this is included with Bit 1, each thread is displayed with a stack trace.
Bit 3 (0x8)	Adds to the display of each function the return address, the stack pointer and, on Itanium-based systems, the bsp register value. It suppresses the display of function arguments.
Bit 4 (0x10)	Display only the return address of each function. Suppress the arguments and stack pointers.

ImageName

Specifies the name of the process to be displayed. All processes whose executable image names match *ImageName* are displayed. The image name must match that in the EPROCESS block. In general, this is the executable name that was invoked to start the process, including the file extension (usually .exe), and truncated after the fifteenth character. There is no way to specify an image name that contains a space.

-?

Displays help for this extension in the Debugger Command window. This help text has some omissions.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about sessions and processes in kernel mode, see [Changing Contexts](#). For more information about analyzing processes and threads, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

The output of this extension is similar to that of [!process](#), except that the addresses of _MM_SESSION_SPACE and _MMSESSION are displayed as well.

[Send comments about this topic to Microsoft](#)

!srb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!srb** extension displays information about a SCSI Request Block (SRB).

```
!srb Address
```

Parameters

Address

Specifies the hexadecimal address of the SRB on the target computer.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about SRBs, see the Windows Driver Kit (WDK) documentation.

Remarks

An SRB is a system-defined structure used to communicate I/O requests from a SCSI class driver to a SCSI port driver.

[Send comments about this topic to Microsoft](#)

!stacks

5/31/2017 • 1 min to read • [Edit Online](#)

The **!stacks** extension displays information about the kernel stacks.

Syntax

```
!stacks [Detail [FilterString]]
```

Parameters

Detail

Specifies the level of detail to use in the display. The following table lists the valid values for *Detail*.

0	Displays a summary of the current kernel stacks. This is the default value.
1	Displays stacks that are currently paged out, as well as the current kernel stacks.
2	Displays the full parameters for all stacks, as well as stacks that are currently paged out and the current kernel stacks.

FilterString

Displays only threads that contain the specified substring in a symbol.

DLL

Kdexts.dll

Additional Information

For information about kernel stacks, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

The **!stacks** extension gives a brief summary of the state of every thread. You can use this extension instead of the **!process** extension to get a quick overview of the system, especially when debugging multithread issues such as resource conflicts or deadlocks.

The **!findstack** user-mode extension also displays information about particular stacks.

Here is an example of the simplest **!stacks** display:

```

kd> !stacks 0
Proc.Thread .Thread ThreadState Blocker
          [System]
4.000050 827eea10 Blocked    +0xfe0343a5

          [smss.exe]

          [csrss.exe]
b0.0000a8 82723b70 Blocked    ntoskrnl!_KiSystemService+0xc4
b0.0000c8 82719620 Blocked    ntoskrnl!_KiSystemService+0xc4
b0.0000d0 827d5d50 Blocked    ntoskrnl!_KiSystemService+0xc4
.....

```

The first column shows the process ID and the thread ID (separated by a period).

The second column is the current address of the thread's ETHREAD block.

The third column shows the state of the thread (initialized, ready, running, standby, terminated, transition, or blocked).

The fourth column shows the top address on the thread's stack.

Here are examples of more detailed **!stacks** output:

```

kd> !stacks 1
Proc.Thread .Thread ThreadState Blocker
          [System]
4.000008 827d0030 Blocked    ntoskrnl!MmZeroPageThread+0x66

                               ntoskrnl!KeWaitForMultipleObjects+0x2b4
                               ntoskrnl!MmZeroPageThread+0x66
                               ntoskrnl!Phase1Initialization+0xd82
                               ntoskrnl!PspSystemThreadStartup+0x4d
                               ntoskrnl!CreateSystemRootLink+0x3d8
                               +0x3f3f3f3f
4.000010 827d0430 Blocked    ntoskrnl!KiSwapThread+0xc5
                               ntoskrnl!KeRemoveQueue+0x191
.....

```

[Send comments about this topic to Microsoft](#)

!swd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!swd** extension displays the software watchdog timer states for the specified processor, including the deferred procedure call (DPC) and the watchdog timer states for threads.

```
!swd [Processor]
```

Parameters

Processor

Specifies the processor. If *Processor* is omitted, information is displayed for all processors on the target computer.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

The watchdog timer shuts down or restarts Windows if Windows stops responding. The times are displayed in seconds.

[Send comments about this topic to Microsoft](#)

!sysinfo

5/31/2017 • 2 min to read • [Edit Online](#)

The **!sysinfo** extension reads and displays specified SMBIOS, Advanced Configuration and Power Interface (ACPI), and CPU information from a dump file or live system.

```
!sysinfo cpuinfo [-csv [-noheaders]]  
!sysinfo cpumicrocode [-csv [-noheaders]]  
!sysinfo cpuspeed [-csv [-noheaders]]  
!sysinfo gbl [-csv [-noheaders]]  
!sysinfo machineid [-csv [-noheaders]]  
!sysinfo registers  
!sysinfo smbios [-csv [-noheaders]] {-debug | -devices | -memory | -power | -processor | -system | -v}  
!sysinfo -?
```

Parameters

cpuinfo

Displays information about the processor.

cpumicrocode

(GenuineIntel processors only) Displays the initial and cached microcode processor versions.

cpuspeed

Displays the maximum and current processor speeds.

gbl

Displays the BIOS list of ACPI tables.

machineid

Displays machine ID information for the SMBIOS, BIOS, firmware, system, and baseboard.

registers

Displays machine-specific registers (MSRs).

smbios

Displays the SMBIOS table.

-csv

Displays all data in comma-separated, variable-length (CSV) format.

-noheaders

Suppresses the header for the CSV format.

-debug

Displays output in standard format and CSV format.

-devices

Displays the device entries in the SMBIOS table.

-memory

Displays the memory entries in the SMBIOS table.

-power

Displays the power entries in the SMBIOS table.

-processor

Displays the processor entries in the SMBIOS table.

-system

Displays the system entries in the SMBIOS table.

-v

Verbose. Displays the details of entries in the SMBIOS table.

-?

Displays help for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP base system	Unavailable
Windows 2003 base system	
Windows XP, Service Pack 2 and later	Kdexts.dll
Windows 2003, Service Pack 1 and later	

Remarks

This extension is useful only when the dump file is a System Crash File (.dmp) that has not been converted to a minidump file from a kernel or full dump file, or the live system has finished starting and is online (for example, at the log-in prompt).

You can use any combination of the **-debug**, **-devices**, **-memory**, **-power**, **-processor**, **-system**, and **-v** parameters in a single extension command.

The following parameters are supported only on particular systems:

- The **gbl** parameter works only when the target computer supports ACPI.
- The **smbios** parameter works only when the target computer supports SMBIOS.
- The **registers** parameter does not work on Itanium-based target computers, because they do not collect MSRs.

Microsoft makes every effort to remove personally identifiable information (PII) from these records. All PII is removed from dump files. However, on a live system, some PII may not yet be removed. As a result, PII fields will be reported as 0 or blank, even if they actually contain information.

To stop execution of commands that include the **cpuinfo**, **gbl**, **registers**, or **smbios** parameters at any time, press CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!sysptes

5/31/2017 • 2 min to read • [Edit Online](#)

The **!sysptes** extension displays a formatted view of the system page table entries (PTEs).

```
!sysptes [Flags]
```

Parameters

Flags

Specifies the level of detail to display. *Flags* can be any combination of the following bits. The default is zero:

Bit 0 (0x1)

Displays information about free PTEs.

Bit 1 (0x2)

(Windows 2000 only) Displays unused pages in the page usage statistics.

(Windows XP and later) Displays information about free PTEs in the global special pool.

Bit 2 (0x4)

Displays detailed information about any system PTEs that are allocated to mapping locked pages.

Bit 3 (0x8)

(Windows 2000 and Windows XP only) Displays nonpaged pool expansion free PTE information. If this bit is set, the other lists are not displayed. If both 0x1 and 0x8 are set, all nonpaged pool expansion free PTEs are displayed. If only 0x8 is set, only the total is displayed.

Bit 4 (0x10)

(Windows Vista and later) Displays special pool free PTE information for the session.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about page tables and PTEs, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

To examine a specific PTE, use the [!pte](#) extension.

Here is an example from a Windows 2000 system:

```
kd> !sysptes 1

System PTE Information
Total System Ptes 50962
  SysPtes list of size 1 has 389 free
  SysPtes list of size 2 has 95 free
  SysPtes list of size 4 has 55 free
  SysPtes list of size 8 has 35 free
  SysPtes list of size 16 has 27 free

  starting PTE: c03c7000
  ending PTE:   c03f8c44

  loading (99% complete)

  free ptes: c03c8d60  number free: 45134.

  free blocks: 1  total free: 45134  largest free block: 45134

  Page  Count
  a0      2.
  a1      2.
  a2      2.
  a3      2.

  .....
```

In Windows XP and later versions of Windows, the display is similar, except that the page count statistics at the end are not included. Here is an example from a Windows XP system:

```
kd> !sysptes 1

System PTE Information
Total System Ptes 571224
  SysPtes list of size 1 has 361 free
  SysPtes list of size 2 has 91 free
  SysPtes list of size 4 has 48 free
  SysPtes list of size 8 has 36 free
  SysPtes list of size 9 has 29 free
  SysPtes list of size 23 has 29 free

  starting PTE: fffffe0059388000
  ending PTE:   fffffe00597e3ab8

  free ptes: fffffe0059388000  number free: 551557.
  free ptes: fffffe00597be558  number free: 104.
  free ptes: fffffe00597d2828  number free: 676.

  free blocks: 3  total free: 552337  largest free block: 551557
```

[Send comments about this topic to Microsoft](#)

!thread

5/31/2017 • 3 min to read • [Edit Online](#)

The **!thread** extension displays summary information about a thread on the target system, including the ETHREAD block. This command can be used only during kernel-mode debugging.

This extension command is not the same as the [.thread \(Set Register Context\)](#) command.

Syntax

```
!thread [-p] [-t] [Address [Flags]]
```

Parameters

-p

Displays summary information about the process that owns the thread.

-t

When this option is included, *Address* is the thread ID, not the thread address.

Address

Specifies the hexadecimal address of the thread on the target computer. If *Address* is -1 or omitted, it indicates the current thread.

Flags

Specifies the level of detail to display. *Flags* can be any combination of the following bits. If *Flags* is 0, only a minimal amount of information is displayed. The default is 0x6:

Bit 1 (0x2)

Displays the thread's wait states.

Bit 2 (0x4)

If this bit is used without Bit 1 (0x2), it has no effect. If this bit is used with Bit 1, the thread is displayed with a stack trace.

Bit 3 (0x8)

Adds the return address, the stack pointer, and (on Itanium systems) the **bsp** register value to the information displayed for each function and suppresses the display of function arguments.

Bit 4 (0x10)

Sets the process context equal to the process that owns the specified thread for the duration of this command. This results in more accurate display of thread stacks.

DLL

Kdexts.dll

Additional Information

For information about threads in kernel mode, see [Changing Contexts](#). For more information about analyzing processes and threads, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

Here is an example using Windows 10:

```
0: kd> !thread 0xffffcb088f0a4480
THREAD fffffcb088f0a4480  Cid 0e34.3814  Teb: 0000001a27ca6000 Win32Thread: 0000000000000000 RUNNING on

Use commands like **!process** to locate the address or thread ID of the thread you are interested in.

The useful information in the **!thread** display is explained in the following table.

PARAMETER	MEANING
Thread address	The hexadecimal number after the word <i>THREAD</i> is the address of the ETHREAD block. In the preceding example, the thread address is 0xffffcb088f0a4480 .
Thread ID	The two hexadecimal numbers after the word <i>Cid</i> are the process ID and the thread ID: <i>process ID.thread ID</i> . In the preceding example, the process ID is 0x0e34, and the thread ID is 0x3814.
Thread Environment Block (TEB)	The hexadecimal number after the word <i>Teb</i> is the address of the thread environment block (TEB).
System Service Dispatch Table	The hexadecimal number after the word <i>Win32Thread</i> is the address of the system service dispatch table.
Thread State	The thread state is displayed at the end of the line that begins with the word <i>RUNNING</i> .
Owning Process	The hexadecimal number after the words <i>Owning Process</i> is the address of the EPROCESS for the process that owns this thread.

PARAMETER	MEANING
Start Address	The hexadecimal number after the words <i>Start Address</i> is the thread start address. This might appear in symbolic form.
User Thread Function	The hexadecimal number after the words <i>Win32 Start Address</i> is the address of the user thread function.
Priority	The priority information for the thread follows the word <i>Priority</i> .
Stack trace	A stack trace for the thread appears at the end of this display.

!threadfields

5/31/2017 • 1 min to read • [Edit Online](#)

The **!threadfields** extension displays the names and offsets of the fields within the executive thread (ETHREAD) block.

```
!threadfields
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable (see the Remarks section)

Additional Information

For information about the ETHREAD block, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

This extension command is not available in Windows XP or later versions of Windows. Instead, use the [dt \(Display Type\)](#) command to show the ETHREAD structure directly:

```
kd> dt nt!_ETHREAD
```

Here is an example of **!threadfields** from a Windows 2000 system:

```
kd> !threadfields
ETHREAD structure offsets:

!time

5/26/2017 • 1 min to read • [Edit Online](#)

The **!time** extension command is obsolete. Use the [.time \(Display System Time\)](#) command instead.

[Send comments about this topic to Microsoft](#)

!timer

5/31/2017 • 1 min to read • [Edit Online](#)

The **!timer** extension displays a detailed listing of all system timer use.

```
!timer
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about timer objects, see the Windows Driver Kit (WDK) documentation.

Remarks

The **!timer** extension displays the timer tree, which stores all timer objects in the system.

Here is an example:

```
kd> !timer
Dump system timers

Interrupt time: 9f760774 00000000 [12/ 8/2000 10:59:22.685 (Pacific Standard Time)]

[Send comments about this topic to Microsoft](#)

!tokenfields

5/31/2017 • 1 min to read • [Edit Online](#)

The **!tokenfields** extension displays the names and offsets of the fields within the access token object (the TOKEN structure).

```
!tokenfields
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable (see the Remarks section)

Additional Information

For information about the TOKEN structure, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. This book may not be available in some languages and countries.(The user-mode token structures described in the Microsoft Windows SDK documentation are slightly different.)

Remarks

This extension command is not available in Windows XP or later versions of Windows. Instead, use the [dt \(Display Type\)](#) command to show the TOKEN structure directly:

```
kd> dt nt!_TOKEN
```

To see a specific instance of the TOKEN structure, use the [!token](#) extension.

Here is an example of **!tokenfields** from a Windows 2000 system:

```
kd> !tokenfields
TOKEN structure offsets:
TokenSource:          0x0
AuthenticationId:    0x18

The **!tss** extension command is obsolete. Use the [.tss \(Display Task State Segment\)](#) command instead.

[Send comments about this topic to Microsoft](#)

!tz

5/31/2017 • 1 min to read • [Edit Online](#)

The **!tz** extension displays the specified power thermal zone structure.

```
!tz [Address]
```

Parameters

Address

The address of a power thermal zone that you want to display. If this parameter is omitted, the display includes all thermal zones on the target computer.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

To view the system's power capabilities, use the **!pocaps** extension command. To view the system's power policy, use the **!popolicy** extension command. For information about power capabilities and power policy, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

To stop execution at any time, press CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!tzinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!tzinfo** extension displays the contents of the specified thermal zone information structure.

```
!tzinfo Address
```

Parameters

Address

The address of a thermal zone information structure that you want to display.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

To view the system's power capabilities, use the **!pocaps** extension command. To view the system's power policy, use the **!popolicy** extension command. For information about power capabilities and power policy, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

!ubc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ubc** extension clears a user-space breakpoint.

```
!ubc BreakpointNumber
```

Parameters

BreakpointNumber

Specifies the number of the breakpoint to be cleared. An asterisk (*) indicates all breakpoints.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

This will permanently delete a breakpoint set with **!ubp**.

!ubd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ubd** extension temporarily disables a user-space breakpoint.

```
!ubd BreakpointNumber
```

Parameters

BreakpointNumber

Specifies the number of the breakpoint to be disabled. An asterisk (*) indicates all breakpoints.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

Disabled breakpoints will be ignored. Use **!ube** to re-enable the breakpoint.

[User Space and System Space](#)

[Send comments about this topic to Microsoft](#)

!ube

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ube** extension re-enables a user-space breakpoint.

```
!ube BreakpointNumber
```

Parameters

BreakpointNumber

Specifies the number of the breakpoint to be enabled. An asterisk (*) indicates all breakpoints.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

This is used to re-enable a breakpoint that was disabled by **!ubd**.

See also

[!ubc](#)

[!ubd](#)

[!ubl](#)

[!ubp](#)

[User Space and System Space](#)

[Send comments about this topic to Microsoft](#)

!ubl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ubl** extension lists all user-space breakpoints and their current status.

```
!ubl
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

Here is an example of the use and display of user-space breakpoints:

```
kd> !ubp 8014a131
This command is VERY DANGEROUS, and may crash your system!
If you don't know what you are doing, enter "!ubc *" now!

kd> !ubp 801544f4

kd> !ubd 1

kd> !ubl
0: e ffffffff`8014a131 (fffffff`82deb000) 1 ffffffff
1: d ffffffff`801544f4 (fffffff`82dff000) 0 ffffffff
```

Each line in this listing contains the breakpoint number, the status (**e** for enabled or **d** for disabled), the virtual address used to set the breakpoint, the physical address of the actual breakpoint, the byte position, and the contents of this memory location at the time the breakpoint was set.

[!ubp](#)

[User Space and System Space](#)

[Send comments about this topic to Microsoft](#)

!ubp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ubp** extension sets a breakpoint in user space.

```
!ubp Address
```

Parameters

Address

Specifies the hexadecimal virtual address of the location in user space where the breakpoint is to be set.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

The **!ubp** extension sets a breakpoint in user space. The breakpoint is set on the actual physical page, not just the virtual page.

Setting a physical breakpoint will simultaneously modify every virtual copy of a page, with unpredictable results. One possible consequence is corruption of the system state, possibly followed by a bug check or other system crash. Therefore, these breakpoints should be used cautiously, if at all.

This extension cannot be used to set breakpoints on pages that have been swapped out of memory. If a page is swapped out of memory after a breakpoint is set, the breakpoint ceases to exist.

It is not possible to set a breakpoint inside a page table or a page directory.

Each breakpoint is assigned a *breakpoint number*. To find out the breakpoint number assigned, use **!ubl**.

Breakpoints are enabled upon creation. To step over a breakpoint, you must first disable it by using **!ubd**. To clear a breakpoint, use **!ubc**.

!urb

5/26/2017 • 1 min to read • [Edit Online](#)

The **!urb** extension command is obsolete. Use the **dt URB** command instead.

[Send comments about this topic to Microsoft](#)

!vad

5/31/2017 • 1 min to read • [Edit Online](#)

The **!vad** extension displays details of a virtual address descriptor (VAD) or a tree of VADs.

- Displays details of one virtual address descriptor (VAD)
- Displays details of a tree of VADs.
- Displays information about the VADs for a particular user-mode module and provides a string that you can use to load the symbols for that module.

```
!vad VAD-Root [Flag]  
!vad Address 1
```

Parameters

VAD-Root

Address of the root of the VAD tree to be displayed.

Flag

Specifies the form the display will take. Possible values include:

0

The entire VAD tree based at *VAD-Root* is displayed. (This is the default.)

1

Only the VAD specified by *VAD-Root* is displayed. The display will include a more detailed analysis.

Address

Address in the virtual address range of a user-mode module.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about virtual address descriptors, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

The address of the root of the VAD for any process can be found by using the [!process](#) command.

The **!vad** command can be helpful when you need to load symbols for a user-mode module that has been paged out of memory. For details, see [Mapping Symbols When the PEB is Paged Out](#).

Here is an example of the **!vad** extension:

```
kd> !vad 824bc2f8
VAD      level      start      end      commit
82741bf8 ( 1)    78000    78045      8 Mapped  Exe  EXECUTE_WRITECOPY

!vad_reload

5/31/2017 • 1 min to read • [Edit Online](#)

The **!vad_reload** extension reloads the user-mode modules for a specified process by using the virtual address descriptors (VADs) of that process.

```
!vad_reload Process
```

Parameters

Process

Specifies the hexadecimal address of the process for which the modules will be loaded.

Additional Information

For information about VADs, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

You can use the [!process](#) extension to find the address of a process.

Here is an example of how to find an address and use it in the **!vad_reload** command.

```
3: kd> !process 0 0
...
PROCESS ffffffa8007d54450
  SessionId: 1 Cid: 115c Peb: 7fffffef6000 ParentCid: 0c58

!validateclist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!validateclist** extension verifies that the backward and forward links in a doubly-linked list are valid.

```
!validateclist Address
```

Parameters

Address

The address of the doubly-linked list.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

To stop execution, press Ctrl+Break (in WinDbg) or Ctrl+C (in KD).

[Send comments about this topic to Microsoft](#)

!verifier

5/31/2017 • 8 min to read • [Edit Online](#)

The **!verifier** extension displays the status of Driver Verifier and its actions.

Driver Verifier is included in Windows. It works on both checked and free builds. For information about Driver Verifier, see the [Driver Verifier](#) topic in the Windows Driver Kit (WDK) documentation.

Syntax

```
!verifier [Flags [Image]]
!verifier 4 [Quantity]
!verifier 8 [Quantity]
!verifier 0x40 [Quantity]
!verifier 0x80 [Quantity]
!verifier 0x80 Address
!verifier 0x100 [Quantity]
!verifier 0x100 Address
!verifier 0x200 [Address]
!verifier 0x400 [Address]
!verifier -disable
!verifier ?
```

Parameters

Flags

Specifies what information is displayed in the output from this command. If *Flags* is equal to the value 4, 8, 0x20, 0x40, 0x80, or 0x100, then the remaining arguments to **!verifier** are interpreted based on the specific arguments associated with those values. If *Flags* is equal to any other value, even if one or more of these bits are set, only the *Flags* and *Image* arguments are permitted. *Flags* can be any sum of the following bits; the default is 0:

Bit 0 (0x1)

Displays the names of all drivers being verified. The number of bytes currently allocated to each driver from the nonpaged pool and the paged pool is also displayed.

Bit 1 (0x2)

Displays information about pools (pool size, headers, and pool tags) and outstanding memory allocations left by unloaded drivers. This flag has no effect unless bit 0 (0x1) is also set.

Bit 2 (0x4)

(Windows XP and later) Displays fault injection information. The return address, symbol name, and displacement of the code requesting each allocation are displayed. If *Flags* is exactly 0x4 and the *Quantity* parameter is included, the number of these records displayed can be chosen. Otherwise, four records are displayed.

Bit 3 (0x8)

(Windows XP and later) Displays the most recent IRQL changes made by the drivers being verified. The old IRQL, new IRQL, processor, and time stamp are displayed. If *Flags* is exactly 0x8 and the *Quantity* parameter is included, the number of these records displayed can be chosen. Otherwise, four records are displayed.

Warning In 64-bit versions of Windows, some of the kernel functions that raise or lower the IRQL are implemented as inline code rather than as exported functions. Driver Verifier does not report IRQL changes made by inline code, so it is possible for the IRQL transition log produced by Driver Verifier to be incomplete. See Remarks for an example of a missing IRQL transition entry.

Bit 6 (0x40)

(Windows Vista and later) Displays information from the **Force Pending I/O Requests** option of Driver Verifier, including traces from the log of forced pending IRPs.

The *Quantity* parameter specifies the number of traces to be displayed. By default, the entire log is displayed.

Bit 7 (0x80)

(Windows Vista and later) Displays information from the kernel pool Allocate/Free log.

The *Quantity* parameter specifies the number of traces to be displayed. By default, the entire log is displayed.

If *Address* is specified, only traces associated with the specified address within the kernel pool Allocate/Free log are displayed.

Bit 8 (0x100)

(Windows Vista and later) Displays information from the log of IoAllocateIrp, IoCompleteRequest and IoCancelIrp calls.

The *Quantity* parameter specifies the number of traces to be displayed. By default, the entire log is displayed.

If *Address* is specified, only traces associated with the specified IRP address are displayed.

Bit 9 (0x200)

(Windows Vista and later) Displays entries in the Critical Region log.

If *Address* is specified, only entries associated with the specified thread address are displayed.

Bit 10 (0x400)

(Windows Vista and later) Displays cancelled IRPs that are currently being watched by Driver Verifier.

If *Address* is specified, only the IRP with the specified address is displayed.

Bit 11 (0x800)

(Windows 8.1 and later) Display entries from the fault injection log that is created when you select the [Systematic low resource simulation](#) option.

Image

If *Flags* is used and is not equal to 4, 8, or 0x10, *Image* specifies the name of a driver. *Image* is used to filter the information displayed by *Flags* values of 0x1 and 0x2: only the specified driver is considered. This driver must be currently verified.

Quantity

(Windows XP and later) If *Flags* is exactly equal to 0x4, *Quantity* specifies the number of fault injection records to display. If *Flags* is exactly equal to 0x8, *Quantity* specifies the number of IRQL log entries to display. If *Flags* is exactly equal to 0x40, *Quantity* specifies the number of traces displayed from the log of forced pending IRPs. If *Flags* is exactly equal to 0x80, *Quantity* specifies the number of traces displayed from the kernel pool Allocate/Free log. If *Flags* is exactly equal to 0x100, *Quantity* specifies the number of traces displayed from the log of IoAllocateIrp, IoCompleteRequest and IoCancelIrp calls.

-disable

(Windows XP and later) Clears the current Driver Verifier settings on the debug target. The clearing of these settings does not persist through a reboot. If you need to disable the Driver Verifier settings to successfully boot, set a breakpoint at nt!VerifierInitSystem and use the **!Verifier -disable** command at that point.

?

(Windows XP and later) Displays some brief Help text for this extension in the Debugger Command window.

DLL

Kdexts.dll

Additional Information

For information about [Driver Verifier](#), see the Windows Driver Kit (WDK) documentation.

For more information and downloads, see the [Driver Verifier](#) on the Windows Hardware Developer Central (WHDC).

Remarks

The following example illustrates that on 64-bit versions of Windows, the IRQL transition log is not always complete. The two entries shown are consecutive entries in the log for Processor 2. The first entry shows the IRQL going from 2 to 0. The second entry shows the IRQL going from 2 to 2. Information about how the IRQL got raised from 0 to 2 is missing.

```

When using Driver Verifier to test graphics drivers, use the [!gdikdx.verifier](#) extension instead of [!verifier](#).

The values of 4, 8, and 0x20, 0x40, 0x80, and 0x100 are special values for *Flags*. If these values are used, the special arguments listed in the **Parameters** section can be used, and the display will include only the information associated with that flag value.

If any other value for *Flags* is used, even if one or more of these bits are set, only the *Flags* and *Image* arguments are permitted. In this situation, in addition to all the other information displayed, [!verifier](#) will display the Driver Verifier options that are active, along with statistics on pool allocations, IRQL raises, spin locks, and trims.

If *Flags* equals 0x20, the values specified for *CompletionTime*, *CancelTime*, and *ForceCancellation* are used by the Driver Hang Verification option of Driver Verifier. These new values take effect immediately and last until the next boot. When you reboot, they revert to their default values.

Also, if *Flags* equals 0x20 (with or without additional parameters), the Driver Hang Verification log is printed. For information on interpreting the log, see the Driver Hang Verification section of the Driver Verifier documentation in the Windows Driver Kit (WDK) documentation.

Here is an example of the [!verifier](#) extension on a Windows 7 computer.

```
2: kd> !verifier 0xf

Verify Level 9bb ... enabled options are:
```

```
Special pool
Special irql
All pool allocations checked on unload
Io subsystem checking enabled
Deadlock detection enabled
DMA checking enabled
Security checks enabled
Miscellaneous checks enabled
```

!vm

5/31/2017 • 2 min to read • [Edit Online](#)

The **!vm** extension displays summary information about virtual memory use statistics on the target system.

```
!vm [Flags]
```

Parameters

Flags

Specifies what information will be displayed in the output from this command. This can be any sum of the following bits. The default is 0, which causes the display to include system-wide virtual memory statistics as well as memory statistics for each process.

Bit 0 (0x1)

Causes the display to omit process-specific statistics.

Bit 1 (0x2)

Causes the display to include memory management thread stacks.

Bit 2 (0x4)

(Windows XP and later) Causes the display to include terminal server memory usage.

Bit 3 (0x8)

(Windows XP and later) Causes the display to include the page file write log.

Bit 4 (0x10)

(Windows XP and later) Causes the display to include working set owner thread stacks.

Bit 5 (0x20)

(Windows Vista and later) Causes the display to include kernel virtual address usage.

Environment

Modes	kernel mode only
-------	------------------

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

The **!memusage** extension command can be used to analyze physical memory usage. For more information about memory management, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Here is an example of the short output produced when *Flags* is 1:

```
kd> !vm 1

*** Virtual Memory Usage ***
Physical Memory: 16270 ( 65080 Kb)
Page File: \??\E:\pagefile.sys
  Current: 98304Kb Free Space: 61044Kb
Minimum: 98304Kb Maximum: 196608Kb
  Available Pages: 5543 ( 22172 Kb)
  ResAvail Pages: 6759 ( 27036 Kb)
  Locked IO Pages: 112 ( 448 Kb)
Free System PTEs: 45089 ( 180356 Kb)
  Free NP PTEs: 5145 ( 20580 Kb)
  Free Special NP: 336 ( 1344 Kb)
  Modified Pages: 714 ( 2856 Kb)
  NonPagedPool Usage: 877 ( 3508 Kb)
  NonPagedPool Max: 6252 ( 25008 Kb)
  PagedPool 0 Usage: 729 ( 2916 Kb)
  PagedPool 1 Usage: 432 ( 1728 Kb)
  PagedPool 2 Usage: 436 ( 1744 Kb)
  PagedPool Usage: 1597 ( 6388 Kb)
  PagedPool Maximum: 13312 ( 53248 Kb)
  Shared Commit: 1097 ( 4388 Kb)
  Special Pool: 229 ( 916 Kb)
  Shared Process: 1956 ( 7824 Kb)
  PagedPool Commit: 1597 ( 6388 Kb)
  Driver Commit: 828 ( 3312 Kb)
  Committed pages: 21949 ( 87796 Kb)
  Commit limit: 36256 ( 145024 Kb)
```

All memory use is listed in pages and in kilobytes. The most useful information in this display is the following:

PARAMETER	MEANING
physical memory	Total physical memory in the system.
available pages	Number of pages of memory available on the system, both virtual and physical.
nonpaged pool usage	The amount of pages allocated to the nonpaged pool. The nonpaged pool is memory that cannot be swapped out to the paging file, so it must always occupy physical memory. If this number is too large, this is usually an indication that there is a memory leak somewhere in the system.

[Send comments about this topic to Microsoft](#)

!vpb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!vpb** extension displays a volume parameter block (VPB).

!vpb Address

Parameters

Address

Specifies the hexadecimal address of the VPB.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about VPBs, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Here is an example. First, the device tree is displayed with the **!devnode** extension:

```
kd> !devnode 0 1
Dumping IopRootDeviceNode (= 0x80e203b8)
DevNode 0x80e203b8 for PDO 0x80e204f8
  InstancePath is "HTREE\ROOT\0"
  State = DeviceNodeStarted (0x308)
  Previous State = DeviceNodeEnumerateCompletion (0x30d)
  DevNode 0x80e56dc8 for PDO 0x80e56f18
    InstancePath is "Root\dmio\0000"
    ServiceName is "dmio"
    State = DeviceNodeStarted (0x308)
    Previous State = DeviceNodeEnumerateCompletion (0x30d)
  DevNode 0x80e56ae8 for PDO 0x80e56c38
    InstancePath is "Root\ftdisk\0000"
    ServiceName is "ftdisk"
    State = DeviceNodeStarted (0x308)
    Previous State = DeviceNodeEnumerateCompletion (0x30d)
  DevNode 0x80e152a0 for PDO 0x80e15cb8
    InstancePath is "STORAGE\Volume\1&30a96598&0&Signature5C34D70COffset7E00Length60170A00"
    ServiceName is "VolSnap"
    TargetDeviceNotify List - f 0xe1250938 b 0xe14b9198
    State = DeviceNodeStarted (0x308)
    Previous State = DeviceNodeEnumerateCompletion (0x30d)
....
```

The last device node listed is a volume. Examine its physical device object (PDO) with the **!devobj** extension:

```
kd> !devobj 80e15cb8
Device object (80e15cb8) is for:
  HarddiskVolume1 \Driver\Ftdisk DriverObject 80e4e248
  Current Irp 00000000 RefCount 14 Type 00000007 Flags 00001050
  Vpb 80e15c30 DevExt 80e15d70 DevObjExt 80e15e40 Dope 80e15bd8 DevNode 80e152a0
  ExtensionFlags (0000000000)
  AttachedDevice (Upper) 80e14c60 \Driver\VolSnap
Device queue is not busy.
```

The address of this device's VPB is included in this listing. Use this address with the **!vpb** extension:

```
kd> !vpb 80e15c30
Vpb at 0x80e15c30
Flags: 0x1 mounted
DeviceObject: 0x80de5020
RealDevice: 0x80e15cb8
RefCount: 14
Volume Label: MY-DISK-C
```

[Send comments about this topic to Microsoft](#)

!vpdd

5/26/2017 • 1 min to read • [Edit Online](#)

The **!vpdd** extension is obsolete. Use **!vtop** or **!ptov** instead.

[Send comments about this topic to Microsoft](#)

!vtop

5/31/2017 • 2 min to read • [Edit Online](#)

The **!vtop** extension converts a virtual address to the corresponding physical address, and displays other page table and page directory information.

Syntax

```
!vtop PFN VirtualAddress
!vtop 0 VirtualAddress
```

Parameters

DirBase

Specifies the directory base for the process. Each process has its own virtual address space. Use the [!process](#) extension to determine the directory base for a process.

PFN

Specifies the page frame number (PFN) of the directory base for the process.

0

Causes **!vtop** to use the current [process context](#) for address translation.

VirtualAddress

Specifies the virtual address whose page is desired.

DLL

Kdexts.dll

Additional Information

For other methods of achieving these results, see [Converting Virtual Addresses to Physical Addresses](#). Also see [!ptov](#). For information about page tables and page directories, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon.

Remarks

To use this command, first use the [!process](#) extension to determine the directory base of the process. The page frame number (PFN) of this directory base can be found by removing the three trailing hexadecimal zeros (in other words, by right-shifting the number 12 bits).

Here is an example:

```
kd> !process 0 0
**** NT ACTIVE PROCESS DUMP ****
....
PROCESS ff779190 SessionId: 0 Cid: 04fc Peb: 7ffdf000 ParentCid: 0394
DirBase: 098fd000 ObjectTable: e1646b30 TableSize: 8.
Image: MyApp.exe
```

Since the directory base is 0x098FD000, its PFN is 0x098FD.

```
kd> !vtop 98fd 12f980
Pdi 0 Pti 12f
0012f980 09de9000 pfn(09de9)
```

Notice how the trailing three zeros are optional. The **!vtop** extension displays the page directory index (PDI), the page table index (PTI), the virtual address that you had originally input, the physical address of the beginning of the physical page, and the page frame number (PFN) of the page table entry (PTE).

If you want to convert the virtual address 0x0012F980 to a physical address, you simply have to take the last three hexadecimal digits (0x980) and add them to the physical address of the beginning of the page (0x09DE9000). This gives the physical address 0x09DE9980.

If you forget to remove the three zeros, and pass the full directory base to **!vtop** instead of the PFN, the results will usually be correct. This is because when **!vtop** receives a number too large to be a PFN, it right-shifts it twelve bits and uses that number instead:

```
kd> !vtop 98fd 12f980
Pdi 0 Pti 12f
0012f980 09de9000 pfn(09de9)

kd> !vtop 98fd000 12f980
Pdi 0 Pti 12f
0012f980 09de9000 pfn(09de9)
```

However, it is better to always use the PFN, because some directory base values will not be converted in this manner.

[Send comments about this topic to Microsoft](#)

!wdmaud

5/31/2017 • 1 min to read • [Edit Online](#)

Displays a variety of WDM Audio (WDMAud) structures.

`!wdmaud Address Flags`

Parameters

Address

Specifies the address of the structure to be displayed.

Flags

Specifies the information to display. This must include exactly one of the bits 0x1, 0x2, 0x4, and 0x8. The 0x100 bit can be added to any of these.

Bit 0 (0x1)

Displays a list of all IOCTLs that have been sent to wdmaud.sys. When this is used, *Address* should specify the address of the **WdmaIoctlHistoryListHead**. If the 0x100 bit is set, the display also includes the **pContext** that each IOCTL was sent with.

Bit 1 (0x2)

Displays a list of all IRPs that WDMAud has marked as pending. When this is used, *Address* should specify the address of the **WdmaPendingIrpListHead**. If the 0x100 bit is set, the display also includes the context on which each IRP was allocated.

Bit 2 (0x4)

Displays a list of all MDLs that WDMAud has allocated. When this is used, *Address* should specify the address of the **WdmaAllocatedMdListHead**. If the 0x100 bit is set, the display also includes the context on which each MDL was allocated.

Bit 3 (0x8)

Displays a list of all active contexts attached to wdmaud.sys. When this is used, *Address* should specify the address of the **WdmaContextListHead**. If the 0x100 bit is set, the display also includes the data members of each context structure.

Bit 8 (0x100)

Causes the display to include verbose information.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable

Additional Information

For information about WDM audio architecture and audio drivers, see the Windows Driver Kit (WDK) documentation.

Remarks

The contexts attached to wdmaud.sys (**pContext**) contain most of the state data for each device. Whenever wdmaud.drv is loaded into a new process, wdmaud.sys is notified of its arrival. Whenever wdmaud.drv is unloaded, wdmaud.sys cleans up any allocations made in that context.

[Send comments about this topic to Microsoft](#)

!whattime

5/31/2017 • 1 min to read • [Edit Online](#)

The **!whattime** extension converts a tick count into a standard time value.

```
!whattime Ticks
```

Parameters

Ticks

The number of ticks.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

The output is displayed as *HH:MM:SS.mmm*. Here is an example:

```
kd> !whattime 29857ae4
696613604 Ticks in Standard Time: 15:02:16.040s
```

[Send comments about this topic to Microsoft](#)

!whatperftime

5/31/2017 • 1 min to read • [Edit Online](#)

The **!whatperftime** extension converts a high-resolution performance counter value into a standard time value.

```
!whatperftime Count
```

Parameters

Count

The performance counter clock value.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

You can use **!whatperftime** to convert values retrieved by calling **QueryPerformanceCounter**. Performance counter time values are also found in software traces.

The output is displayed as *HH:MM:SS.mmm*. Here is an example:

```
kd> !whatperftime 304589
3163529 Performance Counter in Standard Time: .004.313s
```

[Send comments about this topic to Microsoft](#)

!whea

5/31/2017 • 2 min to read • [Edit Online](#)

The **!whea** extension displays top-level Windows Hardware Error Architecture (WHEA) information.

```
!whea
```

DLL

Windows 2000	Unavailable
Windows XP	Unavailable
Windows Server 2003	Unavailable
Windows Vista and later	Kdexts.dll

This extension can be used only in Windows Vista and later versions of Windows.

Additional Information

The **!errrec** and **!errpkt** extensions can be used to display additional WHEA information. For general information about WHEA, see [Windows Hardware Error Architecture \(WHEA\)](#) in the Windows Driver Kit (WDK) documentation.

Remarks

The following example shows the (truncated) output of the **!whea** extension:

```
3: kd> !whea

[Send comments about this topic to Microsoft](#)

!wsle

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wsle** extension displays all working set list entries (WSLEs).

Syntax

```
!wsle [Flags [Address]]
```

Parameters

Flags

Specifies the information to include in the display. This can be any combination of the following bits. The default is zero. If this is used, only basic information about the working set is displayed.

Bit 0 (0x1)

Causes the display to include information about each WSLE's address, age, lock status, and reference count. If a WSLE has an invalid page table entry (PTE) or page directory entry (PDE) associated with it, this is also displayed.

Bit 1 (0x2)

Causes the display to include the total number of valid WSLEs, the index of the last WSLE, and the index of the first free WSLE.

Bit 2 (0x4)

Causes the display to include the total number of free WSLEs, as well as the index of each free WSLE. If bit 1 is also set, then a check is done to make sure that the number of free WSLEs plus the number of valid WSLEs is actually equal to the total number of WSLEs.

Address

Specifies the address of the working set list. If this is omitted, the default working set list is used. Specifying zero for *Address* is the same as omitting it.

DLL

Kdexts.dll

Additional Information

For information about working sets, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

This extension can take a significant amount of time to execute.

Here is an example from an x86 target computer running Windows Server 2003:

```
kd> !wsle 3

Working Set @ c0503000
FirstFree:      a7  FirstDynamic:        4
LastEntry      23d  NextSlot:        4  LastInitialized:    259
NonDirect      65  HashTable:        0  HashTableSize:      0
```

```
Reading the WSLE data...
```

Virtual Address	Age	Locked	ReferenceCount
c0300203	0	1	1
c0301203	0	1	1
c0502203	0	1	1
c0503203	0	1	1
c01ff201	0	0	1
77f74d19	3	0	1
7ffdfa01	2	0	1
c0001201	0	0	1

```
.....
```

```
Reading the WSLE data...
```

```
Valid WSLE entries = 0xa7
found end @ wsle index 0x259
```

```
.....
```

[Send comments about this topic to Microsoft](#)

!zombies

5/31/2017 • 1 min to read • [Edit Online](#)

The **!zombies** extension displays all dead ("zombie") processes or threads.

```
!zombies [Flags [RestartAddress]]
```

Parameters

Flags

Specifies what will be displayed. Possible values include:

1

Displays all zombie processes. (This is the default.)

2

Displays all zombie threads.

RestartAddress

Specifies the hexadecimal address at which to begin the search. This is useful if the previous search was terminated prematurely. The default is zero.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable

Additional Information

To see a list of all processes and threads, use the [!process](#) extension.

For general information about processes and threads in kernel mode, see [Changing Contexts](#). For more information about analyzing processes and threads, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

Zombie processes are dead processes that have not yet been removed from the process list. Zombie threads are analogous.

This extension is available only for Windows 2000.

[Send comments about this topic to Microsoft](#)

User-Mode Extensions

5/26/2017 • 1 min to read • [Edit Online](#)

This section of the reference describes extension commands that are primarily used during user-mode debugging.

The debugger will automatically load the proper version of these extension commands. Unless you have manually loaded a different version, you do not have to keep track of the DLL versions being used. See [Using Debugger Extension Commands](#) for a description of the default module search order. See [Loading Debugger Extension DLLs](#) for an explanation of how to load extension modules.

Each extension command reference page lists the DLLs that expose that command. Use the following rules to determine the proper directory from which to load this extension DLL:

- If your target application is running on Windows XP or a later version of Windows, use `winxp\Ntsdexts.dll`.

In addition, user-mode extensions that are not specific to any single operating system can be found in `winext\Uext.dll`.

[Send comments about this topic to Microsoft](#)

!avrfl

5/31/2017 • 5 min to read • [Edit Online](#)

The **!avrfl** extension controls the settings of [Application Verifier](#) and displays a variety of output produced by Application Verifier.

```
!avrfl
!avrfl -vs { Length | -a Address }
!avrfl -hp { Length | -a Address }
!avrfl -cs { Length | -a Address }
!avrfl -dlls [ Length ]
!avrfl -trm
!avrfl -ex [ Length ]
!avrfl -threads [ ThreadID ]
!avrfl -tp [ ThreadID ]
!avrfl -srw [ Address | Address Length ] [ -stats ]
!avrfl -leak [ -m ModuleName ] [ -r ResourceType ] [ -a Address ] [ -t ]
!avrfl -trace TraceIndex
!avrfl -cnt
!avrfl -brk [BreakEventType]
!avrfl -flt [EventType Probability]
!avrfl -flt break EventType
!avrfl -flt stacks Length
!avrfl -trg [ Start End | dll Module | all ]
!avrfl -settings
!avrfl -skp [ Start End | dll Module | all | Time ]
```

Parameters

-vs { Length | -a Address }

Displays the virtual space operation log. *Length* specifies the number of records to display, starting with the most recent. *Address* specifies the virtual address. Records of the virtual operations that contain this virtual address are displayed.

-hp { Length | -a Address }

Displays the heap operation log. *Address* specifies the heap address. Records of the heap operations that contain this heap address are displayed.

-cs { Length | -a Address }

Displays the critical section delete log. *Length* specifies the number of records to display, starting with the most recent. *Address* specifies the critical section address. Records for the particular critical section are displayed when *Address* is specified.

-dlls [Length]

Displays the DLL load/unload log. *Length* specifies the number of records to display, starting with the most recent.

-trm

Displays a log of all terminated and suspended threads.

-ex [Length]

Displays the exception log. Application Verifier tracks all the exceptions in the application.

-threads [ThreadID]

Displays information about threads in the target process. For child threads, the stack size and the **CreateThread** flags specified by the parent are also displayed. If you provide a thread ID, information for only that thread is

displayed.

-tp [ThreadID]

Displays the threadpool log. This log contains stack traces for various operations such as changing the thread affinity mask, changing thread priority, posting thread messages, and initializing or uninitialized COM from within the threadpool callback. If you provide a thread ID, information for that thread only is displayed.

-srw [Address | Address Length] [-stats]

Displays the Slim Reader/Writer (SRW) log. If you specify *Address*, records for the SRW lock at that address are displayed. If you specify *Address* and *Length*, records for SRW locks in that address range are displayed. If you include the **-stats** option, the SRW lock statistics are displayed.

-leak [-m ModuleName] [-r ResourceType] [-a Address] [-t]

Displays the outstanding resources log. These resources may or may not be leaks at any given point. If you specify *Modulename* (including the extension), all outstanding resources in the specified module are displayed. If you specify *ResourceType*, all outstanding resources of that resource type are displayed. If you specify *Address*, records of outstanding resources with that address are displayed. *ResourceType* can be one of the following:

Heap: Displays heap allocations using Win32 Heap APIs

Local: Displays Local/Global allocations

CRT: Displays allocations using CRT APIs

Virtual: Displays Virtual reservations

BSTR: Displays BSTR allocations

Registry: Displays Registry key opens

Power: Displays power notification objects

Handle: Displays thread, file, and event handle allocations

-trace TraceIndex Displays a stack trace for the specified trace index. Some structures use this 16-bit index number to identify a stack trace. This index points to a location within the stack trace database.

-cnt Displays a list of global counters.

-brk [BreakEventType] Specifies a break event. *BreakEventType* is the type number of the break event. For a list of possible types, and a list of the current break event settings, enter **!avrf -brk**.

-flt [EventType Probability] Specifies a fault injection. *EventType* is the type number of the event. *Probability* is the frequency with which the event will fail. This can be any integer between 0 and 1,000,000 (0xF4240). If you enter **!avrf -flt** with no additional parameters, the current fault injection settings are displayed.

-flt break EventType Causes Application Verifier to break into the debugger each time this fault, specified by *EventType*, is injected.

-flt stacks Length Displays *Length* number of stack traces for the most recent fault-injected operations.

-trg [Start End | dll Module | all] Specifies a target range. *Start* is the beginning address of the target range. *End* is the ending address of the target range. *Module* specifies the name (including the .exe or .dll extension, but not including the path) of a module to be targeted. If you enter **-trg all**, all target ranges are reset. If you enter **-trg** with no additional parameters, the current target ranges are displayed.

-skp [Start End | dll Module | all | Time] Specifies an exclusion range. *Start* is the beginning address of the exclusion range. *End* is the ending address of the exclusion range. *Module* specifies the name of a module to be targeted or excluded. *Module* specifies the name (including the .exe or .dll extension, but not including the path) of a module to be excluded. If you enter **-skp all**, all target ranges or exclusion ranges are reset. If you enter a *Time*

value, all faults are suppressed for *Time* milliseconds after execution resumes.

DLL

exts.dll

Additional Information

For information about how to download and install Application Verifier and its documentation, see [Application Verifier](#).

Remarks

When the **!avr** extension is used with no parameters, it displays the current Application Verifier options. If the **Full page heap** or **Fast fill heap** option has been enabled, information about active page heaps is displayed as well.

For some examples, see "Heap Operation Logs" in the Application Verifier documentation.

If an Application Verifier Stop has occurred, the **!avr** extension with no parameters will reveal the nature of the stop and its cause. For some examples, see "Debugging Application Verifier Stops" in the Application Verifier documentation.

If symbols for ntdll.dll and verifier.dll are missing, the **!avr** extension generates an error message. For information about how to address this problem, see "Setting Up a Debugger for Application Verifier" in the Application Verifier documentation.

[Send comments about this topic to Microsoft](#)

!critsec

5/31/2017 • 1 min to read • [Edit Online](#)

The **!critsec** extension displays a critical section.

```
!critsec Address
```

Parameters

Address

Specifies the hexadecimal address of the critical section.

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Ntsdexts.dll

Additional Information

For other commands and extensions that can display critical section information, see [Displaying a Critical Section](#).

For information about critical sections, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

If you do not know the address of the critical section, you should use the [!ntsdexts.locks](#) extension. This displays all critical sections that have been initialized by calling [RtlInitializeCriticalSection](#).

Here is an example:

```
0:000> !critsec 3a8c0e9c

CritSec +3a8c0e9c at 3A8C0E9C
LockCount      1
RecursionCount 1
OwningThread   99
EntryCount     472
ContentionCount 1
*** Locked
```

[Send comments about this topic to Microsoft](#)

!dp (!ntsdexts.dp)

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dp** extension in Ntsdexts.dll displays a CSR process.

This extension command should not be confused with the **dp (Display Memory)** command, or with the **!kdext*.dp** extension command.

```
!dp [v] [ PID | CSR-Process ]
```

Parameters

v

Verbose mode. Causes the display to include structure and thread list.

PID

Specifies the process ID of the CSR process.

CSR-Process

Specifies the hexadecimal address of the CSR process.

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Ntsdexts.dll

Remarks

This extension displays the process address, process ID, sequence number, flags, and reference count. If verbose mode is selected, additional details are displayed, and thread information is shown for each process.

If no process is specified, all processes are displayed.

See also

!dt

[Send comments about this topic to Microsoft](#)

!dreg

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dreg** extension displays registry information.

```
!dreg [-d|-w] KeyPath[!Value]  
!dreg
```

Parameters

-d

Causes binary values to be displayed as DWORDs.

-w

Causes binary values to be displayed as WORDs.

KeyPath

Specifies the registry key path. It can begin with any of the following abbreviations:

hklm

HKEY_LOCAL_MACHINE

hkcu

HKEY_CURRENT_USER

hkcr

HKEY_CLASSES_ROOT

hku

HKEY_USERS

If no abbreviation is used, HKEY_LOCAL_MACHINE is assumed.

Value

Specifies the name of the registry value to be displayed. If an asterisk (*) is used, all values are displayed. If *Value* is omitted, all subkeys are displayed.

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Ntsdexts.dll

Additional Information

For information about the registry, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The **!dreg** extension can be used to display the registry during user-mode debugging.

It is most useful during remote debugging, as it allows you to browse the registry of the remote machine. It is also useful when controlling the user-mode debugger from the kernel debugger, because you cannot run a standard registry editor on the target machine when it is frozen. (You can use the **.sleep** command for this purpose as well. See [Controlling the User-Mode Debugger from the Kernel Debugger](#) for details.)

It is also useful when debugging locally, as the information is presented in an easily readable format.

If **!dreg** is used during kernel-mode debugging, the results shown will be for the host computer, and not the target computer. To display raw registry information for the target computer, use the **!reg** extension instead.

Here are some examples. The following will display all subkeys of the specified registry key:

```
!dreg hkcu\Software\Microsoft
```

The following will display all values in the specified registry key:

```
!dreg System\CurrentControlSet\Services\Tcpip!*
```

The following will display the value Start in the specified registry key:

```
!dreg System\CurrentControlSet\Services\Tcpip!Start
```

Typing **!dreg** without any arguments will display some brief Help text for this extension in the Debugger Command window.

[Send comments about this topic to Microsoft](#)

!dt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dt** extension displays information about a CSR thread.

This extension command should not be confused with the **dt (Display Type)** command.

```
!dt [v] CSR-Thread
```

Parameters

v

Verbose mode.

CSR-Thread

Specifies the hexadecimal address of the CSR thread.

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Ntsdexts.dll

Remarks

This extension displays the thread, process, client ID, flags, and reference count associated with the CSR thread. If verbose mode is selected, the display will also include list pointers, thread handle, and the wait block.

See also

[!dp \(!ntsdexts.dp\)](#)

[Send comments about this topic to Microsoft](#)

!evlog

5/31/2017 • 5 min to read • [Edit Online](#)

The **!evlog** extension displays, changes, or backs up the event log.

```
!evlog addsource [-d] [-s Source] [-t Type] [-f MsgFile]
!evlog backup [-d] [-l EventLog] [-f BackupFile]
!evlog clear [-!] [-d] [-l EventLog] [-f BackupFile]
!evlog info
!evlog option [-d] [-!] [-n Count] [-l EventLog] [-+ | -r RecordBound]] [-o Order] [-w Width]
!evlog read [-d] [-l EventLog] [-s Source] [-e ID] [-c Category] [-t Type] [-n Count] [-r Record]
!evlog report [-s Source] [-e ID] [-c Category] [-t Type] Message
!evlog [Option] -?
```

Parameters

addsource

Adds an event source to the registry. By default, this only adds events from the **DebuggerExtensions** source (to support **!evlog report**).

backup

Makes a backup of the specified event log and writes it to a file.

clear

Erases the specified event log, and optionally creates a file recording its old contents.

info

Displays summary information about the event log.

option

Sets the default search options. These options will be used in future **!evlog read** commands.

read

Displays a list of events logged to the specified event log. Details of this display -- such as the number of records displayed and the chronological order of the display -- can be controlled by the **!evlog read** parameters or by a previous use of **!evlog option**.

report

Writes an event record to the application event log.

-d

Specifies that all default values should be used. The **-d** option is only required if you are omitting all other parameters. However, with the **!evlog option** command this option displays the existing default settings.

-!

With **!evlog option**, this resets all defaults. With **!evlog clear**, this prevents a backup file from being written.

Source

Specifies the event source. The default value is **DebuggerExtensions**.

Type

Specifies the success type. Possible *Type* values are 1 (Error), 2 (Warning), 4 (Information), 8 (Audit_Success), or 16 (Audit_Failure). A value of 0 represents Success. For **!evlog read** and **!evlog report**, the default is Success (0). For **!evlog addsource**, these bits can be combined, and the default is all bits (31).

MsgFile

Specifies the path and file name of the message file. If the path is omitted, the directory of the current Uext.dll is used.

EventLog

For **!evlog read**, **!evlog backup**, and **!evlog clear**, *EventLog* specifies the event log from which to read. The possible values are **Application**, **System**, and **Security**. The default is **Application**.

For **!evlog option**, *EventLog* specifies the event log whose maximum count is to be set. The possible values are **All**, **Application**, **System**, and **Security**. The default is **All**.

BackupFile

Specifies the path and file name of the backup file. The default location is the current directory. The default file name is *EventLog*_backup.evt, where *EventLog* is the event log used in this command. If this file already exists, the command will be terminated.

Count

Specifies the maximum number of records to retrieve. The default is 20.

-+

Specifies that the current maximum record number should be the highest record number retrieved in future **!evlog read** commands. (In other words, no records will be shown as long as the search is performed forward.)

RecordBound

Specifies the highest record number to retrieve in future **!evlog read** commands. If zero is specified, no bound is set -- this is the default.

Record

If **-n **** Count** is not included, **-r **** Record** specifies the record number to retrieve. If **-n **** Count** is included, *Record* specifies the record number at which the display should begin.

Order

Specifies the search order, either **Forwards** or **Backwards**. The default is **Forwards**. A backward search order causes searches to start from the most recent record logged to the event log, and continue in reverse-chronological order as matching records are found.

Width

Specifies the data display width, in characters. This is the width displayed in the Data section. The default is 8 characters.

ID

Specifies the prefix to display before the event. Possible values are 0 (no prefix), 1000 (Information), 2000 (Success), 3000 (Warning), and 4000 (Error).

The default is 0.

Category

Specifies the event category.

Possible values are 0 (no category), 1 (Devices), 2 (Disk), 3 (Printers), 4 (Services), 5 (Shell), 6 (System_Event), and 7 (Network). The default is 0.

Message

Specifies a text message to add to the event description.

Option

Specifies the **!evlog** option whose help text is to be displayed.

-?

Displays some brief Help text for this extension or one of its options in the Debugger Command window.

DLL

Windows 2000	Uext.dll
Windows XP and later	Uext.dll

The **!evlog** extension can only be used during live debugging.

Remarks

After you have added an event source to the registry with **!evlog addsource**, you can view the values with **!dreg**. For example:

```
0:000> !dreg hklm\system\currentcontrolset\services\eventlog\Application\<source>!*
```

The **!evlog option** command is used to set new defaults for the **!evlog read** command. This lets you avoid retyping all the parameters every time you use **!evlog read**. Setting a maximum record bound with the **-n** parameter or the **-r **** Records** parameter allows you to terminate all searches after a known record number is encountered. This can be useful if you are only interested in all records logged after a certain event.

Before using **!evlog report**, you should use **!evlog addsource** to configure an event source in the registry. After this has been configured, the event viewer will recognize the various event IDs.

Here is an example of the **!evlog info** extension:

```
## 0:000> !evlog info -?

Application Event Log:
# Records      : 4362
  Oldest Record # : 1
  Newest Record # : 4362
##  Event Log Full : false

System Event Log:
# Records      : 2296
  Oldest Record # : 1
  Newest Record # : 2296
##  Event Log Full : false

Security Event Log:
# Records      : 54544
  Oldest Record # : 1
  Newest Record # : 54544
##  Event Log Full : false

0:000> !evlog option -n 4
## Default EvLog Option Settings:

Max Records Returned: 4
Search Order:          Backwards
## Data Display Width: 8

Bounding Record Numbers:
  Application Event Log: 0
  System Event Log:      0
##  Security Event Log:  0
```

```
0:000> !evlog read -l application
----- 01 -----
Record #: 4364

[Send comments about this topic to Microsoft](#)

!findstack

5/31/2017 • 1 min to read • [Edit Online](#)

The **!findstack** extension locates all of the stacks that contain a specified symbol or module.

```
!findstack Symbol [DisplayLevel]
!findstack -?
```

Parameters

Symbol

Specifies a symbol or module.

DisplayLevel

Specifies what the display should contain. This can be any one of the following values. The default value is 1.

0

Displays only the thread ID for each thread that contains *Symbol*.

1

Displays both the thread ID and the frame for each thread that contains *Symbol*.

2

Displays the entire thread stack for each thread that contains *Symbol*.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Uext.dll
Windows XP and later	Uext.dll

Additional Information

For more information about stack traces, see the [k, kb, kc, kd, kp, kP, kv \(Display Stack Backtrace\)](#) commands.

Remarks

The [!stacks](#) kernel-mode extension also display information about stacks, including a brief summary of the state of every thread.

The following are some examples of the output from this extension:

```
0:023> !uext.findstack wininet
Thread 009, 2 frame(s) match
* 06 03eaffac 771d9263 wininet!ICAsyncThread::SelectThread+0x22a
* 07 03eaffb4 7c80b50b wininet!ICAsyncThread::SelectThreadWrapper+0xd

Thread 011, 2 frame(s) match
* 04 03f6ffb0 771cda1d wininet!AUTO_PROXY_DLLS::DoThreadProcessing+0xa1
* 05 03f6ffb4 7c80b50b wininet!AutoProxyThreadFunc+0xb

Thread 020, 6 frame(s) match
* 18 090dfde8 771db73a wininet!CheckForNoNetOverride+0x9c
* 19 090dfe18 771c5e4d wininet!InternetAutodialIfNotLocalHost+0x220
* 20 090dfe8c 771c5d6a wininet!ParseUrlForHttp_Fsm+0x135

!gatom

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gatom** extension displays the global atom table.

```
!gatom
```

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Ntsdexts.dll

Additional Information

For information about the global atom table, see the Microsoft Windows SDK documentation.

[Send comments about this topic to Microsoft](#)

!igrep

5/31/2017 • 1 min to read • [Edit Online](#)

The **!igrep** extension searches for a pattern in disassembly.

```
!igrep [Pattern [StartAddress]]
```

Parameters

Pattern

Specifies the pattern to search for. If omitted, the last *Pattern* is used.

StartAddress

Specifies the hexadecimal address at which to begin searching. If omitted, the current program counter is used.

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Unavailable

[Send comments about this topic to Microsoft](#)

!locks (!ntsdexts.locks)

5/31/2017 • 1 min to read • [Edit Online](#)

The **!locks** extension in Ntsdexts.dll displays a list of critical sections associated with the current process.

This extension command should not be confused with the **!kdext*.locks** extension command.

```
!locks [Options]
```

Parameters

Options

Specifies the amount of information to be displayed. Any combination of the following options can be used:

-v

Causes the display to include all critical sections, even those that are not currently owned.

-o

(Windows XP and later) Causes the display to only include orphaned information (pointers that do not actually point to valid critical sections).

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Ntsdexts.dll

Additional Information

For other commands and extensions that can display critical section information, see [Displaying a Critical Section](#).

For information about critical sections, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

This extension command shows all critical sections that have been initialized by calling **RtlInitializeCriticalSection**. If there are no critical sections, then no output will result.

Here is an example:

```
0:000> !locks

CritSec w3svc!g_pWamDictator+a0 at 68C2C298
LockCount          0
RecursionCount    1
OwningThread      d1
EntryCount         1
ContentionCount   0
*** Locked

CritSec SMTPSVC+66a30 at 67906A30
LockCount          0
RecursionCount    1
OwningThread      d0
EntryCount         1
ContentionCount   0
*** Locked
```

[Send comments about this topic to Microsoft](#)

!mapped_file

5/31/2017 • 1 min to read • [Edit Online](#)

The **!mapped_file** extension displays the name of the file that backs the file mapping that contains a specified address.

```
!mapped_file Address
```

Parameters

Address

Specifies the address of the file mapping. If *Address* is not in a mapping, the command fails.

DLL

Windows 2000	Uext.dll
Windows XP and later	Uext.dll

The **!mapped_file** extension can only be used during live, nonremote debugging.

Additional Information

For more information about file mapping, see [MapViewOfFile](#) in the Windows SDK.

Remarks

Here are three examples. The first two addresses used are mapped from a file, and the third is not.

```
0:000> !mapped_file 4121ec
Mapped file name for 004121ec: '\Device\HarddiskVolume2\CODE\TimeTest\Debug\TimeTest.exe'

0:000> !mapped_file 77150000
Mapped file name for 77150000: '\Device\HarddiskVolume2\Windows\System32\kernel32.dll'

0:000> !mapped_file 80310000
No information found for 80310000: error 87
```

[Send comments about this topic to Microsoft](#)

!runaway

5/31/2017 • 1 min to read • [Edit Online](#)

The **!runaway** extension displays information about the time consumed by each thread.

```
!runaway [Flags]
```

Parameters

Flags

Specifies the kind of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x1.

Bit 0 (0x1)

Causes the debugger to show the amount of user time consumed by each thread.

Bit 1 (0x2)

Causes the debugger to show the amount of kernel time consumed by each thread.

Bit 2 (0x4)

Causes the debugger to show the amount of time that has elapsed since each thread was created.

DLL

Windows 2000	Uext.dll Ntsdexts.dll
Windows XP and later	Uext.dll Ntsdexts.dll

The **!runaway** extension can only be used during live debugging or when debugging crash dump files created by **.dump /mt** or **.dump /ma**.

Additional Information

For information about threads in user mode, see [Controlling Processes and Threads](#). For more information about analyzing processes and threads, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

This extension is a quick way to find out which threads are spinning out of control or consuming too much CPU time.

The display identifies each thread by the debugger's internal thread numbering and by the thread ID in hexadecimal. The debugger IDs are also shown.

Here is an example:

```
0:001> !runaway 7
```

User Mode Time

Thread	Time
0:55c	0:00:00.0093
1:1a4	0:00:00.0000

Kernel Mode Time

Thread	Time
0:55c	0:00:00.0140
1:1a4	0:00:00.0000

Elapsed Time

Thread	Time
0:55c	0:00:43.0533
1:1a4	0:00:25.0876

[Send comments about this topic to Microsoft](#)

!threadtoken

5/31/2017 • 1 min to read • [Edit Online](#)

The **!threadtoken** extension displays the impersonation state of the current thread.

```
!threadtoken
```

DLL

Windows 2000	Ntsdexts.dll
Windows XP and later	Unavailable

Additional Information

For information about threads and impersonation, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The **!threadtoken** extension is obsolete in Windows XP and later versions of Windows. Use **!token** instead.

If the current thread is impersonating, the token that this thread is using will be displayed.

Otherwise, a message reading "Thread is not impersonating" will appear. The process token will then be displayed.

Tokens will be displayed in the same format that **!handle** uses when displaying token handles.

Here is an example:

```
0:000> ~
. 0  id: 1d0.55c  Suspend: 1 Teb 7ffde000 Unfrozen
# 1  id: 1d0.1a4  Suspend: 1 Teb 7ffdd000 Unfrozen

0:000> !threadtoken

***Thread is not impersonating, using process token***

!uniqstack

5/31/2017 • 1 min to read • [Edit Online](#)

The **!uniqstack** extension displays all of the stacks for all of the threads in the current process, excluding stacks that appear to have duplicates.

```
!uniqstack [ -b | -v | -p ] [ -n ]
```

Parameters

-b

Causes the display to include the first three parameters passed to each function.

-v

Causes the display to include frame pointer omission (FPO) information. On x86-based processors, the calling convention information is also displayed.

-p

Causes the display to include the full parameters for each function that is called in the stack trace. This listing will include each parameter's data type, name, and value. *This requires full symbol information.*

-n

Causes frame numbers to be displayed.

DLL

Windows 2000	Uext.dll
Windows XP and later	Uext.dll

Remarks

This extension is similar to the [k, kb, kc, kd, kp, kP, kv \(Display Stack Backtrace\)](#) command, except that it does not display duplicate stacks.

For example:

```
0:000> !uniqstack
```

```
Processing 14 threads, please wait
```

```
. 0 Id: f0f0f0f0.15c Suspend: 1 Teb: 00000000`7fff8000 Unfrozen
```

```
Priority: 0
```

!vadump

5/31/2017 • 1 min to read • [Edit Online](#)

The **!vadump** extension displays all virtual memory ranges and their corresponding protection information.

```
!vadump [-v]
```

Parameters

-v

Causes the display to include information about each original allocation region as well. Because individual addresses within a region can have their protection altered after memory is allocated (by **VirtualProtect**, for example), the original protection status for this larger region may not be the same as that of each range within the region.

DLL

Windows 2000	Uext.dll
Windows XP and later	Uext.dll

Additional Information

To view memory protection information for a single virtual address, use **!vprot**. For information about memory protection, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

Here is an example:

```
0:000> !vadump
BaseAddress: 00000000
RegionSize: 00010000
State: 00010000 MEM_FREE
Protect: 00000001 PAGE_NOACCESS

BaseAddress: 00010000
RegionSize: 00001000
State: 00001000 MEM_COMMIT
Protect: 00000004 PAGE_READWRITE
Type: 00020000 MEM_PRIVATE
.....
```

In this display, the State line shows the state of the memory range beginning at the specified BaseAddress. The possible state values are MEM_COMMIT, MEM_FREE, and MEM_RESERVE.

The Protect line shows the protection status of this memory range. The possible protection values are PAGE_NOACCESS, PAGE_READONLY, PAGE_READWRITE, PAGE_EXECUTE, PAGE_EXECUTE_READ, PAGE_EXECUTE_READWRITE, PAGE_WRITECOPY, PAGE_EXECUTE_WRITECOPY, and PAGE_GUARD.

The Type line shows the memory type. The possible values are MEM_IMAGE, MEM_MAPPED, and MEM_PRIVATE.

Here is an example using the **-v** parameter:

```
0:000> !vadump -v
BaseAddress: 00000000
AllocationBase: 00000000
RegionSize: 00010000
State: 00010000 MEM_FREE
Protect: 00000001 PAGE_NOACCESS

BaseAddress: 00010000
AllocationBase: 00010000
AllocationProtect: 00000004 PAGE_READWRITE
RegionSize: 00001000
State: 00001000 MEM_COMMIT
Protect: 00000004 PAGE_READWRITE
Type: 00020000 MEM_PRIVATE
.....
```

When **-v** is used, the AllocationProtect line shows the default protection that the entire region was created with. The Protect line shows the actual protection for this specific address.

[Send comments about this topic to Microsoft](#)

!vprot

5/31/2017 • 1 min to read • [Edit Online](#)

The **!vprot** extension displays virtual memory protection information.

```
!vprot [Address]
```

Parameters

Address

Specifies the hexadecimal address whose memory protection status is to be displayed.

DLL

Windows 2000	Uext.dll Ntsdexts.dll
Windows XP and later	Uext.dll

Additional Information

To view memory protection information for all memory ranges owned by the target process, use **!vadump**. For information about memory protection, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

The **!vprot** extension command can be used for both live debugging and dump file debugging.

Here is an example:

```
0:000> !vprot 30c191c
BaseAddress: 030c1000
AllocationBase: 030c0000
AllocationProtect: 00000080 PAGE_EXECUTE_WRITECOPY
RegionSize: 00011000
State: 00001000 MEM_COMMIT
Protect: 00000010 PAGE_EXECUTE
Type: 01000000 MEM_IMAGE
```

In this display, the AllocationProtect line shows the default protection that the entire region was created with. Note that individual addresses within this region can have their protection altered after memory is allocated (for example, if **VirtualProtect** is called). The Protect line shows the actual protection for this specific address. The possible protection values are PAGE_NOACCESS, PAGE_READONLY, PAGE_READWRITE, PAGE_EXECUTE, PAGE_EXECUTE_READ, PAGE_EXECUTE_READWRITE, PAGE_WRITECOPY, PAGE_EXECUTE_WRITECOPY, and PAGE_GUARD.

The State line also applies to the specific virtual address passed to **!vprot**. The possible state values are MEM_COMMIT, MEM_FREE, and MEM_RESERVE.

The Type line shows the memory type. The possible values are MEM_IMAGE, MEM_MAPPED, and MEM_PRIVATE.

Storage Kernel Debugger Extensions

5/26/2017 • 1 min to read • [Edit Online](#)

The storage kernel debugger extensions (storagekd) are used for debugging the storage drivers on Windows 8 and above operating system (OS) targets.

Extension commands that are useful for debugging storage drivers, via classppn managed storage class drivers and Storport managed storage miniport drivers, can be found in **Storagekd.dll**.

Please refer to [SCSI Miniport Extensions \(Scsikd.dll and Minipkd.dll\)](#) for debugging needs for Windows 7 and below version of OS targets.

Important You need special symbols to use this extension. For more information, see [Debugging Tools for Windows](#).

Storage kernel debugger extension commands

COMMAND	DESCRIPTION
!storagekd.storhelp	Displays help text for Storagekd.dll extension commands.
!storagekd.storclass	Displays information about the specified <i>classppn</i> device.
!storagekd.storadapter	Displays information about the specified <i>Storport</i> adapter.
!storagekd.storunit	Displays information about the specified <i>Storport</i> logical unit.
!storagekd.storloglist	Displays the <i>Storport</i> adapter's internal log entries.
!storagekd.storlogirp	Displays the <i>Storport</i> 's internal log entries for the adapter filtered for the IRP provided.
!storagekd.storlogsrb	Displays the <i>Storport</i> 's internal log entries for the adapter filtered for the Storage (or SCSI) Request Block (SRB) provided.
!storagekd.storsrb	Displays information about the specified Storage (or SCSI) Request Block (SRB).

[Send comments about this topic to Microsoft](#)

!storagekd.storadapter

5/31/2017 • 1 min to read • [Edit Online](#)

The **!storagekd.storadapter** extension displays information about the specified Storport adapter.

```
!storagekd.storadapter [Address]
```

Parameters

Address

Specifies the address of a Storport adapter device object. If *Address* is omitted, a list of all Storport adapters is displayed.

DLL

Windows 8 and later	Storagekd.dll
----------------------------	---------------

Remarks

Here is an example of the **!storagekd.storadapter** display:

1: kd> !storagekd.storadapter

```

!storagekd.storclass

5/31/2017 • 1 min to read • [Edit Online](#)

The **!storagekd.storclass** extension displays information about the specified *classpnp* device.

```
!storagekd.storclass [Address [Level]]
```

Parameters

Address

Specifies the address to the device object or device extension of a classpnp device. If *Address* is omitted, a list of all classpnp extensions is displayed.

Level

Specifies the amount of detail to display. This parameter can be set to 0, 1, or 2, with 2 giving the most detail and 0 the least. The default is 0.

!storagekd.storhelp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!storagekd.storhelp** extension displays help text for Storagekd.dll extension commands.

```
!storagekd.storhelp
```

DLL

Windows 8 and later	Storagekd.dll
----------------------------	---------------

Remarks

Here is an example of the **!storagekd.storhelp** display:

0: kd> !storagekd.storhelp

```
# Storage Debugger Extension
=====
## General Commands
-----
!storhelp      - Displays complete help of the commands provided in this KD extension
!storclass     - Dumps all class devices managed by classpnp
!storadapter   - Dumps all adapters managed by Storport
!storunit      - Dumps all disks managed by Storport

## STORPORT specific commands
-----
!storlogirp <args>      - displays internal log entries that reference the specified IRP.
                           See '!storhelp storlogirp' for details.
!storloglist <args>      - displays internal log entries. See '!storhelp storloglist' for details.
!storlogsrp <args>      - displays internal log entries that reference the specified SRB.
                           See '!storhelp storlogsrp' for details.
!storsrp <address>      - display details for the specified SCSI or STORAGE request block
```

[Send comments about this topic to Microsoft](#)

!storagekd.storlogirp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!storagekd.storlogirp** extension displays the Storport's internal log entries for the adapter filtered for the IRP provided.

```
!storagekd.storlogirp <Address> <irp> [<starting_entry> [<ending_entry>]] [L <count>]
```

Parameters

Address

Specifies the address of a Storport adapter device extension or device object.

irp

The IRP to locate.

starting_entry

The beginning entry in the range to display. If not specified, the last *count* entries will be displayed.

ending_entry

The ending entry in the range to display. If not specified, *count* entries will be displayed, beginning with the item specified by *starting_entry*.

count

Count of entries to be displayed. If not specified, a value of 50 is used.

DLL

Windows 8 and later	Storagekd.dll
----------------------------	---------------

[Send comments about this topic to Microsoft](#)

!storagekd.storloglist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!storagekd.storloglist** extension displays the Storport adapter's internal log entries.

```
!storagekd.storloglist <Address> [<starting_entry> [<ending_entry>]] [L <count>]
```

Parameters

Address

Specifies the address of a Storport adapter device extension or device object.

starting_entry

The beginning entry in the range to display. If not specified, the last *count* entries will be displayed.

ending_entry

The ending entry in the range to display. If not specified, *count* entries will be displayed, beginning with the item specified by *starting_entry*.

count

Count of entries to be displayed. If not specified, a value of 50 is used.

DLL

Windows 8 and later	Storagekd.dll

!storagekd.storlogsrb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!storagekd.storlogsrb** extension displays the Storport's internal log entries for the adapter filtered for the Storage (or SCSI) Request Block (SRB) provided.

```
!storagekd.storlogsrb <Address> <srb> [<starting_entry> [<ending_entry>]] [L <count>]
```

Parameters

Address

Specifies the address of a Storport adapter device extension or device object.

SRB

The SRB to locate.

starting_entry

The beginning entry in the range to display. If not specified, the last *count* entries will be displayed.

ending_entry

The ending entry in the range to display. If not specified, *count* entries will be displayed, beginning with the item specified by *starting_entry*.

count

Count of entries to be displayed. If not specified, a value of 50 is used.

DLL

Windows 8 and later	Storagekd.dll

Bluetooth Extensions (Bthkd.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

The Bluetooth debugger extensions display information about the current Bluetooth environment on the target system.

Note As you work with the Bluetooth debugging extensions, you may come across undocumented behavior or APIs. We strongly recommend against taking dependencies on undocumented behavior or APIs as it's subject to change in future releases.

In this section

TOPIC	DESCRIPTION
!bthkd.bthdevinfo	The !bthkd.bthdevinfo command displays the information about a given BTHENUM created device PDO.
!bthkd.bthenuminfo	The !bthkd.bthenuminfo command displays information about the BTHENUM FDO.
!bthkd.bthinfo	The !bthkd.bthinfo command displays details about the BTHPORT FDO. This command is a good starting point for Bluetooth investigations as it displays address information that can be used to access many of the other Bluetooth debug extension commands.
!bthkd.bthhelp	The !bthkd.bthhelp command displays help for the Bluetooth debug extension commands.
!bthkd.bthtree	The !bthkd.bthtree command displays the complete Bluetooth device tree.
!bthkd.bthusbtransfer	The !bthkd.bthusbtransfer command displays the Bluetooth usb transfer context including Irp, Bip and transfer buffer information.
!bthkd.dibflags	The !bthkd.dibflags command displays DEVICE_INFO_BLOCK.DibFlags dumps flags set in _DEVICE_INFO_BLOCK.DibFlags.
!bthkd.hcicmd	The !bthkd.hcicmd command displays a list of the currently pending commands.
!bthkd.hciinterface	The !bthkd.hciinterface command displays the bthport!_HCI_INTERFACE structure.

TOPIC	DESCRIPTION
!bthkd.l2capinterface	The !bthkd.l2capinterface command displays information about the L2CAP interface.
!bthkd.rfcomminfo	The !bthkd.rfcomminfo command displays information about the RFCOMM FDO and the TDI Device Object.
!bthkd.rfcommconnection	The !bthkd.rfcommconnection command displays information about a given RFCOMM connection object.
!bthkd.rfcommchannel	The !bthkd.rfcommchannel command displays information about a given RFCOMM channel CB.
!bthkd.sdpinterface	The !bthkd.sdpinterface command displays information about the SDP interface.
!bthkd.scointerface	The !bthkd.scointerface command displays information about the SCO interface.
!bthkd.sdpnode	The !bthkd.sdpnode command displays information about a node in an sdp tree.
!bthkd.sdpstream	The !bthkd.sdpstream command displays the contents of a SDP stream.

GPIO Extensions

5/26/2017 • 1 min to read • [Edit Online](#)

The General Purpose Input/Output (GPIO) extension commands display the software state of GPIO controllers. These commands display information from data structures maintained by the GPIO framework extension driver (Msgpioclx.sys). For information about the GPIO framework extension, see [General-Purpose I/O \(GPIO\) Drivers](#).

The GPIO debugger extension commands are implemented in gpiokd.dll. To load the GPIO commands, enter **.load gpiokd.dll** in the debugger.

Each GPIO controller has a set of banks. Each bank has a pin table that has an array of pins. The GPIO debugger extension commands display information about GPIO controllers, banks, pin tables, and pins.

Data structures used by the GPIO commands

The GPIO debugger extension commands use these data structures, which are defined by Msgpioclx.sys.

msgpioclx!_DEVICE_EXTENSION

The device extension structure for the GPIO framework extension driver. This structure holds information about an individual GPIO controller.

msgpioclx!_GPIO_BANK_ENTRY

This structure holds information about an individual bank of a GPIO controller.

msgpioclx!_GPIO_PIN_INFORMATION_ENTRY

This structure holds information about an individual pin in a bank of a GPIO controller.

Getting started with GPIO debugging

To start debugging a GPIO issue, enter the [!gpiokd.clientlist](#) command. The [!gpiokd.clientlist](#) command displays an overview of all registered GPIO controllers and displays addresses that you can pass to other GPIO debugger commands.

In this section

TOPIC	DESCRIPTION
!gpiokd.help	The !gpiokd.help command displays help for the GPIO debugger extension commands.
!gpiokd.bankinfo	The !gpiokd.bankinfo command displays information about a GPIO bank.
!gpiokd.clientlist	The !gpiokd.clientlist command displays all registered GPIO controllers.
!gpiokd.gpioext	The !gpiokd.gpioext command displays information about a GPIO controller.

TOPIC	DESCRIPTION
!gpiokd.pininfo	The !gpiokd.pininfo command displays information about a specified GPIO pin.
!gpiokd.pinisrvec	The !gpiokd.pinisrvec command displays Interrupt Service Routine (ISR) vector information for a specified pin.
!gpiokd.pintable	The !gpiokd.pintable command displays information about an array of GPIO pins.

!gpiokd.bankinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gpiokd.bankinfo** command displays information about a GPIO bank.

```
!gpiokd.bankinfo BankAddress [Flags]
```

Parameters

BankAddress

Address of a [_GPIO_BANK_ENTRY](#) structure that represents a bank of a GPIO controller.

Flags

Flags that specify which information is displayed. This parameter is a bitwise OR of one or more of the following flags.

FLAG	DESCRIPTION
0x1	Displays the pin table.
0x2	Displays the Enable and Mask registers.
0x4	If bit 0 (0x1) is set and this flag (0x4) is set, the display includes unconfigured pins.

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gpiokd.gpioext** command displays information about a GPIO controller.

```
!gpiokd.gpioext ExtensionAddress [Flags]
```

Parameters

ExtensionAddress

Address of the [_DEVICE_EXTENSION](#) structure that represents the GPIO controller.

Flags

Flags that specify which information is displayed. This parameter is a bitwise OR of one or more of the following flags.

FLAG	DESCRIPTION
0x1	Displays the pin table for each bank.
0x2	If bit 0 (0x1) is set and this flag (0x2) is set, the display includes the Enable and Mask registers for each bank.
0x4	If bit 0 (0x1) is set and this flag (0x4) is set, the display includes unconfigured pins.

!gpiokd.pintable

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gpiokd.pintable** command displays information about an array of GPIO pins.

```
!gpiokd.pintable PinBase PinCount [Flags]
```

Parameters

PinBase

Address of an array of [_GPIO_PIN_INFORMATION_ENTRY](#) structures.

PinCount

The number of pins to display.

Flags

Flags that specify which information is displayed. This parameter is a bitwise OR of one or more of the following flags.

FLAG	DESCRIPTION
0x1	Not used by this command.
0x2	Not used by this command.
0x4	The display includes unconfigured pins.

USB 3.0 Extensions

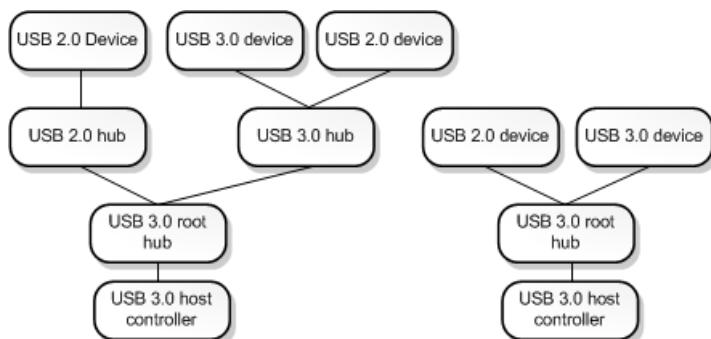

5/26/2017 • 2 min to read • [Edit Online](#)

This section describes the USB 3.0 debugger extension commands. These commands display information from data structures maintained by three drivers in the USB 3.0 stack: the USB 3.0 hub driver, the USB host controller extension driver, and the USB 3.0 host controller driver. For more information about these three drivers, see [USB Driver Stack Architecture](#). For an explanation of the data structures used by the drivers in the USB 3.0 stack, see [USB 3.0 Data Structures](#) and Part 2 of the [USB Debugging Innovations in Windows 8](#) video.

The USB 3.0 debugger extension commands are implemented in `Usb3kd.dll`. To load the `Usb3kd` commands, enter `.load usb3kd.dll` in the debugger.

USB 3.0 Tree

The USB 3.0 tree contains all USB 3.0 host controllers and all hubs and devices that are connected to USB 3.0 host controllers. The following diagram shows an example of a USB 3.0 tree.

The tree shown in the diagram has two USB 3.0 host controllers. Notice that not every device shown in the diagram is a USB 3.0 device. But all of the devices shown (including the hubs) are part of the USB 3.0 tree, because each device is on a branch that originates at a USB 3.0 host controller.

You can think of the diagram as two trees, one for each host controller. However, when we use the term *USB 3.0 tree*, we are referring to the set of all USB 3.0 host controllers along with their connected hubs and devices.

Getting started with USB 3.0 debugging

To start debugging a USB 3.0 issue, enter the `!usb_tree` command. The `!usb_tree` command displays a list of commands and addresses that you can use to investigate host controllers, hubs, ports, devices, endpoints, and other elements of the USB 3.0 tree.

Hub commands

The following extension commands display information about USB 3.0 hubs, devices, and ports. The displayed information is based on data structures maintained by the USB 3.0 hub driver.

- [!usb3kd.usb_tree](#)
- [!usb3kd.hub_info](#)
- [!usb3kd.hub_info_from_fdo](#)
- [!usb3kd.device_info](#)
- [!usb3kd.device_info_from_pdo](#)
- [!usb3kd.port_info](#)

UCX commands

The following extension commands display information about USB 3.0 host controllers, devices, and ports. The displayed information is based on data structures maintained by the USB host controller extension driver.

- [**!usb3kd.uxc_controller_list**](#)
- [**!usb3kd.uxc_controller**](#)
- [**!usb3kd.uxc_device**](#)
- [**!usb3kd.uxc_endpoint**](#)

Host controller commands

The following extension commands display information from data structures maintained by the USB 3.0 host controller driver.

- [**!usb3kd.xhci_dumpall**](#)
- [**!usb3kd.xhci_capability**](#)
- [**!usb3kd.xhci_commandring**](#)
- [**!usb3kd.xhci_deviceslots**](#)
- [**!usb3kd.xhci_eventring**](#)
- [**!usb3kd.xhci_registers**](#)
- [**!usb3kd.xhci_resourceusage**](#)
- [**!usb3kd.xhci_trb**](#)
- [**!usb3kd.xhci_transferring**](#)
- [**!usb3kd.xhci_findowner**](#)

Miscellaneous commands

- [**!usb3kd.usbdstatus**](#)
- [**!usb3kd.urb**](#)

[RCDRKD Extensions](#)

[Send comments about this topic to Microsoft](#)

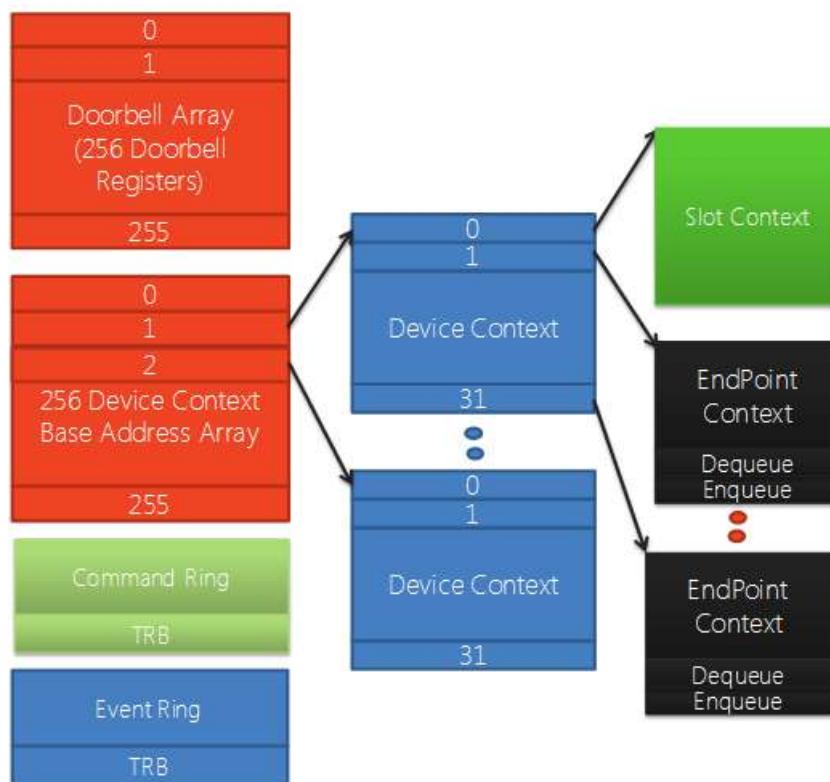

USB 3.0 Data Structures

5/26/2017 • 2 min to read • [Edit Online](#)

This topic describes the data structures used by the USB 3.0 host controller driver. Understanding these data structures will help you use the [USB 3.0](#) and [RCDRKD](#) debugger extension commands effectively. The data structures presented here have names that are consistent with the [USB 3.0 specification](#). Familiarity with the USB 3.0 specification will further enhance your ability to use the extension commands to debug USB 3.0 drivers.

The USB 3.0 host controller driver is part of the USB 3.0 core driver stack. For more information, see [USB Driver Stack Architecture](#).

Each USB 3.0 host controller can have up to 255 devices, and each device can have up to 31 endpoints. The following diagram shows some of the data structures that represent one host controller and the connected devices.

Device Context Base Array

The Device Context Base Array is an array of pointers to Device Context structures. There is one Device Context structure for each device connected to the host controller. Elements 1 through 255 point to Device Context structures. Element 0 points to a context structure for the host controller.

Device Context and Slot Context

A Device Context structure holds an array of pointers to Endpoint Context structures. There is one Endpoint Context structure for each endpoint on the device. Elements 1 through 31 point to Endpoint Context structures. Element 0 points to a Slot Context structure, which holds context information for the device.

Command Ring

The Command Ring is used by software to pass commands to the host controller. Some of these commands are

directed at the host controller, and some are directed at particular devices connected to the host controller.

Event Ring

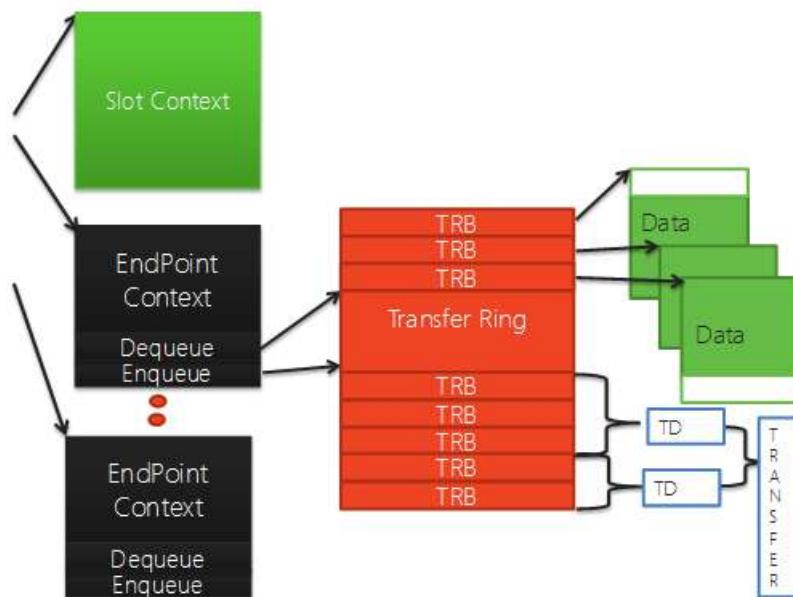

The Event Ring is used by the host controller to pass events to software. That is, the Event Ring is a structure that the host controller uses to inform drivers that an action has completed.

Doorbell Register Array

The Doorbell Register Array is an array of doorbell registers, one for each device connected to the host controller. Elements 1 through 255 are doorbell registers. Element 0 indicates whether there is a pending command in the Command Ring.

Software notifies the host controller that it has device-related or endpoint-related work to perform by writing context information into the doorbell register for the device.

The following diagram continues to the right of the preceding diagram. It shows additional data structures that represent a single endpoint.

Transfer Ring

Each endpoint has one or more Transfer Rings. A Transfer Ring is an array of Transfer Request Blocks (TRBs). Each TRB points to a block of contiguous data (up to 64 KB) that will be transferred between hardware and memory as a single unit.

When the USB 3.0 core stack receives a transfer request from a USB client driver, it identifies the Endpoint Context for the transfer, and then breaks the transfer request into one or more Transfer Descriptors (TDs). Each TD contains one or more TRBs.

Endpoint Context

An Endpoint Context structure holds context information for a single endpoint. It also has **Dequeue** and **Enqueue** members, which are used to track where TRBs are being consumed by the hardware and where TRBs are being added by software.

!usb3kd.help

5/26/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.help** command displays help for the USB 3 debugger extension commands.

DLL

Usb3kd.dll

See also

[USB 3.0 Extensions](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.device_info

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.device_info** command displays information about a USB device in the [USB 3.0 tree](#).

```
!usb3kd.device_info DeviceContext
```

Parameters

DeviceContext

Address of the _DEVICE_CONTEXT structure that represents the device.

DLL

Usb3kd.dll

Remarks

!device_info and **!lucx_device** both display information about a device, but the information displayed is different. The output of **!device_info** is from the point of view of the USB 3.0 hub driver, and the output of **!lucx_device** is from the point of view of the USB host controller extension driver. For example, the **!device_info** output includes information about configuration and interface descriptors, and **!lucx_device** output includes information about endpoints.

Examples

You can obtain the address of the device context structure by looking at the output of the [!usb_tree](#) command. In the following example, the address of the device context structure is 0xfffffa8005abd0c0.

```
3: kd> !usb_tree

## Dumping HUB Tree - !drvObj 0xfffffa800597f770
-----
Topology
-----
1) !xhci_info 0xfffffa80051d1940 ... - PCI: VendorId ...

[**!usb3kd.device_info_from_pdo**](#)

[Universal Serial Bus \(USB\) Drivers](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.device_info_from_pdo

5/31/2017 • 2 min to read • [Edit Online](#)

The **!usb3kd.device_info_from_pdo** command displays information about a USB device in the [USB 3.0 tree](#).

```
!usb3kd.device_info_from_pdo DeviceObject
```

Parameters

DeviceObject

Address of the physical device object (PDO) of a USB device or hub.

DLL

Usb3kd.dll

Remarks

!device_info_from_pdo and **!ucx_device** both display information about a device, but the information displayed is different. The output of **!device_info_from_pdo** is from the point of view of the USB 3.0 hub driver, and the output of **!ucx_device** is from the point of view of the USB host controller extension driver. For example, the **!device_info_from_pdo** output includes information about configuration and interface descriptors, and **!ucx_device** output includes information about endpoints.

Examples

You can get the address of the PDO from the output of [!usb_tree](#) or from a variety of other debugger commands. For example, the **!devnode** command displays the addresses of PDOs. In the following example, the USBSTOR device node is the direct child of the USBHUB3 node. The address of the PDO for the USBSTOR node is 0xfffffa80059c3800.

```
3: kd> !devnode 0 1 usbhub3

Dumping IopRootDeviceNode (= 0xfffffa8003609cc0)
DevNode 0xfffffa8005981730 for PDO 0xfffffa8004ffc550
  InstancePath is "USB\ROOT_HUB30\5&11db9684&0&0"
  ServiceName is "USBHUB3"
  State = DeviceNodeStarted (0x308)
  Previous State = DeviceNodeEnumerateCompletion (0x30d)

  DevNode 0xfffffa8005a546a0 for PDO 0xfffffa80059c3800
    InstancePath is "USB\VID_125F&PID_312A\0902100000000000342192873"
    ServiceName is "USBSTOR"
    State = DeviceNodeStarted (0x308)
    Previous State = DeviceNodeEnumerateCompletion (0x30d)

  DevNode 0xfffffa8005a09730 for PDO 0xfffffa8005b3a650
    InstancePath is "USBSTOR\Disk&Ven ..."
    ServiceName is "disk"
    State = DeviceNodeStarted (0x308)
    Previous State = DeviceNodeEnumerateCompletion (0x30d)
```

Now you can pass the address of the PDO to the **!usb3kd.device_info_from_pdo** command.

```
3: kd> !device_info_from_pdo 0xfffffa80059c3800
## Dumping Device Information fffffa80059c3800

!usb3kd.hub_info

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.device_info** command displays information about a hub in the **USB 3.0 tree**.

```
!usb3kd.hub_info DeviceExtension
```

Parameters

DeviceExtension

Address of the device extension for the hub's functional device object (FDO).

DLL

Usb3kd.dll

Examples

To obtain the address of the device extension, look at the output of the **!usb_tree** command. In the following example, the address of the device extension for the root hub is 0xfffffa8005ad92d0.

```
3: kd> !usb_tree
## Dumping HUB Tree - !drvObj 0xfffffa800597f770
-----
Topology
-----
1) !xhci_info 0xfffffa80051d1940 ... - PCI: VendorId 0x1033 ...
   !hub_info 0xfffffa8005ad92d0 (ROOT)
      !port_info 0xfffffa8005a5ca80 !device_info 0xfffffa8005b410c0 Desc: <none> Speed: High
      ...
```

Now you can pass the address of the device extension to the **!hub_info** command.

```
3: kd> !hub_info ffffffa8005ad92d0

## Dumping HUB Information ffffffa8005ad92d0

!usb3kd.hub_info_from_fdo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.hub_info_from_fdo** command displays information about a hub in the [USB 3.0 tree](#).

```
!usb3kd.hub_info_from_fdo DeviceObject
```

Parameters

DeviceObject

Address of the functional device object (FDO) that represents the hub.

DLL

Usb3kd.dll

Examples

You can get the address of the FDO from the output of [!usb_tree](#) or from a variety of other debugger commands. For example, the [!devstack](#) command displays the address of the FDO. In the following example, the address of the FDO is ffffffa800597a660.

```
3: kd> !devnode 0 1 ushubb3
Dumping IopRootDeviceNode (= 0xffffffa8003609cc0)

[USB 3.0 Extensions](#)

[Universal Serial Bus \(USB\) Drivers](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.uxc_device

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.uxc_device** extension displays information about a USB device in the **USB 3.0 tree**. The display is based on data structures maintained by the USB host controller extension driver (*UcxVersion.sys*).

```
!usb3kd.uxc_device UcxUsbDevicePrivContext
```

Parameters

UcxUsbDevicePrivContext

Address of the `_UCXUSBDEVICE_PRIVCONTEXT` structure that represents the device.

DLL

Usb3kd.dll

Remarks

The USB host controller extension driver (*UcxVersion.sys*) provides a layer of abstraction between the USB 3.0 hub driver and the USB 3.0 host controller driver. The extension driver has its own representation of host controllers, devices, and endpoints. The output the **!ucx_device** command is based on the data structures maintained by the extension driver. For more information about the USB host controller extension driver and the USB 3.0 host controller driver, see [USB Driver Stack Architecture](#).

!ucx_device and **!device_info** both display information about a device, but the information displayed is different. The output of **!ucx_device** is from the point of view of the USB host controller extension driver, and the output of **!device_info** is from the point of view of the USB 3.0 hub driver. For example, the **!ucx_device** output includes information about endpoints, and the **!device_info** output includes information about configuration and interface descriptors.

Examples

To obtain the address of the UCX USB device private context, look at the output of the **!ucx_controller_list** command. In the following example, the address of the private context for the second device is `0xfffffa8005bd9680`.

```
3: 3: kd> !ucx_controller_list

## Dumping List of UCX controller objects
-----
[1] !ucx_controller 0xfffffa80052da050 (dt ucx01000!_UCXCONTROLLER_PRIVCONTEXT fffffa80052da050)

!usb3kd.uxc_endpoint

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.uxc_endpoint** command displays information about an endpoint on a USB device in the [USB 3.0 tree](#). The display is based on data structures maintained by the USB host controller extension driver (*UcxVersion.sys*).

```
!usb3kd.uxc_endpoint UcxEndpointPrivContext
```

Parameters

UcxEndpointPrivContext

Address of the `_UCXENDPOINT_PRIVCONTEXT` structure that represents the endpoint.

DLL

Usb3kd.dll

Remarks

The USB host controller extension driver (*UcxVersion.sys*) provides a layer of abstraction between the USB 3.0 hub driver and the USB 3.0 host controller driver. The extension driver has its own representation of host controllers, devices, and endpoints. The output the **!ucx_endpoint** command is based on the data structures maintained by the extension driver. For more information about the USB host controller extension driver and the USB 3.0 host controller driver, see [USB Driver Stack Architecture](#).

Examples

To obtain the address of the UCX endpoint private context, look at the output of the **!ucx_controller_list** command. In the following example, the address of the private context for the first endpoint on the second device is `0xfffffa8003694860`.

```
3: kd> !ucx_controller_list

## Dumping List of UCX controller objects
-----

[**!usb3kd.uxc_controller_list**](#)

[Universal Serial Bus \(USB\) Drivers](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.ux_controller_list

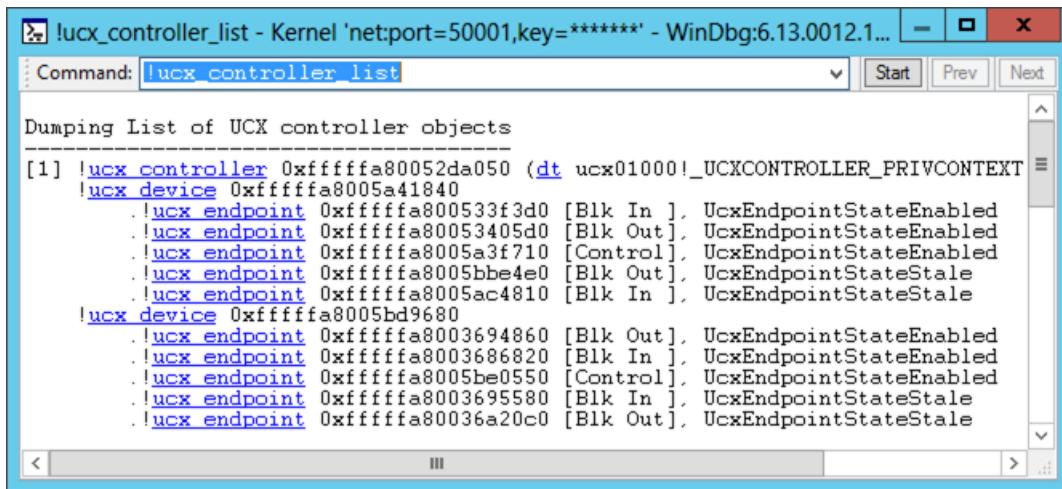

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.ux_controller_list** command displays information about all USB 3.0 host controllers on the computer. The display is based on data structures maintained by the USB host controller extension driver (UcxVersion.sys).

```
!usb3kd.ux_controller_list
```

Examples

The following screen shot show the output of the **!ucx_controller_list** command.

```
lucx_controller_list - Kernel 'net:port=50001,key=*****' - WinDbg:6.13.0012.1...
Command: !lucx_controller_list

Dumping List of UCX controller objects
[1] !lucx_controller 0xfffffa80052da050 (dt ucx01000!_UCXCONTROLLER_PRIVCONTEXT
  !lucx_device 0xfffffa8005a41840
    .!lucx_endpoint 0xfffffa800533f3d0 [Blk In], UcxEndpointStateEnabled
    .!lucx_endpoint 0xfffffa80053405d0 [Blk Out], UcxEndpointStateEnabled
    .!lucx_endpoint 0xfffffa8005a3f710 [Control], UcxEndpointStateEnabled
    .!lucx_endpoint 0xfffffa8005bbe4e0 [Blk Out], UcxEndpointStateStale
    .!lucx_endpoint 0xfffffa8005ac4810 [Blk In], UcxEndpointStateStale
  !lucx_device 0xfffffa8005bd9680
    .!lucx_endpoint 0xfffffa8003694860 [Blk Out], UcxEndpointStateEnabled
    .!lucx_endpoint 0xfffffa8003686820 [Blk In], UcxEndpointStateEnabled
    .!lucx_endpoint 0xfffffa8005be0550 [Control], UcxEndpointStateEnabled
    .!lucx_endpoint 0xfffffa8003695580 [Blk In], UcxEndpointStateStale
    .!lucx_endpoint 0xfffffa80036a20c0 [Blk Out], UcxEndpointStateStale
```

The output shows that there is one USB 3.0 host controller, which is represented by the line that begins with **!lucx_controller**. You can see that two devices are connected to the controller and that each device has four endpoints.

The output uses [Using Debugger Markup Language \(DML\)](#) to provide links. The links execute commands that give detailed information about individual devices or endpoints. For example, you could get detailed information about an endpoint by clicking one of the **!lucx_endpoint** links. As an alternative to clicking a link, you can enter a command. For example, to see information about the first endpoint of the second device, you could enter the command **!lucx_endpoint 0xfffffa8003694860**.

Note The DML feature is available in WinDbg, but not in Visual Studio or KD.

DLL

Usb3kd.dll

Remarks

The **!lucx_controller_list** command is the parent command for this set of commands.

- **!lucx_controller**
- **!lucx_device**
- **!lucx_endpoint**

The USB host controller extension driver (`UcxVersion.sys`) provides a layer of abstraction between the USB 3.0 hub driver and the USB 3.0 host controller driver. The extension driver has its own representation of host controllers, devices, and endpoints. The outputs of the commands in the **`!ucx_controller_list`** family are based on the data structures maintained by the extension driver. For more information about the USB host controller extension driver and the USB 3.0 host controller driver, see [USB Driver Stack Architecture](#). For an explanation of the data structures used by the drivers in the USB 3.0 stack, see Part 2 of the [USB Debugging Innovations in Windows 8](#) video.

!usb3kd.usbanalyze

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.usbanalyze** extension analyzes a USB 3.0 bug check.

```
!usb3kd.usbanalyze [-v]
```

Parameters

-v

The display is verbose.

DLL

Usb3kd.dll

!usb3kd.usbdstatus

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.usbdstatus** extension displays the name of a USBD status code.

```
!usb3kd.uxc_usbdstatus UrbStatus
```

Parameters

UsbdStatus

The numeric value of a USBD status code.

DLL

Usb3kd.dll

Remarks

USBD status codes are defined in Usb.h.

Examples

The following example passes the numeric value 0x80000200 to the **!usb3kd.usbdstatus** command. The command returns the name of the status code, USBD_STATUS_INVALID_URB_FUNCTION.

```
3: kd> !usb3kd.usbdstatus 0x80000200
USBD_STATUS_INVALID_URB_FUNCTION (0x80000200)
```

!usb3kd.usb_tree

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.usb_tree** extension displays information, in tree format, about all USB 3.0 controllers, hubs, and devices on the computer.

```
!usb3kd.usb_tree [1]
```

Parameters

1

The display includes status information for hubs and ports.

Examples

The following screen shot shows the output of the **!usb_tree** command.

```
!usb_tree - Kernel 'net:port=50001,key=*****' - WinDbg:6.13.0012.1424 ...
Command: !usb_tree
Topology
1) !xhci_info 0xfffffa80051fb3e0 ... - PCI: VendorId ... DeviceId
   !hub_info 0xfffffa8005928630 (ROOT)
      !port_info 0xfffffa80051e80c0 !device_info 0xfffffa8004630690 Desc
      !port_info 0xfffffa80049f30c0 <free>
      !port_info 0xfffffa800590fa80 <free>
      !port_info 0xfffffa800596aa80 !device_info 0xfffffa80046270c0 Desc
Enumerated Device List
1) !device_info 0xfffffa8004630690, !devstack fffffa800468a670
   Current Device State: ConfiguredInD0
   Desc: <none>
   USB\VID_ ...
   !ucx_device 0xfffffa8004425470 !xhci_deviceslots 0xfffffa80051fb3e0 1
2) !device_info 0xfffffa80046270c0, !devstack fffffa8003faf220
   Current Device State: ConfiguredInD0
   Desc: ...
   USB\VID_ ...
   !ucx_device 0xfffffa8003c46680 !xhci_deviceslots 0xfffffa80051fb3e0 3
Enumerated HUB List
1) Root HUB
   Hub PDO: 0xfffffa8005848800, PDO: 0xfffffa80051eb060, Depth 0
   !hub_info 0xfffffa8005928630
   Current Hub State: ConfiguredWithIntTransfer
```

The output shows that there is one USB 3.0 host controller, which is represented by the line that begins with **!xhci_info**. The next line represents the root hub for the host controller. The next four lines represent ports associated with the root hub. You can see that two ports have devices connected.

The output uses [Using Debugger Markup Language \(DML\)](#) to provide links. The links execute commands that give detailed information about individual objects in the tree. For example, you could get information about one of the connected devices by clicking one of the **!device_info** links. As an alternative to clicking a link, you can enter a command. For example, to see information about the first connected device, you could enter the command **!device_info 0xfffffa8004630690**.

Note The DML feature is available in WinDbg, but not in Visual Studio or KD.

DLL

Usb3kd.dll

Remarks

The **!usb_tree** command is the parent command for this set of commands.

- **!hub_info**
- **!hub_info_from_fdo**
- **!device_info**
- **!device_info_from_pdo**
- **!port_info**

The information displayed by the **!usb_tree** family of commands is based on data structures maintained by the USB 3.0 hub driver. For information about the USB 3.0 hub driver and other drivers in the USB 3.0 stack, see [USB Driver Stack Architecture](#). For an explanation of the data structures used by the drivers in the USB 3.0 stack, see Part 2 of the [USB Debugging Innovations in Windows 8](#) video.

!usb3kd.xhci_capability

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.xhci_capability** extension displays the capabilities of a USB 3.0 host controller.

```
!usb3kd.xhci_capability DeviceExtension
```

Parameters

DeviceExtension

Address of the device extension for the host controller's functional device object (FDO).

DLL

Usb3kd.dll

Remarks

The output the **!xhci_capability** command is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys). For more information about the USB 3.0 host controller driver and other drivers in the USB stack, see [USB Driver Stack Architecture](#).

Examples

To obtain the address of the device extension, look at the output of the **!xhci_dumpall** command. In the following example, the address of the device extension is 0xfffffa800536e2d0.

```
3: kd> !xhci_dumpall

## Dumping all the XHCI controllers - DrvObj 0xfffffa80053072f0
-----
1) ... - PCI: VendorId ... DeviceId ... RevisionId ... Firmware ...

!usb3kd.xhci_commandring

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.xhci_commandring** extension displays information about the command ring data structure associated with a USB 3.0 host controller.

```
!usb3kd.xhci_commandring DeviceExtension
```

Parameters

DeviceExtension

AAddress of the device extension for the host controller's functional device object (FDO).

DLL

Usb3kd.dll

Remarks

The output the **!xhci_commandring** command is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys). For more information about the USB 3.0 host controller driver and other drivers in the USB stack, see [USB Driver Stack Architecture](#).

The command ring is a data structure used by the USB 3.0 host controller driver to pass commands to the host controller.

Examples

To obtain the address of the device extension, look at the output of the **!xhci_dumpall** command. In the following example, the address of the device extension is 0xfffffa800536e2d0.

```
3: kd> !xhci_dumpall

## Dumping all the XHCI controllers - DrvObj 0xfffffa80053072f0

[Universal Serial Bus \(USB\) Drivers](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.xhci_deviceslots

5/31/2017 • 2 min to read • [Edit Online](#)

The **!usb3kd.xhci_deviceslots** extension displays information about the devices connected to a USB 3.0 host controller.

```
!usb3kd.xhci_deviceslots DeviceExtension [SlotNumber] [verbose]
```

Parameters

DeviceExtension

Address of the device extension for the host controller's functional device object (FDO).

SlotNumber

Slot number of the device to be displayed. If this parameter is omitted, all devices are displayed.

verbose

The display is verbose.

DLL

Usb3kd.dll

Remarks

The output the **!xhci_deviceslots** command is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys). For more information about the USB 3.0 host controller driver and other drivers in the USB stack, see [USB Driver Stack Architecture](#).

The USB 3.0 host controller driver maintains a list of data structures that represent the devices connected to the controller. Each of these data structures is identified by a slot number.

Examples

To obtain the address of the device extension, look at the output of the **!xhci_dumpall** command. In the following example, the address of the device extension is 0xfffffa800536e2d0.

```
3: kd> !xhci_dumpall
## Dumping all the XHCI controllers - DrvObj 0xfffffa80053072f0

[**!xhci_dumpall**](#)

[Universal Serial Bus \(USB\) Drivers](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.xhci_dumpall

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.xhci_dumpall** command displays information about all USB 3.0 host controllers on the computer. The display is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys).

```
!usb3kd.xhci_dumpall [1]
```

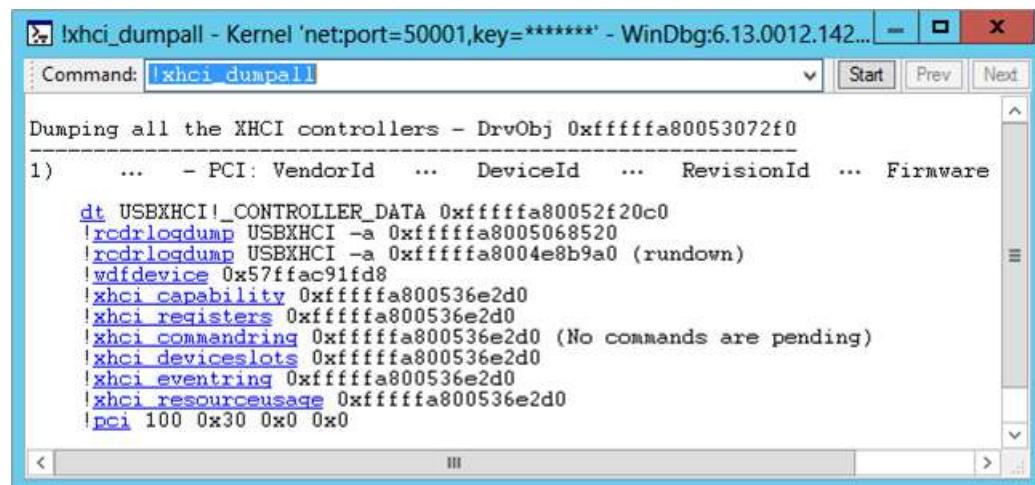

Parameters

1

Runs all of the XHCI commands and displays the output of each command.

Examples

The following screen shot show the output of the **!xhci_dumpall** command.

```
Dumping all the XHCI controllers - DrvObj 0xfffffa80053072f0
1) ... - PCI: VendorId ... DeviceId ... RevisionId ... Firmware
   dt USBXHCI!_CONTROLLER_DATA 0xfffffa80052f20c0
   !rcdrloqdump USBXHCI -a 0xfffffa8005068520
   !rcdrloqdump USBXHCI -a 0xfffffa8004e8b9a0 (rundown)
   !wdfdevice 0x57ffac91fd8
   !xhci_capability 0xfffffa800536e2d0
   !xhci_registers 0xfffffa800536e2d0
   !xhci_commandring 0xfffffa800536e2d0 (No commands are pending)
   !xhci_deviceslots 0xfffffa800536e2d0
   !xhci_eventring 0xfffffa800536e2d0
   !xhci_resourceusage 0xfffffa800536e2d0
   !pci 100 0x30 0x0 0x0
```

The output shows that there is one USB 3.0 host controller.

The output uses [Using Debugger Markup Language \(DML\)](#) to provide links. The links execute commands that give detailed information about the state of the host controller as it is maintained by the USB 3.0 host controller driver. For example, you could get detailed information about the host controller capabilities by clicking the **!xhci_capability** link. As an alternative to clicking a link, you can enter a command. For example, to see information about the host controller's resource usage, you could enter the command **!xhci_resourceusage 0xfffffa800536e2d0**.

Note The DML feature is available in WinDbg, but not in Visual Studio or KD.

DLL

Usb3kd.dll

Remarks

The **!xhci_dumpall** command is the parent command for this set of commands.

- **!xhci_capability**

- [!xhci_info](#)
- [!xhci_deviceslots](#)
- [!xhci_commandring](#)
- [!xhci_eventring](#)
- [!xhci_transferring](#)
- [!xhci_trb](#)
- [!xhci_registers](#)
- [!xhci_resourceusage](#)

The information displayed by the **!xhci_dumpall** family of commands is based on data structures maintained by the USB 3.0 host controller driver. For information about the USB 3.0 host controller driver and other drivers in the USB 3.0 stack, see [USB Driver Stack Architecture](#). For an explanation of the data structures used by the drivers in the USB 3.0 stack, see Part 2 of the [USB Debugging Innovations in Windows 8](#) video.

[Universal Serial Bus \(USB\) Drivers](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.xhci_eventring

5/31/2017 • 2 min to read • [Edit Online](#)

The **!usb3kd.xhci_eventring** extension displays information about the event ring data structure associated with a USB 3.0 host controller.

```
!usb3kd.xhci_eventring DeviceExtension
```

Parameters

DeviceExtension

Address of the device extension for the host controller's functional device object (FDO).

DLL

Usb3kd.dll

Remarks

The output **!xhci_eventring** command is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys). For more information about the USB 3.0 host controller driver and other drivers in the USB stack, see [USB Driver Stack Architecture](#).

The event ring is a structure used by the USB 3.0 host controller to inform drivers that an action has completed.

Examples

To obtain the address of the device extension, look at the output of the **!xhci_dumpall** command. In the following example, the address of the device extension is 0xfffffa800536e2d0.

```
3: kd> !xhci_dumpall
## Dumping all the XHCI controllers - DrvObj 0xfffffa80053072f0
-----
1) ... - PCI: VendorId ... DeviceId ... RevisionId ... Firmware ...
   dt USBXHCI!_CONTROLLER_DATA 0xfffffa80052f20c0
   !rcdrlogdump USBXHCI -a 0xfffffa8005068520
   !rcdrlogdump USBXHCI -a 0xfffffa8004e8b9a0 (rundown)
   !wdfdevice 0x57ffac91fd8
   !xhci_capability 0xfffffa800536e2d0
   !xhci_registers 0xfffffa800536e2d0
   !xhci_commandring 0xfffffa800536e2d0 (No commands are pending)
   !xhci_deviceslots 0xfffffa800536e2d0
   !xhci_eventring 0xfffffa800536e2d0
   ...
```

Now you can pass the address of the device extension to the **!xhci_eventring** command.

```

3: kd> !xhci_eventring 0xfffffa800536e2d0

!xhci_findowner

5/31/2017 • 3 min to read • [Edit Online](#)

The **!usb3kd.xhci_findowner** command finds the owner a common buffer.

```
!usb3kd.xhci_findowner Address
```

Parameters

Address

Virtual or physical address of a common buffer.

DLL

Usb3kd.dll

Remarks

A common buffer is a block of physically contiguous memory that's addressable by hardware. The USB 3.0 driver stack uses common buffers to communicate with USB 3.0 host controllers. Suppose the system crashes, and you come across an address that you suspect might be common buffer memory. If the address is common buffer memory, this command tells you which USB 3.0 host controller the memory belongs to (in case you have more than one USB 3.0 controller) and what the memory is used for.

Examples

The following example calls **!xhci_resourceusage** to list the addresses of some common buffers.

```
0: kd> !usb3kd.xhci_resourceusage 0x867fbfff

## Dumping CommonBuffer Resources
-----
dt USBHCI!_COMMON_BUFFER_DATA 0x868d61c0

!xhci_info 0x867fbff0 Texas Instruments - PCI: VendorId 0x104c DeviceId 0x8241 RevisionId 0x02

dt _TRACKING_DATA 0x868d69d4 VA 0x868e4400 LA 0xdb2e4400 -- Owner 0x86801488 Tag: Cmd1 Size 512

dt _COMMAND_DATA 0x86801488
!xhci_commandring 0x867fbff0 <-- This memory is used for command ring.

```

The **!xhci_findowner** command is especially useful when you have an address in a transfer request block (TRB), and you want to track it back to the device slot that it belongs to. In the following example, one of the addresses listed in the output of **!xhci_transferring** is 0xda452230, which is the physical address of a TRB. The example passes that address to **!xhci_findowner**. The output shows that the TRB belongs to device slot 8 (**!xhci_deviceslots 0x8551d370 8**).

```

0: kd> !usb3kd.xhci_transferring 0x87652200

!usb3kd.xhci_info

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usb3kd.xhci_info** extension displays all the XHCI commands for an individual USB 3.0 host controller.

```
!usb3kd.xhci_info DeviceExtension
```

Parameters

DeviceExtension

Address of the device extension for the host controller's functional device object (FDO).

DLL

Usb3kd.dll

Remarks

The output the **!usb3kd.xhci_info** command is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys). For more information about the USB 3.0 host controller driver and other drivers in the USB stack, see [USB Driver Stack Architecture](#).

Examples

You can get address of the device extension from the **!xhci_dumpall** command or from a variety of other debugger commands. For example, the **!devstack** command displays the address of the device extension. In the following example, the address of the device extension for the host controller's FDO is ffffffa800536e2d0.

```
3: kd> !devnode 0 1 usbxhci
Dumping IopRootDeviceNode (= 0xfffffa8003609cc0)
DevNode 0xfffffa8003df3010 for PDO 0xfffffa8003dd5870
  InstancePath is "PCI\VEN_...
  ServiceName is "USBXHCI"
  ...

3: kd> !devstack 0xfffffa8003dd5870
  !DevObj  !DrvObj          !DevExt  ObjectName
  ffffffa800534b060  \Driver\USBXHCI  ffffffa800536e2d0  USBFDO-3
  ffffffa8003db5790  \Driver\ACPI    ffffffa8003701cb0
  > ffffffa8003dd5870  \Driver\pci    ffffffa8003dd59c0  NTPNP_PCI0020
  ...
```

Now you can pass the address of the device extension to the **!xhci_info** command.

```
3: kd> !xhci_info 0xfffffa80`0536e2d0

The **!usb3kd.xhci_trb** extension displays one or more transfer request blocks (TRBs) used by a USB 3.0 host controller

```
!usb3kd.xhci_trb VirtualAddress Count
!usb3kd.xhci_trb PhysicalAddress Count 1
```

Parameters

VirtualAddress

Virtual address of a TRB.

PhysicalAddress

Physical address of a TRB.

Count

The number of consecutive TRBs to display, starting at *VirtualAddress* or *PhysicalAddress*.

1

Specifies that the address is a physical address.

DLL

Usb3kd.dll

Remarks

The output the **!xhci_trb** command is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys). For more information about the USB 3.0 host controller driver and other drivers in the USB stack, see [USB Driver Stack Architecture](#).

Examples

In the following example, **0x844d7c00** is the virtual address of a TRB. The **1** is the count, which specifies how many consecutive TRBs to display.

```

[Universal Serial Bus \(USB\) Drivers](#)

[Send comments about this topic to Microsoft](#)

!usb3kd.xhci_transferring

5/31/2017 • 2 min to read • [Edit Online](#)

The **!usb3kd.xhci_transferring** extension displays a transfer ring (used by a USB 3.0 host controller) until it detects a cycle bit change.

```
!usb3kd.xhci_transferring VirtualAddress
!usb3kd.xhci_transferring PhysicalAddress 1
```

Parameters

VirtualAddress

Virtual address of the transfer ring.

PhysicalAddress

Physical address of the transfer ring.

1

Specifies that the address is a physical address.

DLL

Usb3kd.dll

Remarks

The output of the **!xhci_transferring** command is based on the data structures maintained by the USB 3.0 host controller driver (UsbXhci.sys). For more information about the USB 3.0 host controller driver and other drivers in the USB stack, see [USB Driver Stack Architecture](#).

The transfer ring is a structure used by the USB 3.0 host controller driver to maintain a list of transfer request blocks (TRBs). This command takes the virtual or physical address of a transfer ring, but displays the physical address of the TRBs. This is done so the command can correctly traverse LINK TRBs.

Examples

To obtain the address of the transfer ring, look at the output of the **!xhci_deviceslots** command. In the following example, the virtual address of the transfer ring is 0xfffffa8005b2fe00.

```

3: kd> !usb3kd.xhci_deviceslots 0xfffffa800523a2d0

USB 2.0 Extensions

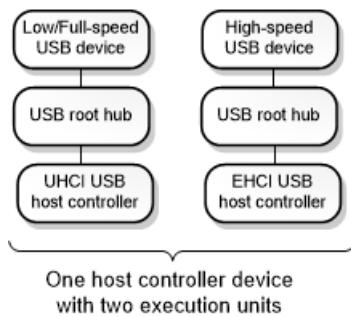

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the USB 2.0 debugger extension commands. These commands display information from data structures maintained by drivers in the USB 2.0 driver stack. For more information about these three drivers, see [USB Driver Stack Architecture](#).

The USB 2.0 debugger extension commands are implemented in Usbkd.dll. To load the Usbkd commands, enter **.load usbkd.dll** in the debugger.

USB 2.0 Tree

The USB 2.0 tree contains the device nodes that represent execution units on EHCI host controller devices along with the child nodes that represent hubs and connected devices. This diagram shows an example of a USB 2.0 tree.

The diagram shows one physical host controller device that has two execution units. Each execution unit appears as a device node in the Plug and Play device tree. One execution unit appears as a UHCI USB host controller node, and the other execution unit shows as an EHCI USB host controller node. Each of those nodes has a child node that represents a USB root hub. Each root hub has a single child node that represents a connected USB device.

Notice that the diagram is not a tree in the sense that not all nodes descend from a single parent node. However, when we use the term *USB 2.0 tree*, we are referring to the set of device nodes that represent execution units on EHCI host controller devices along with the nodes for hubs and connected devices.

Getting started with USB 2.0 debugging

To start debugging a USB 2.0 issue, enter the **!usb2tree** command. The **!usb2tree** command displays a list of commands and addresses that you can use to investigate host controllers, hubs, ports, devices, endpoints, and other elements of the USB 2.0 tree.

!usbkd._ehcidd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd._ehcidd** command displays information from a **usbehci!_DEVICE_DATA** structure.

```
!usbkd._ehcidd StructAddr
```

Parameters

StructAddr

Address of a **usbehci!_DEVICE_DATA** structure. To find addresses of **usbehci!_DEVICE_DATA** structures, use **!usbhcdext** or **!usbhcdlist**.

DLL

Usbkd.dll

Examples

Here is one way to get the address of a **usbehci!_DEVICE_DATA** structure. First enter **!usbkd.usbhcdlist**.

```
0: kd> !usbkd.usbhcdlist

MINIPORT List @ ffffff80001e5bbd0

## List of EHCI controllers

!drvobj fffffe00001fd33a0 dt USBPORT!_USBPORT_MINIPORT_DRIVER fffffe00001f48bd0 Registration Packet

!usbkd._ehciep

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd._ehciep** command displays information from a **usbehci!_ENDPOINT_DATA** structure. Use this command to display information about asynchronous endpoints (that is, control and bulk endpoints).

```
!usbkd._ehciep StructAddr
```

Parameters

StructAddr

Address of a **usbehci!_ENDPOINT_DATA** structure. To find addresses of **usbehci!_ENDPOINT_DATA** structures, use **!usbhcdext** and **!usblist**.

DLL

Usbkd.dll

Examples

This example shows one way to get the address of a **usbehci!_ENDPOINT_DATA** structure. Start with the **!usb2tree** command.

```
0: kd> !usbkd.usb2tree
...
2)!ehci_info fffffe0000206e1a0 !devobj fffffe0000206e050 PCI: VendorId 8086 DeviceId 293c RevisionId 0002

!usbkd._ehciregs

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd._ehciregs** command displays the operational and root hub port status registers of a USB EHCI host controller.

```
!usbkd._ehciregs StructAddr[, NumPorts]
```

Parameters

StructAddr

Address of a **usbehci!_HC_OPERATIONAL_REGISTER** structure. To find the address of a **usbehci!_HC_OPERATIONAL_REGISTER** structure, use **!usbkd.usbhcdlist**.

NumPorts

The number of root hub port status registers to display.

DLL

Usbkd.dll

Examples

Here is one way to get the address of a **usbehci!_HC_OPERATIONAL_REGISTER** structure. First enter **!usbkd.usbhcdlist**.

```
0: kd> !usbkd.usbhcdlist
MINIPORT List @ fffff80001e5b0d0

## List of EHCI controllers

!usbkd.isthisdumpasyncissue

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.isthisdumpasyncissue** command checks a crash dump file, generated by [Bug Check 0xFE](#), to see whether the likely cause of the crash was an Interrupt on Async Advance issue associated with a USB EHCI host controller.

```
!usbkd.isthisdumpasyncissue
```

DLL

Usbkd.dll

Remarks

Use this command only when you are debugging a crash dump file that was generated as a result of [Bug Check 0xFE: BUGCODE_USB_DRIVER](#).

Examples

Here is an example of the output of **!usbkd.isthisdumpasyncissue**.

```
1: kd> !analyze -v
*** ...
BUGCODE_USB_DRIVER (fe)
...
1: kd> !usbkd.isthisdumpasyncissue
This is *NOT* Async on Advance Issue because the EndPointData is NULL
```

!usbkd.urbfunc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.urbfunc** command displays the name of a URB function code.

```
!usbkd.urbfunc FunctionCode
```

Parameters

FunctionCode

The hexadecimal value of a URB function code. These codes are defined in usb.h.

DLL

Usbkd.dll

Examples

Here is an example of the output of **!urbfunc**.

```
0: kd> !usbkd.urbfunc 0xA
URB_FUNCTION_ISOCH_TRANSFER (0xA)
```

!usbkd.usb2

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usb2** command displays a list of USB endpoints that have USB 2.0 scheduling information.

```
!usbkd.usb2 DeviceExtension
```

Parameters

DeviceExtension

Address of the device extension for the functional device object (FDO) of a USB host controller.

DLL

Usbkd.dll

Examples

Here is one way to find the address of the device extension for the FDO of a USB host controller. First enter **!usbkd.usb2tree**.

```
0: kd> !usbkd.usb2tree

EHCI MINIPORT(s) dt usbport!_USBPORT_MINIPORT_DRIVER fffffe00001f48bd0

```

The output shows one EHCI execution unit and two UHCI execution units. The execution units shown in this example happen to be on a single USB host controller device. The output also shows the root hubs and connected devices.

The output uses [Using Debugger Markup Language \(DML\)](#) to provide links. The links execute commands that give detailed information related to objects in the tree. For example, you could click one of the [!devobj](#) links to get information about the functional device object associated with the EHCI execution unit. As an alternative to clicking the link, you could enter the command manually: **!devobj fffffe00001ca7050**

Note The DML feature is available in WinDbg, but not in Visual Studio or KD.

DLL

Usb3kd.dll

Remarks

The **!usb2tree** command is the parent command for many of the [USB 2.0 debugger extensions commands](#). The information displayed by these commands is based on data structures maintained by these drivers:

- usbehci.sys (miniport driver for USB 2 host controller)
- usbuhci.sys (miniport driver for USB 2 host controller)
- usbport.sys (port driver for USB 2 host controller)
- usbhub.sys (USB 2 hub driver)

For more information about these drivers, see [USB Driver Stack Architecture](#).

!usbkd.ehci_info_from_fdo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.ehci_info_from_fdo** command displays information about a USB host controller.

```
!usbkd.ehci_info_from_fdo fdo
```

Parameters

fdo

Address of the functional device object (FDO) of a UHCI or EHCI USB host controller. You can get the address of the FDO from the output of the **!usb2tree** command.

DLL

Usbkd.dll

Examples

First use the **!usb2tree** command to get the address of the FDO.

```
0: kd> !usbkd.usb2tree

EHCI MINIPORT(s) dt usbport!_USBPORT_MINIPORT_DRIVER fffffe00001f48bd0

!usbkd.usbhcext

5/31/2017 • 2 min to read • [Edit Online](#)

The **!usbkd.usbhcext** command displays information from the device extension of a USB host controller or a USB root hub.

```
!usbkd.usbhcext DeviceExtension
```

Parameters

DeviceExtension

Address of one of the following:

- The device extension for the functional device object (FDO) of a USB host controller.
- The device extension for the physical device object (PDO) a USB root hub.

DLL

Usbkd.dll

Examples

Here is one way to find the address of the device extension for the FDO of an EHCI host controller. First enter **!usbkd.usb2tree**.

```
0: kd> !usbkd.usb2tree

EHCI MINIPORT(s) dt usbport!_USBPORT_MINIPORT_DRIVER fffffe00001f48bd0

1)!ehci_info fffffe00001ca11a0 !devobj fffffe00001ca1050 PCI: VendorId 8086 DeviceId 293c RevisionId 0002
...
```

In the preceding output, the address of the device extension of the FDO is displayed as the argument of the [DML](#) command **!ehci_info fffffe00001ca11a0**.

Now pass the address of the device extension to the **!usbhcext** command.

```

!usbkd.usbhcdlog

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhcdlog** command displays a portion of the debug log for a USB host controller.

```
!usbkd.usbhcdlog DeviceExtension[, NumberOfEntries]
```

Parameters

DeviceExtension

Address of the device extension for the functional device object (FDO) of a UHCI or EHCI USB host controller.

NumberOfEntries

The number of log entries to display. To display the entire log, set this parameter to -1.

DLL

Usbkd.dll

Examples

Here is one way to find the address of the device extension for the FDO of a USB host controller. First enter

!usbkd.usb2tree.

```
0 kd> !usbkd.usb2tree

EHCI MINIPORT(s) dt usbport!_USBPORT_MINIPORT_DRIVER fffffe00001f48bd0

!usbkd.usbhcdpnp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhcdpnp** command displays the Plug and Play (PnP) state history for a USB host controller or root hub.

```
!usbkd.usbhcdpnp DeviceExtension
```

Parameters

DeviceExtension

Address of one of the following:

- The device extension for the functional device object (FDO) of a USB host controller.
- The device extension for the physical device object (PDO) a USB root hub.

DLL

Usbkd.dll

Examples

Here is one way to find the address of the device extension for the FDO of USB host controller. First enter [!usbkd.usb2tree](#).

```
0: kd> !usbkd.usb2tree

UHCI MINIPORT(s) dt usbport!_USBPORT_MINIPORT_DRIVER fffffe0000090c3d0
...
4)!uhci_info fffffe00001c8f1a0 !devobj fffffe00001c8f050 PCI: VendorId 8086 DeviceId 2938 RevisionId 0002
...
```

In the preceding output, the address of the device extension of the FDO is displayed as the argument of the [DML](#) command **!uhci_info fffffe00001c8f1a0**.

Now pass the address of the device extension to the **!usbhcdpnp** command.

```
0: kd> !usbkd.usbhcdpnp fffffe00001c8f1a0

## PNP STATE LOG (latest at bottom)

##      EVENT          STATE          NEXT
[01]  EvFDO_IRP_MN_START_DEVICE    PnpNotStarted    PnpStarted
[02]  EvFDO_IRP_MN_QBR_RH        PnpStarted      PnpStarted
```

Here is one way to find the address of the device extension for the PDO of a root hub. First enter [!usbkd.usb2tree](#).

```
4)!uhci_info fffffe00001c8f1a0 !devobj fffffe00001c8f050 PCI: VendorId 8086 DeviceId 2938 RevisionId 0002
RootHub !hub2_info fffffe00000d941a0 !devstack fffffe00000d94050
```

In the preceding output, you can see the address of the FDO of the root hub displayed as the argument to the command **!devstack fffffe00000d94050**. Use the [!devstack](#) command to find the address of the PDO and the PDO device extension.

```
0: kd> !kdexts.devstack fffffe00000d94050
!DevObj          !DrvObj          !DevExt          ObjectName
> fffffe00000d94050  \Driver\usbhub  fffffe00000d941a0  0000006b
fffffe00000ed4050  \Driver\usbuhci  fffffe00000ed41a0  USBPDO-2
```

In the preceding output, you can see that the address of the device extension for the PDO of the root hub is [fffffe00000ed41a0](#).

Now pass the address of the device extension to the **!usbhcdpnp** command.

```
0: kd> !usbkd.usbhcdpnp fffffe00000ed41a0

!usbkd.usbhcdpow

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhcdpow** command displays the power state history for a USB host controller or root hub.

```
!usbkd.usbhcdpow DeviceExtension
```

Parameters

DeviceExtension

Address of one of the following:

- The device extension for the functional device object (FDO) of a USB host controller.
- The device extension for the physical device object (PDO) a USB root hub.

DLL

Usbkd.dll

Examples

Here is one way to find the address of the device extension for the FDO of an EHCI host controller. First enter

!usbkd.usb2tree.

```
0: kd> !usbkd.usb2tree
...
2)!ehci_info fffffe00001ca11a0 !devobj fffffe00001ca1050 PCI: VendorId 8086 DeviceId 293c RevisionId 0002
...
```

In the preceding output, the address of the device extension of the FDO is displayed as the argument of the [DML](#) command **!ehci_info fffffe00001ca11a0**.

Now pass the address of the device extension to the **!usbhcdpow** command.

```

0: kd> !usbkd.usbhcdpow fffffe00001ca11a0

dt USBPORT!_FDO_EXTENSION fffffe00001ca15a0

# !usbkd.usbhublog

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhublog** command displays the debug log for a USB hub.

```
!usbkd.usbhublog DeviceExtension[, NumberOfEntries]
```

## Parameters

### *DeviceExtension*

Address of the device extension for the functional device object (FDO) of a USB hub.

### *NumberOfEntries*

The number of log entries to display. To display the entire log, set this parameter to -1.

## DLL

Usbkd.dll

## Examples

Here is one way to find the address of the device extension for the FDO of a USB hub. First enter **!usbkd.usb2tree**.

```
0: kd> !usbkd.usb2tree
...
2:!ehci_info fffffe00001ca11a0 !devobj fffffe00001ca1050 PCI: VendorId 8086 DeviceId 293c RevisionId 0002
 RootHub !hub2_info fffffe000023201a0 !devstack fffffe00002320050
 ...
...
```

In the preceding output, you can see the suggested command **!devstack fffffe00002320050**. Enter this command.

```
0: kd> !kdexts.devstack fffffe00002320050

 !DevObj !DrvObj !DevExt ObjectName
 > fffffe00002320050 \Driver\usbhub fffffe000023201a0 0000002d
 fffffe0000213c050 \Driver\usbehci fffffe0000213c1a0 USBPDO-3
 ...
...
```

In the preceding output, **fffffe000023201a0** is the address of the device extension for the FDO of the hub.

Now pass the address of the device extension to **!usbhublog**. In this example, the second argument limits the display to 10 log entries.

```
0: kd> !usbkd.usbhublog fffffe000023201a0, 10

# !usbkd.usbhubmddevext

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhubmddevext** command displays a **usbhub!\_DEVICE\_EXTENSION\_HUB** structure if one is present in a crash dump that was generated as a result of a **Bug Check 0xFE**.

```
!usbkd.usbhubmddevext
```

## DLL

Usbkd.dll

## Remarks

Use this command only when you are debugging a crash dump file that was generated as a result of **Bug Check 0xFE: BUGCODE\_USB\_DRIVER**.

## See also

[USB 2.0 Debugger Extensions](#)

# !usbkd.usbhubmdpd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhubmdpd** command displays a **usbhub!\_HUB\_PORT\_DATA** structure if one is present in a crash dump that was generated as a result of [Bug Check 0xFE](#).

```
!usbkd.usbhubmdpd [PortNum]
```

## Parameters

*PortNum*

A USB port number. If you specify a port number, this command displays the structure (if one is present) that represents the specified port. If you do not specify a port number, this command displays the structure (if one is present) on which [Bug Check 0xFE](#) was initiated.

## DLL

Usbkd.dll

## Remarks

Use this command only when you are debugging a crash dump file that was generated as a result of [Bug Check 0xFE: BUGCODE\\_USB\\_DRIVER](#).

# !usbkd.usbhubpd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhubpd** command displays information about a USB port.

```
!usbkd.usbhubpd StructAddr
```

## Parameters

*StructAddr*

Address of a **usbhub!\_HUB\_PORT\_DATA** structure. To get the addresses of these structures, use **!usbhubext**.

## DLL

Usbkd.dll

## Examples

Here is one way to find the address of a **usbhub!\_HUB\_PORT\_DATA**. First enter **!usbkd.usb2tree**.

```
0: kd> !usbkd.usb2tree
...
2)!ehci_info fffffe00001ca11a0 !devobj fffffe00001ca1050 PCI: VendorId 8086 DeviceId 293c RevisionId 0002
 RootHub !hub2_info fffffe000023201a0 !devstack fffffe00002320050
 ...
...
```

In the preceding output, you can see the suggested command **!devstack fffffe00002320050**. Enter this command.

```
0: kd> !kdexts.devstack fffffe00002320050
 !DevObj !DrvObj !DevExt ObjectName
 > fffffe00002320050 \Driver\usbhub fffffe000023201a0 0000002d
 fffffe0000213c050 \Driver\usbehci fffffe0000213c1a0 USBPDO-3
 ...
...
```

In the preceding output, you can see that the address of the device extension for the FDO of the hub is **fffffe000023201a0**.

Pass the address of the device extension to the **!usbhubext** command.

```

0: kd> !usbkd.usbhubext fffffe000023201a0

FDO fffffe00002320050 PDO fffffe0000213c050 HubNumber# 3

# !usbkd.usbhubs

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbhubs** command displays information about USB hubs.

```
!usbkd.usbhubs a[v]
!usbkd.usbhubs x[v]
!usbkd.usbhubs r[v]
```

## Parameters

**a**

Display all hubs.

**r**

Display root hubs.

**x**

Display external hubs.

**v**

The output is verbose. For example, **!usbhubs rv** displays verbose output about all root hubs.

## DLL

Usbkd.dll

## Examples

Here is an example of verbose output from the **!usbhubs** command.

```

0: kd> !usbkd.usbhubs rv

args 'rv'
level: r v

# !usbkd.usblist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usblist** command displays a linked list of structures of a specified type.

```
!usbkd.usblist ListAddr, ListType
```

## Parameters

### *ListAddr*

Address of a linked list of structures. To find addresses of linked lists maintained by the USB port driver, use **!usbhcdext**. To find addresses of linked list maintained by the USB hub driver, use **!usbhubext**.

### *ListType*

One of the following list types.

| LIST TYPE | STRUCTURE                               |
|-----------|-----------------------------------------|
| BC        | <b>usbport!_BUS_CONTEXT</b>             |
| EP        | <b>usbport!_HCD_ENDPOINT</b>            |
| TT        | <b>usbport!_TRANSACTION_TRANSLATOR</b>  |
| DL        | <b>usbport!_USBD_DEVICE_HANDLE</b>      |
| PL        | <b>usbhub!_DEVICE_EXTENSION_PDO</b>     |
| EL        | <b>usbhub!_HUB_EXCEPTION_RECORD</b>     |
| RL        | <b>usbhub!_HUB_REFERENCE_LIST_ENTRY</b> |
| TL        | <b>usbhub!_HUB_TIMER_OBJECT</b>         |
| WI        | <b>usbhub!_HUB_WORKITEM</b>             |
| IO        | <b>usbhub!_IO_LIST_ENTRY</b>            |
| LA        | <b>usbhub!_LATCH_LIST_ENTRY</b>         |
| CL        | <b>usbhub!_PORT_CHANGE_CONTEXT</b>      |
| BL        | <b>usbhub!_SSP_BUSY_HANDLE</b>          |

## DLL

Usbkd.dll

## Examples

Here is one way to find the address of a linked list. First enter [!usbkd.usb2tree](#).

```
0: kd> !usbkd.usb2tree
...
2)!ehci_info fffffe00001ca11a0 !devobj fffffe00001ca1050 ...
...
```

In the preceding output, the address of the device extension of the FDO is displayed as the argument of the DML command **!ehci\_info fffffe00001ca11a0**.

Either click the DML command or pass the address of the device extension to [!usbhcdext](#).

```
0: kd> !usbkd.usbhcdext fffffe00001ca11a0

HC Flavor 1000 FDO fffffe00001ca1050
Root Hub: FDO fffffe00002320050 !hub2_info fffffe000023201a0
...
DeviceHandleList: !usblist fffffe00001ca23b8, DL
...
```

In the preceding output, fffffe00001ca23b8 is the address of a linked list of [usbport!\\_USBD\\_DEVICE\\_HANDLE](#) structures.

Now pass the address of the linked list to [!usblist](#).

```
0: kd> !usblist fffffe00001ca23b8, DL
list: fffffe00001ca23b8 DL

!usbdevh fffffe000020f9590

# !usbkd.usbportmddcontext

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbportmddcontext** command displays USBPORT context data if it is present in a crash dump that was generated as a result of **Bug Check 0xFE**.

```
!usbkd.usbportmddcontext
```

## DLL

Usbkd.dll

## Remarks

Use this command only when you are debugging a crash dump file that was generated as a result of **Bug Check 0xFE: BUGCODE\_USB\_DRIVER**.

# !usbkd.usbtt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!usbkd.usbtt** command displays information from a **USBPORT!\_TRANSACTION\_TRANSLATOR** structure.

```
!usbkd.usbtt StructAddr
```

## Parameters

*StructAddr*

Address of a **usbport!\_TRANSACTION\_TRANSLATOR** structure. To get the transaction translator list for a USB host controller, use the **!usbkd.usbhcdext** command.

## DLL

Usbkd.dll

## Examples

Here is one way to find the address of a **usbport!\_TRANSACTION\_TRANSLATOR** structure. First enter **!usbkd.usb2tree**.

```
0: kd> !usbkd.usb2tree
...
2)!ehci_info fffffe00001ca11a0 !devobj fffffe00001ca1050 PCI: VendorId 8086 DeviceId 293c RevisionId 0002
...
```

In the preceding output, the address of the device extension of the FDO is displayed as the argument of the [DML](#) command **!ehci\_info fffffe00001ca11a0**.

Either click the DML command or pass the address of the device extension to **!usbhcdext** to get the address of [GlobalTtListHead](#). Pass that address to **!usbkd.usblist**, which will display addresses of **\_TRANSACTION\_TRANSLATOR** structures.

# RCDRKD Extensions

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the RCDRKD debugger extension commands. These commands display WPP trace messages created by drivers. Starting with Windows 8, you no longer need a separate trace message format (TMF) file to parse WPP messages. The TMF information is stored in the regular symbol file (PDB file).

Starting in Windows 10, kernel-mode and user-mode drivers can use [Inflight Trace Recorder \(IFR\) for logging traces](#). Your kernel-mode driver can use the RCDRKD commands to read messages from the circular buffers, format the messages, and display the messages in the debugger.

**Note** You cannot use the RCDRKD commands to view UMDF driver logs, UMDF framework logs, and KMDF framework logs. To view those logs, use [Windows Driver Framework Extensions \(Wdfkd.dll\)](#) commands.

The RCDRKD debugger extension commands are implemented in Rcdrkd.dll. To load the RCDRKD commands, enter `.load rcdrkd.dll` in the debugger.

The following two commands are the primary commands for displaying trace messages.

- [!rcdrkd.rcdrlogdump](#)
- [!rcdrkd.rcdrcrashdump](#)

The following auxiliary commands provide services related to displaying and saving trace messages.

- [!rcdrkd.rcdrloglist](#)
- [!rcdrkd.rcdrlogsave](#)
- [!rcdrkd.rcdrsearchpath](#)
- [!rcdrkd.rcdrsettraceprefix](#)
- [!rcdrkd.rcdrtmffile](#)
- [!rcdrkd.rcdrtraceprtdebug](#)

The [!rcdrkd.rcdrhelp](#) displays help for the RCDRKD commands in the debugger.

# !rcdrkd.rcdrcrashdump

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rcdrkd.rcdrcrashdump** extension is used with a minidump file to display the recorder log (if the log is present in the minidump).

```
!rcdrkd.rcdrcrashdump TraceProviderGuid
!rcdrkd.rcdrcrashdump DriverName
```

## Parameters

### *TraceProviderGuid*

GUID of the trace provider. This parameter must include braces: {*guid*}

### *DriverName*

The name of the driver. The driver name can be used instead of the trace provider GUID for drivers that use the Inflight Trace Recorder (IFR).

## DLL

Rcdrkd.dll

# !rcdrkd.rcdrlogdump

5/31/2017 • 2 min to read • [Edit Online](#)

The **!rcdrkd.rcdrlogdump** extension displays the trace messages from all recorder buffers of a driver or set of drivers.

```
!rcdrkd.rcdrlogdump DriverName [DriverName ...]
!rcdrkd.rcdrlogdump DriverName -a Address
```

## Parameters

### *DriverName*

The name of a driver, not including the .sys extension.

### *Address*

If Address is specified, this command displays the trace messages from the log buffer at the specified address.

## DLL

Rcdrkd.dll

## Examples

The following example shows a portion of the output of the **!rcdrlogdump** command.

```

3: kd> !rcdrlogdump usbhci.sys

# !rcdrkd.rcdrloglist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rcdrkd.rcdrloglist** extension displays a list of the recorder logs owned by a driver or a set of drivers.

```
!rcdrkd.rcdrloglist DriverName [DriverName ...]
```

## Parameters

### *DriverName*

The name of a driver, not including the .sys extension.

## DLL

Rcdrkd.dll

## Remarks

This command is relevant only for drivers that log messages to different logs by using the WppRecorder API.

## Examples

The following example displays a list of all recorder logs owned by the USB 3.0 host controller driver (usbxhci.sys).

```
3: kd> !rcdrloglist usbxhci
Log dump command Log ID Size

# !rcdrkd.rcdrlogsave

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rcdrkd.rcdrlogsave** extension saves the recorder buffers of a driver.

```
!rcdrkd.rcdrlogsave DriverName [CaptureFilename]
```

## Parameters

### *DriverName*

The name of the driver, not including the .sys extension.

### *CaptureFileName*

The name of the file (not including the .etl extension) in which to save the recorder buffers. If *CaptureFileName* is not specified, the recorder buffers are saved in *DriverName*.etl.

## DLL

Rcdrkd.dll

# !rcdrkd.rcdrsearchpath

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rcdrkd.rcdrsearchpath** extension sets the search path for trace message format (TMF) and trace message control (TMC) files.

```
!rcdrkd.rcdrsearchpath FilePath
```

## Parameters

### *FilePath*

Path to the format files.

## DLL

Rcdrkd.dll

## Remarks

The search path set by this command takes precedence over the search path specified in the TRACE\_FORMAT\_SEARCH\_PATH environment variable.

## See also

[RCDRKD Extensions](#)

[Send comments about this topic to Microsoft](#)

# !rcdrkd.rcdrsettraceprefix

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rcdrkd.rcdrsettraceprefix** extension sets the trace message prefix.

```
!rcdrkd.rcdrsettraceprefix TracePrefixString
```

## Parameters

*TracePrefixString*

The trace message prefix string.

## DLL

Rcdrkd.dll

## Remarks

Each message in a recorder log has a prefix that you can control by specifying a trace message prefix string. For more information, see [Trace Message Prefix](#).

## Examples

In the following example, the trace message prefix is originally **%7!u!: %!FUNC! -**. The parameter **%7!u!** specifies that the prefix includes the message sequence number. The parameter **%!FUNC!** specifies that the prefix includes the name of the function that generated the message. The example calls **!rcdrsettraceprefix** to change the prefix string to **%7!u!**. After that, the log display includes message sequence numbers, but does not include function names.

The **!rcdrkd.rcdrtmffile** extension sets or clears the name of the trace message format (TMF) file.

```
!rcdrkd.rcdrtmffile [Filename]
```

## Parameters

### *Filename*

The name of the TMF file. If this parameter is not specified, the filename is cleared.

## DLL

Rcdrkd.dll

## See also

# !rcdrkd.rcdrtraceprtdebug

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rcdrkd.rcdrtraceprtdebug** extension turns TracePrt diagnostic mode on or off. This extension should be used under the direction of support.

```
!rcdrkd.rcdrtraceprtdebug {on|off}
```

## Parameters

### on

Turns TracePrt diagnostic mode on.

### off

Turns TracePrt diagnostic mode off.

# HID Extensions

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the Human Interface Device (HID) debugger extension commands.

The HID debugger extension commands are implemented in Hidkd.dll. To load the HID commands, enter **.load hidkd.dll** in the debugger.

## Getting started with the HID extensions

To start debugging a HID issue, enter the **!hidtree** command. The **!hidtree** command displays a list of commands and addresses that you can use to investigate device objects, prepared HID data, and HID report descriptors.

## In this section

| TOPIC                          | DESCRIPTION                                                                                                                                                                                                                                        |

```

O

In this example, there are two device nodes that have a HID function driver. A functional device object (FDO) represents the HID driver in those two nodes. The first FDO node has two child nodes, and the second FDO node has one child node. In the debugger output, the child nodes have the PDO heading.

**Note** This set of device nodes does not form a tree that has a single root node. The device nodes that have HID function drivers can be isolated from each other.

When you are debugging a HID issue, the **!hidtree** is a good place to start, because the command displays several addresses that you can pass to other HID debugger commands. The output uses [Debugger Markup Language \(DML\)](#) to provide links. The links execute commands that give detailed information related to an individual device node. For example, you could get information about an FDO by clicking one of the **!hidfdo** links. As an alternative to clicking a link, you can enter a command. For example, to see detailed information about the

first node in the preceding output, you could enter the command **!devnode 0xffffe00003b18d30**.

**Note** The DML feature is available in WinDbg, but not in Visual Studio or KD.

# !hidkd.hidrd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!hidkd.hidrd** command displays a HID report descriptor in both raw and parsed format.

```
!hidkd.hidrd rd Length
```

## Parameters

*rd*

Address of the raw report descriptor data. To get the address of the descriptor data, use the **!hidfdo** command.

*Length*

The length, in bytes, of the raw report descriptor data. To get the length, use the **!hidfdo** command.

## DLL

Hidkd.dll

## Examples

This example shows how to use the **!hidfdo** command followed by the **!hidrd** command. The output of **!hidfdo** shows both the address and length of the raw report descriptor data.

# Logger Extensions (Logexts.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands related to the Logger and LogViewer tools can be found in Logexts.dll.

This DLL appears in the winext directory. It can be used with all Windows operating systems.

[Send comments about this topic to Microsoft](#)

# !logexts.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.help** extension displays a Help text in the Command Prompt window showing all Logexts.dll extension commands.

```
!logexts.help
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

[Send comments about this topic to Microsoft](#)

# !logexts.logb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.logb** extension displays or flushes the output buffer.

```
!logexts.logb p
!logexts.logb f
```

## Parameters

### **p**

Causes the contents of the output buffer to be displayed in the debugger.

### **f**

Flushes the output buffer to the disk.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

## Remarks

As a performance consideration, log output is flushed to disk only when the output buffer is full. By default, the buffer is 2144 bytes.

The **!logexts.logb p** extension displays the contents of the buffer in the debugger.

The **!logexts.logb f** extension flushes the buffer to the log files. Because the buffer memory is managed by the target application, the automatic writing of the buffer to disk will not occur if there is an access violation or some other nonrecoverable error in the target application. In such cases, you should use this command to manually flush the buffer to the disk. Otherwise, the most recently-logged APIs might not appear in the log files.

[Send comments about this topic to Microsoft](#)

# !logexts.logc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.logc** extension displays all API categories, displays all APIs in a specific category, or enables and disables the logging of APIs in one or more categories.

```
!logexts.logc e Categories
!logexts.logc d Categories
!logexts.logc p Category
!logexts.logc
```

## Parameters

### e

Enables logging of the specified categories.

### d

Disables logging of the specified categories.

### Categories

Specifies the categories to be enabled or disabled. If multiple categories are listed, separate them with spaces. An asterisk (\*) can be used to indicate all categories.

### p

Displays all APIs that belong to the specified category.

### Category

Specifies the category whose APIs will be displayed. Only one category can be specified with the **p** option.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

## Remarks

Without any options, **!logexts.logc** will display the current list of available categories and will indicate which ones are enabled and disabled.

If a category is disabled, the hooks for all APIs in that category will be removed so there is no longer any performance overhead. COM hooks are not removed, because they cannot be re-enabled at will.

Enabling only certain categories can be useful when you are only interested in a particular type of interaction that the program is having with Windows (for example, file operations). This reduces the log file size and also reduces the effect that Logger has on the execution speed of the process.

The following command will enable the logging of all categories:

```
0:000> !logexts.logc e *
```

The following command will disable the logging of category 7:

```
0:000> !logexts.logc d 7
```

The following command will enable the logging of categories 13 and 15:

```
0:000> !logexts.logc e 13 15
```

The following command will display all APIs belonging to category 3:

```
0:000> !logexts.logc p 3
```

[Send comments about this topic to Microsoft](#)

# !logexts.logd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.logd** extension disables logging.

```
!logexts.logd
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

## Remarks

This will cause all API hooks to be removed in an effort to allow the program to run freely. COM hooks are not removed, because they cannot be re-enabled at will.

[Send comments about this topic to Microsoft](#)

# !logexts.loge

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.loge** extension enables logging. If logging has not been initialized, it will be initialized and enabled.

```
!logexts.loge [OutputDirectory]
```

## Parameters

### *OutputDirectory*

Specifies the directory to use for output. If *OutputDirectory* is specified, it must exist -- the debugger will not create it. If a relative path is specified, it will be relative to the directory from which the debugger was started. If *OutputDirectory* is omitted, the path to the Desktop will be used. The debugger will create a LogExts subdirectory of *OutputDirectory*, and all Logger output will be placed in this subdirectory.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

## Remarks

If Logger has not yet been injected into the target application by the **!logexts.logi** extension, the **!logexts.loge** extension will inject Logger into the target and then enable logging.

If **!logexts.logi** has already been run, you cannot include *OutputDirectory*, because the output directory will have already been set.

[Send comments about this topic to Microsoft](#)

# !logexts.logi

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.logi** extension initializes logging by injecting Logger into the target application.

```
!logexts.logi [OutputDirectory]
```

## Parameters

### *OutputDirectory*

Specifies the directory to use for output. If *OutputDirectory* is specified, it must exist -- the debugger will not create it. If a relative path is specified, it will be relative to the directory from which the debugger was started. If *OutputDirectory* is omitted, the path to the Desktop will be used. The debugger will create a LogExts subdirectory of *OutputDirectory*, and all Logger output will be placed in this subdirectory.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

## Remarks

This command initializes logging, but does not actually enable it. Logging can be enabled with the [!logexts.loge](#) command.

[Send comments about this topic to Microsoft](#)

# !logexts.logm

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.logm** extension creates or displays a module inclusion list or a module exclusion list.

```
!logexts.logm i Modules
!logexts.logm x Modules
!logexts.logm
```

## Parameters

**i**

Causes Logger to use a module inclusion list. It will consist of the specified *Modules*.

**x**

Causes Logger to use a module exclusion list. It will consist of Logexts.dll, kernel32.dll, and the specified *Modules*.

*Modules*

Specifies the modules to be included or excluded. This list is not cumulative; each use of this command creates an entirely new list. If multiple modules are listed, separate them with spaces. An asterisk (\*) can be used to indicate all modules.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

## Remarks

With no parameters, the **!logexts.logm** extension displays the current inclusion list or exclusion list.

The extensions **!logexts.logm x \\*** and **!logexts.logm i** are equivalent: they result in a completely empty inclusion list.

The extensions **!logexts.logm i \\*** and **!logexts.logm x** are equivalent: they result in an exclusion list that contains only Logexts.dll and kernel32.dll. These two modules are always excluded, because Logger is not permitted to log itself.

Here are some examples:

```
0:001> !logm
Excluded modules:
 LOGEXTS.DLL [mandatory]
 KERNEL32.DLL [mandatory]
 USER32.DLL
 GDI32.DLL
 ADVAPI32.DLL

0:001> !logm x winmine.exe
Excluded modules:
 Logexts.dll [mandatory]
 kernel32.dll [mandatory]
 winmine.exe

0:001> !logm x user32.dll gdi32.dll
Excluded modules:
 Logexts.dll [mandatory]
 kernel32.dll [mandatory]
 user32.dll
 gdi32.dll

0:001> !logm i winmine.exe mymodule2.dll
Included modules:
 winmine.exe
 mymodule2.dll
```

[Send comments about this topic to Microsoft](#)

# !logexts.logo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!logexts.logo** extension sets or displays the Logger output options.

```
!logexts.logo {e|d} {d|t|v}
!logexts.logo
```

## Parameters

### e|d

Specifies whether to enable (e) or disable (d) the indicated output type.

### d|t|v

Specifies the output type. Three types of Logger output are possible: messages sent directly to the debugger (d), a text file (t), or a verbose .lgv file (v).

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Logexts.dll |
| <b>Windows XP and later</b> | Logexts.dll |

## Additional Information

For more information, see [Logger and LogViewer](#).

## Remarks

If **!logexts.logo** is used without any parameters, then the current logging status, the output directory, and the current settings for the debugger, text file, and verbose log are displayed:

```
0:000> !logo
Logging currently enabled.

Output directory: MyLogs\LogExts\

Output settings:
 Debugger Disabled
 Text file Enabled
 Verbose log Enabled
```

In the previous example, the output directory is a relative path, so it is located relative to the directory in which the debuggers were started.

To disable verbose logging, you would use the following command:

```
0:000> !logo d v
Debugger Disabled
Text file Enabled
Verbose log Disabled
```

Text file and .lgv files will be placed in the current output directory. To read an .lgv file, use LogViewer.

# NDIS Extensions (Ndiskd.dll)

5/31/2017 • 3 min to read • [Edit Online](#)

This section describes commands available in !ndiskd, a debugger extension that is useful for debugging NDIS (Network Device Interface Specification) drivers. These commands enable network driver developers to see a bigger picture of the Windows networking stack and how their drivers interact with it. With !ndiskd, you can see the state of all network adapters ([!ndiskd.netadapter](#)), a visual diagram of the computer's network stack ([!ndiskd.netreport](#)), a log of traffic on the network adapters ([!ndiskd.nbllog](#)), or a list of all pending OID requests ([!ndiskd.oid](#)).

The commands can be found in Ndiskd.dll. To load the symbols, enter **.reload /f ndis.sys** in the debugger command window. To confirm the symbols loaded successfully, use the **!lmi ndis** extension and look for the phrase "Symbols loaded successfully" toward the bottom. Your output should look similar to the following example:

```
3: kd> !lmi ndis
Loaded Module Info: [ndis]
 Module: ndis
 Base Address: ffffff80e2e150000
 Image Name: ndis.sys
 Machine Type: 34404 (X64)
 Time Stamp: 57f4c58d Wed Oct 5 02:19:09 2016
 Size: 128000
 CheckSum: 1213f7
 Characteristics: 22
 Debug Data Dirs: Type Size VA Pointer
 CODEVIEW 21, 7b1b8, 79fb8 RSDS - GUID: {06A2E58C-996D-4419-81A0-BB293BD63BCA}
 Age: 1, Pdb: ndis.pdb
 ?? 880, 7b1dc, 79fdc [Data not mapped]
 Image Type: MEMORY - Image read successfully from loaded memory.
 Symbol Type: PDB - Symbols loaded successfully from image header.
 c:\Debuggers\sym\ndis.pdb\06A2E58C996D441981A0BB293BD63BCA1\ndis.pdb
 Compiler: Linker - front end [0.0 bld 0] - back end [14.0 bld 23917]
 Load Report: private symbols & lines, source indexed
 c:\Debuggers\sym\ndis.pdb\06A2E58C996D441981A0BB293BD63BCA1\ndis.pdb
```

## !ndiskd Hyperlinks

Many of the extension commands in !ndiskd present you with hyperlinks in the results they display in the debugger window. The text for these hyperlinks has been left in the samples provided to illustrate the exact format of what you will see when you run the command on your debuggee machine. Some of the examples also refer explicitly to clicking on these links so you can understand typical usage flows, though the examples also provide the alternate command line forms of each command.

## Common Parameters

All !ndiskd commands support the following generic parameters.

*-verbose*

Shows additional details.

*-terse*

Suppresses some boilerplate output.

*-static*

Suppresses some interactive output.

*-dml 0|1*

Controls whether DML (debugger markup language) output is enabled.

*-unicode 0|1*

Controls whether Unicode character output is allowed.

*-indent N*

Uses *N* spaces per level of indent.

*-force*

Overrides some safety checks on remote data sanity.

*-tracedata*

Shows verbose trace messages to debug !ndiskd itself.

## Net Adapter, NDIS Driver, and General Commands

The following commands display information about the machine's network adapters, network drivers, and general commands associated with the network stack (such as rcvqueues, opens, filters, OIDs, and RW locks).

- **!ndiskd.netadapter**
- **!ndiskd.minidriver**
- **!ndiskd.rcvqueue**
- **!ndiskd.protocol**
- **!ndiskd.mopen**
- **!ndiskd.filter**
- **!ndiskd.filterdriver**
- **!ndiskd.oid**
- **!ndiskd.ndisrwlock**
- **!ndiskd.netreport**

## NET\_BUFFER\_LIST and NET\_BUFFER Commands

The following commands display information relating to **NET\_BUFFER\_LIST** and **NET\_BUFFER** structures.

- **!ndiskd.nbl**
- **!ndiskd.nb**
- **!ndiskd.nblpool**
- **!ndiskd.nbpool**
- **!ndiskd.pendingnbls**
- **!ndiskd.nbllog**

## NetAdapterCx Commands

The following commands display information relating to the Network Adapter WDF Class Extension (NetAdapterCx)[LINK TBD] and its associated structures, NET\_RING\_BUFFER [LINK TBD] and NET\_PACKET [LINK TBD].

- **!ndiskd.cxadapter**
- **!ndiskd.netqueue**
- **!ndiskd.netrb**

- [!ndiskd.netpacket](#)
- [!ndiskd.netpacketfragment](#)

## Network Interface Commands

The following commands display information relating to network interfaces.

- [!ndiskd.interfaces](#)
- [!ndiskd.ifprovider](#)

## NDIS\_PACKET Commands

The following commands display information about [NDIS\\_PACKET](#) structures. These extensions are for legacy NDIS 5.x drivers. The NDIS\_PACKET structure and its associated architecture have been deprecated.

- [!ndiskd.pkt](#)
- [!ndiskd.pktpools](#)
- [!ndiskd.findpacket](#)

## CoNDIS Commands

The following commands display information about [Connection-Oriented NDIS](#) connections.

- [!ndiskd.vc](#)
- [!ndiskd.af](#)

## NDIS Debugging Commands

The following commands display information relating to NDIS refcounts, event logs, stack traces, and debug traces.

- [!ndiskd.ndisref](#)
- [!ndiskd.ndisevent](#)
- [!ndiskd.ndisstack](#)
- [!ndiskd.dbglevel](#)
- [!ndiskd.dbgsystems](#)

## WDI Commands

The following commands display information about [WDI Miniport Drivers](#).

- [!ndiskd.wdiadapter](#)
- [!ndiskd.wdiminidriver](#)
- [!ndiskd.nwadapter](#)

## NDIS and !ndiskd Information Commands

The following commands display information about NDIS.sys and ndiskd.dll.

- [!ndiskd.ndis](#)
- [!ndiskd.ndiskdversion](#)

## Miscellaneous Commands

- [!ndiskd.ifstacktable](#)
- [!ndiskd.compartments](#)
- [!ndiskd.ndisslot](#)

## Related Topics

For more information about designing NDIS drivers for Windows Vista and later, see the [Network Driver Design Guide](#).

For more information about reference for NDIS drivers for Windows Vista and later, see [Windows Vista and Later Networking Reference](#).

# !ndiskd.help

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.help** command displays a list of available !ndiskd commands with a brief description of each one.

```
!ndiskd.help
```

## DLL

Ndiskd.dll

## Examples

The following example shows the list of help commands using **!ndiskd.help**.

```
3: kd> !ndiskd.help

NDIS KD EXTENSIONS

 help This help and lots more
 netadapter Show network adapters (this is a good starting place)
 protocol Show protocol drivers
 mopen Show open bindings between netadapter and protocol
 filter Show light-weight filters
 nbl Show information about an NET_BUFFER_LIST
 oid Show pending OID Requests
 ndis Show NDIS.sys build info
 netreport Draw a box diagram of your network stack

 Show more extensions
 View examples & tutorials online
```

By using **!ndiskd.help -all**, you'll get a more detailed list, as shown in the following example.

### Note

Some alternate commands are listed at the bottom of this example. These commands are available for NDIS driver developers who have used them before but we recommend using the primary commands instead.

```
3: kd> !ndiskd.help -all

NDIS KD EXTENSIONS

Primary commands:
help This help and lots more
netadapter Show network adapters (this is a good starting place)
 minidriver Show network adapter drivers
 rcvqueue Show a receive queue (c.f. VMQ)
protocol Show protocol drivers
mopen Show open bindings between netadapter and protocol
filter Show light-weight filters
 filterdriver Show filter drivers (not to be confused with filters)
nbl Show information about an NET_BUFFER_LIST
nb Show information about an NET_BUFFER
nblpool Show information about an NET_BUFFER_LIST pool
nbpool Show information about an NET_BUFFER pool
pendingnbls Show all NET_BUFFER_LISTs that are in transit
nbllog Show a log of all NET_BUFFER_LIST activity
oid Show pending OID Requests
interfaces Show interfaces (à la NDISIF)
 ifprovider Show registered NDIS interface providers
 ifstacktable Show the ifStackTable
 networks Show networks (probably not what you think)
 compartments Show compartments
pkt Show a NDIS_PACKET structure
 pktpools Show all allocated packet pools
 findpacket Find a packet in memory
vc Show a CoNDIS virtual connection
af Show a CoNDIS address family
ndisref Show a debug log of refcounts
ndisevent Show a debug log of events
ndisstack Show a debug stack trace
wdiadapter Shows one or more WDIWiFi!CAdapter structures
wdiminidriver Shows one or more CMiniportDriver structures
nwadapter Shows one or more nwifi!ADAPT structures
ndisrwlock Show an NDIS_RW_LOCK_EX lock
ndisslot Show an NDIS per-processor slot
ndis Show NDIS.sys build info
 dbglevel Change the debugging level [checked NDIS.sys only]
 dbgsystems Toggle subsystems being debugged [checked NDIS.sys only]
 ndiskdversion Show info about NDISKD itself
netreport Draw a box diagram of your network stack

Alternate commands:
miniport Same as !ndiskd.netadapter
gminiports Same as !ndiskd.netadapter
miniports "Classic" version of !ndiskd.netadapter
filterdb Same as !ndiskd.netadapter -filterdb
offload Same as !ndiskd.netadapter -offloads
ports Same as !ndiskd.netadapter -ports
rcvqueues Same as !ndiskd.netadapter -rcvqueues
filters Same as !ndiskd.filter
opens Same as !ndiskd.mopen
protocols Same as !ndiskd.protocol
nblpools Same as !ndiskd.nblpool
nbpools Same as !ndiskd.nbpool
```

## **NDIS extensions (Ndiskd.dll)**

[Send comments about this topic to Microsoft](#)

# !ndiskd.netadapter

5/31/2017 • 4 min to read • [Edit Online](#)

The **!ndiskd.netadapter** extension displays information about NDIS miniports, or network adapters, that are active on the system. If you run this command with no parameters, !ndiskd will display a list of all network adapters.

```
!ndiskd.netadapter [-handle <x>] [-basic] [-diag] [-state] [-bindings]
[-ports] [-offloads] [-filterdb] [-timers] [-rst]
[-pm] [-ss] [-aoac] [-wol] [-protocoloffloads]
[-rss] [-hw] [-device] [-wmi] [-customwmi]
[-ndiswmi] [-ref] [-log] [-grovel] [-findname <any>]
[-rcvfilter] [-nicswitch] [-rcvqueues] [-nicswitches] [-iov]
[-vfs] [-vports] [-iftrace] [-ip]
```

## Parameters

*-handle*

Handle of an NDIS miniport.

*-basic*

Displays summary information about the miniport.

*-diag*

Displays auto-diagnostic alerts (if any).

*-state*

Displays the miniport's current state.

*-bindings*

Displays miniport bindings.

*-ports*

Shows a list of NDIS ports.

*-offloads*

Shows task offload state and capabilities.

*-filterdb*

Shows the current packet filter.

*-timers*

Shows timer objects allocated by the miniport.

*-rst*

Shows Receive-Side Throttling state.

*-pm*

Shows power management state and capabilities.

*-ss*

Shows Selective Suspend state.

*-aoac*

Shows AOAC (Connected Standby) state.

*-wol*

Shows Wake-on-LAN (WoL) configuration.

*-protocoloffloads*

Shows active power management protocol offloads.

*-rss*

Shows Receive Side Scaling parameters.

*-hw*

Displays hardware resources.

*-device*

Shows information about the underlying NT device object.

*-wmi*

Shows WMI GUIDs registered to the adapter.

*-customwmi*

Shows custom WMI GUIDs registered by the miniport.

*-ndiswmi*

Shows NDIS-provided WMI GUIDs.

*-ref*

Shows a breakdown of references on the miniport.

*-log*

Displays a PnP and Power event log.

*-grovel*

Forces a search for miniport blocks in memory.

*-findname*

Filters miniports by name prefix.

*-rcvfilter*

Shows receive filtering capabilities.

*-nicswitch*

Shows NIC switch capabilities.

*-rcvqueues*

Shows receive queues.

*-nicswitches*

Shows NIC switches.

*-iov*

Shows SR-IOV (Single Root I/O Virtualization) capabilities.

*-vfs*

Shows SR-IOV VFs (Virtual Filters).

*-vports*

Shows Vports (Virtual ports).

*-ifrtrace*

Shows the in-flight recorder's trace.

*-ip*

Shows IP addresses on the network's interface.

## DLL

Ndiskd.dll

## Examples

By running **!ndiskd.netadapter** with no parameters, you can get a list of all network adapters on the system along with their associated miniport drivers. In this example output, look for the Microsoft Kernel Debug Network Adapter, whose handle is fffffdf80140c71a0. For more information about what the Kernel Debug Network Adapter is, see [Kernel debugging over the network](#) on the NDIS blog.

```
3: kd> !ndiskd.netadapter
 Driver NetAdapter Name
 fffffdf8015a98380 fffffdf8015aa11a0 Microsoft ISATAP Adapter #2
 fffffdf801418d650 fffffdf80140c71a0 Microsoft Kernel Debug Network Adapter
```

By clicking on the handle for the miniport driver or entering the **!ndiskd.netadapter -handle**, you can now see all of NDIS's state on that device. This can be very helpful as a starting place for troubleshooting a network driver or for figuring out where an issue is in the network stack. For example, you can see the Datapath state for the driver and see whether it is connected or not.

At the bottom of the report for this net adapter, there are many other links you can click on to explore further information, such as any pending OIDs and the state of task offloads. These links correspond to many of the parameters for **!ndiskd.netadapter**.

```
3: kd> !ndiskd.netadapter fffffdf80140c71a0

| WFP Native MAC Layer LightWeight Filter-0000 |                   |                                          |                   |
|                                              | fffffdf80139fc70  | fffffdf8014950c70                        | fffffdf8014950880 |

#### MORE INFORMATION

|                    |                         |
|--------------------|-------------------------|
| Driver handlers    | Task offloads           |
| Power management   | PM protocol offloads    |
| Pending OIDs       | Timers                  |
| Pending NBLs       | Receive side throttling |
| Wake-on-LAN (WoL)  | Packet filter           |
| Receive queues     | Receive filtering       |
| RSS                | NIC switch              |
| Hardware resources | Selective suspend       |
| NDIS ports         | WMI guides              |
| Diagnostic log     |                         |

As example of using **!ndiskd.netadapter** as a starting place for further debugging, click on the "Driver handlers" link at the bottom of the report to see a list of all registered driver callback handlers for this net adapter's miniport driver. In the following example, clicking the link causes !ndiskd to run the **!ndiskd.minidriver** extension with the handle of this net adapter's miniport driver. The miniport driver is the kdnic 4.2 and its handle is fffffdf801418d650.

```
3: kd> !ndiskd.minidriver fffffdf801418d650 -handlers
```

#### HANDLERS

| NDIS Handler                  | Function pointer | Symbol (if available) |
|-------------------------------|------------------|-----------------------|
| InitializeHandlerEx           | fffff80f1fd78230 | bp                    |
| SetOptionsHandler             | fffff80f1fd72800 | bp                    |
| HaltHandlerEx                 | fffff80f1fd78040 | bp                    |
| ShutdownHandlerEx             | fffff80f1fd722c0 | bp                    |
|                               |                  |                       |
| CheckForHangHandlerEx         | fffff80f1fd72810 | bp                    |

|                               |                  |                       |
| PauseHandler                  | fffff80f1fd78000 | bp                    |
| RestartHandler                | fffff80f1fd78940 | bp                    |
|                               |                  |                       |
| OidRequestHandler             | fffff80f1fd71c90 | bp                    |
| CancelOidRequestHandler       | fffff80f1fd722c0 | bp                    |
| DirectOidRequestHandler       | [None]           |                       |
| CancelDirectOidRequestHandler | [None]           |                       |
| DevicePnPEventNotifyHandler   | fffff80f1fd789a0 | bp                    |
|                               |                  |                       |
| SendNetBufferListsHandler     | fffff80f1fd71870 | bp                    |
| ReturnNetBufferListsHandler   | fffff80f1fd71b50 | bp                    |
| CancelSendHandler             | fffff80f1fd722c0 | bp                    |

You can now click the "bp" link to the right of each handler to set a breakpoint on that handler to debug a particular problem. For example, if there is a hang in the datapath, you can investigate the driver's SendNetBufferListsHandler or ReturnNetBufferListsHandler.

# !ndiskd.minidriver

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.minidriver** command displays information about an NDIS miniport driver. If you run this extension with no parameters, !ndiskd will display a list of NDIS miniport drivers that are active on the system.

```
!ndiskd.minidriver [-handle <x>] [-basic] [-miniports] [-devices] [-handlers]
```

## Parameters

### *-handle*

Handle of an NDIS miniport driver.

### *-basic*

Displays basic information about the miniport driver.

### *-miniports*

Displays the miniports associated with this miniport driver.

### *-devices*

Displays devices associated with this miniport driver.

### *-handlers*

Displays this driver's miniport handlers.

## DLL

Ndiskd.dll

## Examples

Enter the **!ndiskd.minidriver** command with no parameters to get a list of all NDIS miniport drivers active on the system. In the following example, look for the kdnic adapter's handle, fffffd20d12dec020

```
1: kd> !ndiskd.minidriver -basic
fffffd20d173deae0 - tunnel
fffffd20d12dec020 - kdnic
```

Using the handle for the kdnic adapter, you can now click on the handle or enter the **!ndiskd.minidriver -handle** command to see detailed information for the tunnel miniport driver, as well as a list of miniports associated with it.

```
1: kd> !ndiskd.minidriver fffffd20d12dec020

MINIPORT DRIVER

 kdnic

 Ndis handle fffffd20d12dec020 [type it]
 Driver context fffff80d2fa15100
 DRIVER_OBJECT fffffd20d12dee540
 Driver image kdnic.sys

**[!ndiskd.help](#)**

[Send comments about this topic to Microsoft](#)

# !ndiskd.rcvqueue

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.rcvqueue** command displays information about a receive queue.

```
!ndiskd.rcvqueue [-handle <x>] [-filters] [-mem] [-verbose] [-rcvqueueverbosity <x>]
```

## Parameters

### *-handle*

Required. Handle of a receive queue.

### *-filters*

Shows filters on the queue.

### *-mem*

Shows shared memory allocations.

### *-verbose*

Shows additional details.

### *-rcvqueueverbosity*

Level of detail to display.

## DLL

Ndiskd.dll

## Examples

To obtain the receive queue handle, first enter the **!ndiskd.netadapter** command with no parameters to see the list of net adapters, their drivers, and their handles. In the following example, look for the Microsoft ISATAP Adapter #2's NetAdapter handle, ffff8083e02ce1a0.

```
3: kd> !ndiskd.netadapter
 Driver NetAdapter Name
 ffff8083e2668970 ffff8083e02ce1a0 Microsoft ISATAP Adapter #2
 ffff8083e210fae0 ffff8083e0f501a0 Microsoft Kernel Debug Network Adapter
```

Next, with the net adapter's handle, use the **!ndiskd.netadapter -handle -rcvqueues** command to obtain a list of receive queues for this net adapter along with their handles. In this example, there is only one receive queue (the default one) with a handle of ffff8083e3a3d3a0.

```
3: kd> !ndiskd.netadapter fffff8083e02ce1a0 -rcvqueues
```

RECEIVE QUEUES

| QueueId     | Queue Handle      | Processor Affinity              |
|-------------|-------------------|---------------------------------|
| 0 [Default] | fffff8083e3a3d3a0 | 0:0000000000000000 (group:mask) |
|             | Queue Name:       | [Zero-length string]            |
|             | VM Name:          | [Zero-length string]            |

Now you can use the queue handle to examine the receive queue details with the **!ndiskd.rcvqueue** command.

```
3: kd> !ndiskd.rcvqueue fffff8083e3a3d3a0
```

RECEIVE QUEUE

|                           |                                                 |
|---------------------------|-------------------------------------------------|
|                           | [Zero-length string]                            |
| VM name                   | [Zero-length string]                            |
| QueueId                   | 0                                               |
| Ndis handle               | fffff8083e3a3d3a0                               |
| Miniport                  | fffff8083e02ce1a0 - Microsoft ISATAP Adapter #2 |

# !ndiskd.protocol

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.protocol** command displays information about an NDIS protocol driver. If you run this extension with no parameters, !ndiskd will display a list of NDIS protocol drivers that are active on the system.

```
!ndiskd.protocol [-handle <x>] [-findname <any>]
```

## Parameters

*-handle*

Handle of an NDIS protocol.

*-findname*

Filters protocols by name prefix.

## DLL

Ndiskd.dll

## Examples

Enter the **!ndiskd.protocol** command to see a list of all NDIS protocols, their handles, and open bindings to miniports (if any). In the following example, look for the TCPIP6TUNNEL protocol's handle, fffff8083e1a95c00.

```
3: kd> !ndiskd.protocol
fffff8083e0114730 - NDISUIO
fffff8083e55f3010 - Microsoft Kernel Debug Network Adapter

fffff8083e3e90c10 - MSLLDP
fffff8083e3926010 - Microsoft Kernel Debug Network Adapter

# !ndiskd.mopen

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.mopen** extension displays information about bindings between miniports and protocols. If you run this extension with no parameters, !ndiskd will display a list of all open bindings between NDIS miniport drivers and protocol drivers.

```
!ndiskd.mopen [-handle <xx>] [-ref]
```

## Parameters

*-handle*

Handle of an NDIS open binding.

*-ref*

Shows refcounts of open bindings.

## DLL

Ndiskd.dll

## Examples

Enter the !ndiskd.mopen command to get a list of all open bindings. In this example, look for the binding between the Microsoft ISATAP Adapter #2 miniport and the TCPIP6TUNNEL protocol. Its handle is ffff8083e56b8110.

```
3: kd> !ndiskd.mopen
Open ffff8083e56b8110
 Miniport: ffff8083e02ce1a0 - Microsoft ISATAP Adapter #2
 Protocol: ffff8083e1a95c00 - TCPIP6TUNNEL

Open ffff8083e11902c0
 Miniport: ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter
 Protocol: ffff8083e3e8f6b0 - RSPNDR

Open ffff8083e55f3010
 Miniport: ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter
 Protocol: ffff8083e0114730 - NDISUIO

Open ffff8083e15537d0
 Miniport: ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter
 Protocol: ffff8083e3e90800 - LLTDIO

Open ffff8083e3926010
 Miniport: ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter
 Protocol: ffff8083e3e90c10 - MSLLDP

Open ffff8083e0c565a0
 Miniport: ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter

# !ndiskd.filter

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.filter** extension displays information about an NDIS light-weight filter (LWF). If you run this extension with no parameters, !ndiskd will display a list of all LWFs.

```
!ndiskd.filter [-handle <x>] [-findname <any>] [-handlers]
```

## Parameters

*-handle*

Handle of an NDIS light-weight filter.

*-findname*

Filters LWFs by name prefix.

*-handlers*

Displays this LWF's filter handlers.

## DLL

Ndiskd.dll

## Examples

Enter the **!ndiskd.filter** command with no parameters to get a list of all filters. In this example, look for the ffff8083e14e8460 handle. Note that this handle is for the filter itself and is nested under its associated filter *driver*, the QoS Packet Scheduler.

```
3: kd> !ndiskd.filter
ffff8083e1a7fd90 - QoS Packet Scheduler
 Filter ffff8083e14e8460, Miniport ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter
 ffff8083e1a96b80 - Virtual WiFi Filter Driver
 ffff8083e19c4b70 - WFP vSwitch Layers LightWeight Filter
 ffff8083e19a6ad0 - WFP Native MAC Layer LightWeight Filter
 Filter ffff8083e43df8f0, Miniport ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter
 ffff8083e19a6d70 - WFP 802.3 MAC Layer LightWeight Filter
 Filter ffff8083e0d89c70, Miniport ffff8083e0f501a0 - Microsoft Kernel Debug Network Adapter
```

By using this filter handle we can now see more detailed information about it, such as its State, Higher filter handle, and Lower filter handle.

```
3: kd> !ndiskd.filter fffff8083e14e8460
```

#### FILTER

**[!ndiskd.help](#)**

[Send comments about this topic to Microsoft](#)

# !ndiskd.filterdriver

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.filterdriver** extension displays information about an NDIS filter driver. If you run this extension with no parameters, !ndiskd will display a list of all filter drivers.

```
!ndiskd.filterdriver [-handle <x>] [-filters] [-handlers]
```

## Parameters

### *-handle*

Handle of an NDIS filter driver.

### *-filters*

Displays instances of this driver's filters.

### *-handlers*

Displays this driver's filter handlers.

## DLL

Ndiskd.dll

## Examples

Run **!ndiskd.filterdriver** with no parameters to see a list of all filter drivers on the system. In the following example, look for the Virtual WiFi Filter Driver, whose handle is fffffbc064cc83be0.

```
0: kd> !ndiskd.filterdriver
fffffb064cccd4900 - QoS Packet Scheduler
fffffb064cc83be0 - Virtual WiFi Filter Driver
fffffb064cb91a10 - WFP vSwitch Layers LightWeight Filter
fffffb064cb8fd70 - WFP Native MAC Layer LightWeight Filter
fffffb064cb59b00 - WFP 802.3 MAC Layer LightWeight Filter
```

By clicking the filter driver handle from the previous example or by using it to enter the **!ndiskd.filterdriver - handle** command in the command window, you can get see more detailed information about that filter driver. In this case, for example, there are no filter modules for this filter driver.

```
0: kd> !ndiskd.filterdriver fffffbc064cc83be0
```

#### FILTER DRIVER

```
Virtual WiFi Filter Driver

# !ndiskd.nbl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.nbl** extension displays information about a **NET\_BUFFER\_LIST** (NBL) structure.

```
!ndiskd.nbl [-handle <x>] [-basic] [-chain] [-info] [-data]
[-netmon] [-capfile <str>] [-launch] [-overwrite] [-log]
[-stacks] [-NblCurrentOwner]
```

## Parameters

*-handle*

Required. Address of a **NET\_BUFFER\_LIST** structure.

*-basic*

Displays basic information about an NBL.

*-chain*

Displays all the NBLs and **NET\_BUFFER**s in an NBL chain.

*-info*

Displays all the out-of-band information that is associated with an NBL.

*-data*

Displays the actual data payload of an NBL.

*-netmon*

Views the NBL chain in Microsoft Network Monitor.

*-capfile*

Specifies the path to which a netmon capture is saved.

*-launch*

Automatically launches netmon.exe after saving the capture file.

*-overwrite*

Allows overwriting the capture file if it already exists.

*-log*

Shows NBL log if NBL history logging is enabled.

*-stacks*

Includes callstacks with NBL log (use with -log).

*-NblCurrentOwner*

Shows the current owner of the NBL.

## DLL

Ndiskd.dll

## Examples

In the following example, NBL tracking has been enabled to extract a handle for an NBL from the NBL log. For more

information about NBL tracking and the NBL log, see [!ndiskd.nbllog](#).

At the time of log collection, the NBL in this example was returned by the TCPIP6 protocol to the WFP Native Mac Layer LightWeight Filter.

```
2: kd> !ndiskd.nbl fffffdf80149524a0
 NBL fffffdf80149524a0 Next NBL NULL
 First NB fffffdf8014952610 Source fffffdf80140c71a0 - Microsoft Kernel Debug
Network Adapter
 Flags INDICATED, RETURNED, NBL_ALLOCATED, PROTOCOL_020_0,
 PROTOCOL_200_0

 Walk the NBL chain Dump data payload
 Show out-of-band information
 Review NBL history
```

By clicking on the "Dump data payload" link from the previous example or by entering the [!ndiskd.nbl -handle -data](#) command, you can see the data payload of this NBL. In the following example, the NBL contains only one **NET\_BUFFER** structure. To further explore the contents of that **NET\_BUFFER** structure, run the [!ndiskd.nb -handle](#) command with its handle.

```
2: kd> !ndiskd.nbl fffffdf80149524a0 -data
 NET_BUFFER fffffdf8014952610
```

# !ndiskd.nb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.nb** extension displays information about a **NET\_BUFFER** (NB) structure.

```
!ndiskd.nb [-handle <x>] [-verbosity <x>] [-basic] [-chain] [-data]
```

## Parameters

*-handle*

Required. Address of a **NET\_BUFFER** structure.

*-verbosity*

Level of detail to display.

*-basic*

Displays basic information about an NB.

*-chain*

Displays all the MDLs associated with an NB.

*-data*

Dumps the actual data payload of an NB.

## DLL

Ndiskd.dll

## Examples

The **NET\_BUFFER** in the following examples was obtained from the **NET\_BUFFER\_LIST** in the Examples section of the **!ndiskd.nbl** topic. The NB's handle is fffffdf8014952610.

```
2: kd> !ndiskd.nbl fffffdf80149524a0 -data
NET_BUFFER fffffdf8014952610
```

You can click the **NET\_BUFFER**'s handle or run the **!ndiskd.nb -handle** command to see its details.

```
2: kd> !ndiskd.nb fffffdf8014952610
NB fffffdf8014952610 Next NB 0
Length 0 Source pool fffffdf80147e4a40
First MDL fffffdf8014a37930 DataOffset 0
Current MDL [First MDL] Current MDL offset 0

View associated NBL
```

Use the **!ndiskd.nb -chain** command to see this **NET\_BUFFER**'s MDL chain in addition to its basic details. In the following example, there is only one MDL. Its handle is fffffdf8014a37930.

```
2: kd> !ndiskd.nb fffffdf8014952610 -chain
 NB fffffdf8014952610 Next NB 0
 Length 0 Source pool fffffdf80147e4a40
 First MDL fffffdf8014a37930 DataOffset 0
 Current MDL [First MDL] Current MDL offset 0
 MDL [current] fffffdf8014a37930 MDL Flags c
 MappedSystemVa fffffdf8014bf0024 ByteCount 0n1514
 Process [System process] ByteOffset 0n36
```

# !ndiskd.nblpool

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.nblpool** extension displays information about a **NET\_BUFFER\_LIST** (NBL) pool. If you run this extension with no parameters, !ndiskd will display a list of all allocated NBL pools in the system.

```
!ndiskd.nblpool [-handle <x>] [-basic] [-allocations] [-find <str>] [-findnb <str>]
[-findctx <str>] [-findctxtype <str>] [-findva <x>] [-findpa <x>]
```

## Parameters

### *-handle*

Handle of an NBL pool.

### *-basic*

Displays basic information about the NBL pool.

### *-allocations*

Displays all allocated NBLs.

### *-find*

Filter the list of allocated NBLs using a debugger expression.

### *-findnb*

Filter the list of allocated NBLs by linked **NET\_BUFFER**s (NBs).

### *-findctx*

Filter the list of allocated NBLs by context area.

### *-findctxtype*

Override the datatype of the context area.

### *-findva*

Find NBLs that contain an NB that straddles the given virtual address.

### *-findpa*

Find NBLs that contain an NB that straddles the given physical address.

## DLL

Ndiskd.dll

## Examples

Enter the **!ndiskd.nblpool** command with no parameters to see a list of all allocated NBL pools. In this example, look for the NBL pool allocated by the kernel debugger network interface card (kdnic) with the KDNr Tag. Its handle is fffffdf80147e4a40.

```
2: kd> !ndiskd.nblpool

# !ndiskd.nbpool

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.nbpool** extension displays information about a **NET\_BUFFER** (NB) pool. If you run this extension with no parameters, !ndiskd will display a list of all allocated NB pools in the system.

```
!ndiskd.nbpool [-handle <x>] [-allocations] [-find <str>] [-findva <x>] [-findpa <x>]
```

## Parameters

**-handle**

Handle of an NB pool.

**-allocations**

Displays all allocated NBs.

**-find**

Filter the list of allocated NBs using a debugger expression.

**-findva**

Find NBs that straddle the given virtual address.

**-findpa**

Find NBs that straddle the given physical address.

## DLL

Ndiskd.dll

## Examples

Enter the **!ndiskd.nbpool** command with no parameters to see a list of all allocated NB pools. In this example, look for the NB pool allocated by the Netio service with the Nnbf Tag. Its handle is fffffdf801308ca40.

```
2: kd> !ndiskd.nbpool
NB Pool Tag Allocated by

[Send comments about this topic to Microsoft](#)

# !ndiskd.pendingnbls

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.pendingnbls** extension displays pending NBLs ([NET\\_BUFFER\\_LISTs](#)) that are in transit.

```
!ndiskd.pendingnbls [-handle <x>] [-fullstack] [-verbosity <x>]
```

## Parameters

*-handle*

Handle of an NDIS miniport, filter, or open.

*-fullstack*

Shows pending NBLs from the entire stack associated with the handle.

*-verbosity*

Level of detail to display.

## DLL

Ndiskd.dll

## Examples

**!ndiskd.pendingnbls** can be passed the handle of an NDIS miniport, filter, or open. The following series of examples use a miniport handle. To see a list of all miniports and their associated minidrivers, run the **!ndiskd.netadapter** extension with no parameters. In the following example output, look for the Microsoft Kernel Debug Network Adapter, whose handle is fffffe00bc3f701a0. Its minidriver's handle is fffffe00bc51b9ae0.

```
0: kd> !ndiskd.netadapter
 Driver NetAdapter Name
fffffe00bc6e12ae0 fffffe00bc6e4e1a0 Microsoft ISATAP Adapter #2
fffffe00bc51b9ae0 fffffe00bc3f701a0 Microsoft Kernel Debug Network Adapter
```

To see the pending NBLs for a miniport, set a breakpoint on its minidriver's `SendNetBufferListsHandler`. Use the minidriver's handle to run the **!ndiskd.minidriver -handle -handlers** command to see a list of its handlers, then click the "bp" link to the right of the `SendNetBufferListsHandler`. You can alternatively enter the **bp -handle** command in the command line.

```
0: kd> !ndiskd.minidriver fffffe00bc51b9ae0 -handlers
```

#### HANDLERS

| NDIS Handler                  | Function pointer | Symbol (if available) |
|-------------------------------|------------------|-----------------------|
| InitializeHandlerEx           | fffff80ae9618230 | bp                    |
| SetOptionsHandler             | fffff80ae9612800 | bp                    |
| HaltHandlerEx                 | fffff80ae9618040 | bp                    |
| ShutdownHandlerEx             | fffff80ae96122c0 | bp                    |
| CheckForHangHandlerEx         | fffff80ae9612810 | bp                    |
| ResetHandlerEx                | fffff80ae9612f70 | bp                    |
| PauseHandler                  | fffff80ae9618000 | bp                    |
| RestartHandler                | fffff80ae9618940 | bp                    |
| OidRequestHandler             | fffff80ae9611c90 | bp                    |
| CancelOidRequestHandler       | fffff80ae96122c0 | bp                    |
| DirectOidRequestHandler       | [None]           |                       |
| CancelDirectOidRequestHandler | [None]           |                       |
| DevicePnPEventNotifyHandler   | fffff80ae96189a0 | bp                    |
| SendNetBufferListsHandler     | fffff80ae9611870 | bp                    |
| ReturnNetBufferListsHandler   | fffff80ae9611b50 | bp                    |
| CancelSendHandler             | fffff80ae96122c0 | bp                    |

After setting the breakpoint on the SendNetBufferListsHandler, enter the **g** command to let the debuggee target machine run and hit the breakpoint.

```
0: kd> bp fffff80ae9611870
0: kd> g
Breakpoint 0 hit
fffff80a`e9611870 4053 push rbx
```

Now, after hitting the minidriver's SendNetBufferListsHandler breakpoint, you can see any pending NBLs for the miniport by entering the **!ndiskd.pendingnbls -handle** command with the miniport's handle.

#### Note

The debuggee target machine in this example was loading a web page when it hit the breakpoint, so traffic was flowing through the miniport's datapath. Therefore, it had a pending NBL to send. Even after setting a breakpoint on one or more of the NBL handlers for the minidriver, you may not see any pending NBLs if there were no activity in the datapath.

```
0: kd> !ndiskd.pendingnbls fffffe00bc3f701a0

PHASE 1/3: Found 20 NBL pool(s).
PHASE 2/3: Found 342 freed NBL(s).

Pending Nbl Currently held by
fffffe00bc5545c60 fffffe00bc3f701a0 - Microsoft Kernel Debug Network Adapter [NetAdapter]

# !ndiskd.nbllog

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.nbllog** extension displays the log of all NBL ([NET\\_BUFFER\\_LIST](#)) activity on the system.

```
!ndiskd.nbllog [-stacks]
```

## Parameters

*-stacks*

Include callstacks.

### DLL

Ndiskd.dll

## Remarks

### Important

**!ndiskd.nbllog** requires NBL tracking to be enabled on the debuggee target machine. NBL tracking is not enabled by default in all configurations of Windows. If NBL tracking is not enabled, !ndiskd will give you instructions on how to enable it, as shown in the following snippet.

```
0: kd> !ndiskd.nbllog
This command requires NBL tracking to be enabled on the debuggee target
machine. (By default, client operating systems have level 1, and servers
have level 0). To enable, set this REG_DWORD value to a nonzero value on
the target machine and reboot the target machine:

HKLM\SYSTEM\CurrentControlSet\Services\NDIS\Parameters ! TrackNblOwner
Possible Values (features are cumulative)
* 0: Disable all tracking.
* 1: Track the most recent owner of each NBL (enables !ndiskd.pendingnbls)
* 2: Scan for leaks at runtime (use with StuckNblReaction)
* 3: Keep a full history of all activity (enables !ndiskd.nbl -log)
* 4: Take stack capture snapshots (enables !ndiskd.nbl -log -stacks)
This command requires level 3 or higher.
```

The NBL log shows network traffic on the system. [!ndiskd.netreport](#) parses the NBL tracking log to display this network traffic visually. Therefore, if NBL tracking is not enabled, [!ndiskd.netreport](#) will not be able to show you this information.

## Examples

After you have enabled NBL tracking on the target debuggee machine, enter the **!ndiskd.nbllog** command to see the log of all NBL traffic on the system. As shown in the example below, running **!ndiskd.nbllog** with no parameters will limit output to 200 events, which can be bypassed by rerunning the command with the *-force* option. The middle of the output in this example has been excised for brevity.

```

# !ndiskd.cxadapter

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.cxadapter** extension displays information about a NETADAPTER object.

For more information about the Network Adapter WDF Class Extension (NetAdapterCx), see [Network Adapter WDF Class Extension \(Cx\)](#).

```
!ndiskd.cxadapter [-handle <x>] [-basic] [-power] [-datapath]
```

## Parameters

*-handle*

Required. Handle of a NETADAPTER.

*-basic*

Displays basic information.

*-power*

Displays information about the NETPOWERSETTINGS object of the NETADAPTER.

*-datapath*

Displays information about the datapath queues.

## DLL

Ndiskd.dll

## Examples

To obtain a handle for a NETADAPTER object, first run the **!ndiskd.netadapter** command to see a list of all NIC drivers and NetAdapters on the system. In the following example, look for the handle for the NetAdapter named Realtek PCIe GBE Family Controller NetAdapter Sample Driver #2. Its handle is fffffd1022d048030.

```
0: kd> !ndiskd.netadapter
 Driver NetAdapter Name
 fffffd1022e8ecae0 fffffd1022d048030 Realtek PCIe GBE Family Controller NetAdapter Sample Driver #2
 fffffd1022ed908e0 fffffd1022e8611a0 Microsoft Kernel Debug Network Adapter
```

By clicking on this NetAdapter's handle or by entering the **!ndiskd.netadapter -handle** command with its handle on the command line, you can see details for this NetAdapter, including its NETADAPTER object. The Realtek PCIe GBE Family Controller NetAdapter Sample Driver #2's NETADAPTER handle is 00002efdd0e5f988.

```
0: kd> !ndiskd.netadapter fffffd1022d048030

Because the NETADAPTER object is a WDF object, clicking its handle will cause the debugger to run the **!wdfkd.wdfhandle** command which will give you more information about it from a WDF perspective. To see more detailed information about the NETADAPTER from a networking perspective, click the "More Information" link to the right of the NETADAPTER's handle to run the **!ndiskd.cxadAPTER** command with its handle.

```
0: kd> !ndiskd.cxadAPTER fffffd1022f1a0720

# !ndiskd.netqueue

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.netqueue** extension displays information about a NETTXQUEUE or NETRXQUEUE object.

For more information about the Network Adapter WDF Class Extension (NetAdapterCx), see [Network Adapter WDF Class Extension \(Cx\)](#).

```
!ndiskd.netqueue [-handle <x>] [-basic]
```

## Parameters

*-handle*

Required. Handle of a NETTXQUEUE or NETRXQUEUE.

*-basic*

Displays basic information.

## DLL

Ndiskd.dll

## Examples

**Note** See [Summary of Objects](#) to see a diagram explaining the relationship of the NETTXQUEUE and NETRXQUEUE objects with other objects in the NetAdapterCx.

To obtain a handle for a NETTXQUEUE or NETRXQUEUE, follow these steps:

1. Run the **!ndiskd.netadapter** extension.
2. Click on the handle for a NetAdapter that has a NetAdapterCx driver installed.
3. Click the "More Information" link to the right of the NetAdapter's NETADAPTER object to run the **!ndiskd.cxadapter** extension.
4. Enter the **!ndiskd.cxadapter** command with the *-datapath* parameter to see that NETADAPTER's datapath queues.

For details on this procedure, see the examples on the **!ndiskd.cxadapter** topic. In the following example, look for the handle for this NETADAPTER's NETTXQUEUE, fffffd1022f512700.

```
0: kd> !ndiskd.cxadapter fffffd1022f1a0720 -basic -datapath
```

#### NETADAPTER

# !ndiskd.netrb

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.netrb** extension displays information about a [NET\\_RING\\_BUFFER](#) structure.

For more information about the Network Adapter WDF Class Extension (NetAdapterCx), see [Network Adapter WDF Class Extension \(Cx\)](#).

```
!ndiskd.netrb [-handle <xx>] [-basic] [-dump] [-elementtype <str>]
```

## Parameters

*-handle*

Required. Address of a NET\_RING\_BUFFER.

*-basic*

Displays basic information.

*-dump*

Displays information about each element in the NET\_RING\_BUFFER.

*-elementtype*

A string for the data type to use when referring to a ring buffer element.

## DLL

Ndiskd.dll

## Examples

**Note** See [Summary of Objects](#) to see a diagram explaining the relationship of the NET\_RING\_BUFFER object with other objects in the NetAdapterCx.

To obtain a handle for a NET\_RING\_BUFFER, follow these steps:

1. Run the [!ndiskd.netadapter](#) extension.
2. Click on the handle for a NetAdapter that has a NetAdapterCx driver installed.
3. Click the "More Information" link to the right of the NetAdapter's NETADAPTER object to run the [!ndiskd.cxadapter](#) extension.
4. Enter the [!ndiskd.cxadapter](#) command with the *-datapath* parameter to see that NETADAPTER's datapath queues.
5. Click on the handle for one of the datapath queues.

For details on Steps 1-4 of this procedure, see the examples on the [!ndiskd.cxadapter](#) topic. For details on Step 5 of this procedure, see the examples on the [!ndiskd.netqueue](#) topic. In the following example, look for the handle for this NETTXQUEUE's ring buffer, fffffd1022d000000.

```
0: kd> !ndiskd.netqueue fffffd1022f512700

NETTXQUEUE 00002efdd0aed9a8
Ring buffer fffffd1022d000000

Switch to EC thread

Event Callbacks Function pointer Symbol (if available)
EvtQueueAdvance ffffff80034152af8 RtEthSample+2af8
EvtQueueArmNotification ffffff80034159a94 RtEthSample+9a94
EvtQueueCancel ffffff800341598d8 RtEthSample+98d8
```

By clicking on the handle for the ring buffer or by entering the **!ndiskd.netrb -handle** command on the command line, you can see details for this NET\_RING\_BUFFER, including how many elements it contains and the address of its Begin and End indices.

```
0: kd> !ndiskd.netrb fffffd1022d000000

NET_RING_BUFFER fffffd1022d000000

Number of elements 0x080
Owned by OS 0x080
Owned by Client 00000

Begin Index 0x078 (fffffd1022d003c40 - NET_PACKET)
Next Index 0x078 (fffffd1022d003c40 - NET_PACKET)
End Index 0x078 (fffffd1022d003c40 - NET_PACKET)

List all elements
```

To see this NET\_RING\_BUFFER's elements, either click the "List all elements" link at the bottom of its details or enter the **!ndiskd.netrb -dump** command on the command line. The following example has had the middle elements excised for brevity.

```
0: kd> !ndiskd.netrb fffffd1022d000000 -dump

[000] fffffd1022d000040 - NET_PACKET
[001] fffffd1022d0000c0 - NET_PACKET
[002] fffffd1022d000140 - NET_PACKET
[003] fffffd1022d0001c0 - NET_PACKET
[004] fffffd1022d000240 - NET_PACKET
[005] fffffd1022d0002c0 - NET_PACKET

...
[07b] fffffd1022d003dc0 - NET_PACKET
[07c] fffffd1022d003e40 - NET_PACKET
[07d] fffffd1022d003ec0 - NET_PACKET
[07e] fffffd1022d003fc40 - NET_PACKET
[07f] fffffd1022d003fc0 - NET_PACKET
```

# !ndiskd.netpacket

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.netpacket** extension displays information about a [NET\\_PACKET](#) structure.

For more information about the Network Adapter WDF Class Extension (NetAdapterCx), see [Network Adapter WDF Class Extension \(Cx\)](#).

```
!ndiskd.netpacket [-handle <xx>] [-basic] [-layout] [-checksum] [-data]
```

## Parameters

*-handle*

Required. Address of a NET\_PACKET.

*-basic*

Displays basic information.

*-layout*

Displays packet protocol layout.

*-checksum*

Displays packet checksum information.

*-data*

Dumps the payload memory.

## DLL

Ndiskd.dll

## Examples

**Note** See [Summary of Objects](#) to see a diagram explaining the relationship of the NET\_PACKET object with other objects in the NetAdapterCx.

To obtain a handle for a NET\_PACKET, follow these steps:

1. Run the [!ndiskd.netadapter](#) extension.
2. Click on the handle for a NetAdapter that has a NetAdapterCx driver installed.
3. Click the "More Information" link to the right of the NetAdapter's NETADAPTER object to run the [!ndiskd.cxadapter](#) extension.
4. Enter the [!ndiskd.cxadapter](#) command with the *-datapath* parameter to see that NETADAPTER's datapath queues.
5. Click on the handle for one of the datapath queues.
6. Click on the handle for that datapath queue's ring buffer.
7. Click on the "List all elements" link at the bottom of the ring buffer details to see the elements it contains.

For details on Steps 1-4 of this procedure, see the examples on the [!ndiskd.cxadapter](#) topic. For details on Step 5 of this procedure, see the examples on the [!ndiskd.netqueue](#) topic. For details on Steps 6-7 of this procedure, see the examples on the [!ndiskd.netrb](#) topic. In the following example, look for the handle for the first NET\_PACKET, fffffd1022d000040.

```
0: kd> !ndiskd.netrb fffffd1022d000000 -dump
```

```
[000] fffffd1022d000040 - NET_PACKET
[001] fffffd1022d0000c0 - NET_PACKET
[002] fffffd1022d000140 - NET_PACKET
[003] fffffd1022d0001c0 - NET_PACKET
[004] fffffd1022d000240 - NET_PACKET
[005] fffffd1022d0002c0 - NET_PACKET

...
[07b] fffffd1022d003dc0 - NET_PACKET
[07c] fffffd1022d003e40 - NET_PACKET
[07d] fffffd1022d003ec0 - NET_PACKET
[07e] fffffd1022d003f40 - NET_PACKET
[07f] fffffd1022d003fc0 - NET_PACKET
```

By clicking on the handle for this NET\_PACKET or by entering **!ndiskd.netpacket -handle** on the command line, you can see details for this NET\_PACKET, including the ring buffer that contains it, the datapath queue that contains its ring buffer, and the handle for its first fragment.

```
0: kd> !ndiskd.netpacket fffffd1022d000040
```

|                |                   |             |                    |
|----------------|-------------------|-------------|--------------------|
| NET_PACKET     | fffffd1022d000040 | Ring Buffer | fffffd1022d0000000 |
| First fragment | fffffd1022d000040 | NETTXQUEUE  | fffffd1022f512700  |
| Client Context | fffffd1022d000090 |             |                    |

```
Show protocol layout
Show checksum information
Dump data payload
```

You can now combine the basic description with any of the other **!ndiskd.netpacket** parameters, or all of them, to see specific information for this fragment. The following example uses all parameters.

```
0: kd> !ndiskd.netpacket fffffd1022d000040 -basic -layout -checksum -data

NET_PACKET fffffd1022d000040 Ring Buffer fffffd1022d000000
First fragment fffffd1022d000040 NETTXQUEUE fffffd1022f512700

Client Context fffffd1022d000090

Protocol Layout

Layer 2 Type ETHERNET
Header Length 0n14

Layer 3 Type IPV4_NO_OPTIONS
Header Length 0n20

Layer 4 Type UDP
Header Length 8

Checksum Information

Layer 2 TX_PASSTHROUGH
Layer 3 TX_REQUIRED
Layer 4 TX_PASSTHROUGH

Payload data

Fragment fffffd1022d000040
fffffd102303e8332 00 00 01 02 71 68 0a 89-be 39 e0 00 00 16 94 04 qh...9.....
fffffd102303e8342 00 00 22 00 fa 01 00 00-00 01 03 00 00 00 e0 00 ..".....
fffffd102303e8352 00 fc
```

# !ndiskd.netpacketfragment

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.netpacketfragment** extension displays information about a [NET\\_PACKET\\_FRAGMENT](#) structure.

For more information about the Network Adapter WDF Class Extension (NetAdapterCx), see [Network Adapter WDF Class Extension \(Cx\)](#).

```
!ndiskd.netpacketfragment [-handle <x>]
```

## Parameters

**-handle**

Required. Address of a NET\_PACKET\_FRAGMENT.

### DLL

Ndiskd.dll

## Examples

**Note** See [Summary of Objects](#) to see a diagram explaining the relationship of the NET\_PACKET object with other objects in the NetAdapterCx.

To obtain a handle for a NET\_PACKET, follow these steps:

1. Run the **!ndiskd.netadapter** extension.
2. Click on the handle for a NetAdapter that has a NetAdapterCx driver installed.
3. Click the "More Information" link to the right of the NetAdapter's NETADAPTER object to run the **!ndiskd.cxadAPTER** extension.
4. Enter the **!ndiskd.cxadAPTER** command with the *-datapath* parameter to see that NETADAPTER's datapath queues.
5. Click on the handle for one of the datapath queues.
6. Click on the handle for that datapath queue's ring buffer.
7. Click on the "List all elements" link at the bottom of the ring buffer details to see the elements it contains.
8. Click on one of the [NET\\_PACKET](#) objects in the ring buffer's list of elements.

For details on Steps 1-4 of this procedure, see the examples on the **!ndiskd.cxadAPTER** topic. For details on Step 5 of this procedure, see the examples on the **!ndiskd.netqueue** topic. For details on Steps 6-7 of this procedure, see the examples on the **!ndiskd.netrb** topic. For details on Step 8 of this procedure, see the examples on the **!ndiskd.netpacket** topic. In the following example, look for the handle for the first fragment of this NET\_PACKET, fffffd1022d000040.

```
0: kd> !ndiskd.netpacket fffffd1022d000040

 NET_PACKET fffffd1022d000040 Ring Buffer fffffd1022d000000
 First fragment fffffd1022d000040 NETTXQUEUE fffffd1022f512700

 Client Context fffffd1022d000090

 Show protocol layout
 Show checksum information
 Dump data payload
```

By clicking on the handle for the first fragment or by entering the **!ndiskd.netpacketfragment -handle** command on the command line, you can see details for this NET\_PACKET\_FRAGMENT, including its Virtual Address, capacity, and whether or not it is the last packet in the NET\_PACKET chain of fragments.

```
0: kd> !ndiskd.netpacketfragment fffffd1022d000040

 NET_PACKET_FRAGMENT fffffd1022d000040

 Virtual Address fffffd102303e82f8
 Capacity 0n92
 Valid Length 0n34
 Offset 0n58

 Last packet of chain
```

# !ndiskd.oid

5/31/2017 • 3 min to read • [Edit Online](#)

The **!ndiskd.oid** extension displays information about an NDIS OID request. If you run this extension with no parameters, !ndiskd will display a list of all pending OID requests on all miniports and filters. Each miniport or filter has at most one pending OID request and any number of queued OID requests.

Note that filters typically clone OID requests and pass the clone down. This means that even if a protocol issues a single OID request, there may be multiple instances of cloned requests: one in each filter and another in the miniport. **!ndiskd.oid** will show each clone separately, so you may see more pending OIDs than the protocol has actually issued.

```
!ndiskd.oid [-handle <xx>] [-legacyoid] [-nolimit] [-miniport <xx>]
```

## Parameters

*-handle*

Handle of an NDIS\_OID\_REQUEST

*-legacyoid*

Treats as a legacy NDIS\_REQUEST instead of an NDIS\_OID\_REQUEST.

*-nolimit*

Does not limit the number of pending OIDs that are displayed.

*-miniport*

Finds pending OID requests on this miniport's stack.

## DLL

Ndiskd.dll

## Remarks

**!ndiskd.oid** shows you a list of all the pending OIDs on the system at a time, so it can be very helpful in debugging system hangs or [0x9F bug check](#) situations (DRIVER\_POWER\_STATE\_FAILURE). For example, suppose analyzing a fictitious 0x9F bug check revealed that the system was hung on an IRP and was waiting for NDIS. In NDIS, IRPs from the OS are translated into OIDs, including power transitions, so by running **!ndiskd.oid** you could see that, in this example, a device at the bottom of the stack might have been clinging to an [OID\\_PNP\\_SET\\_POWER](#) and hung the rest of the stack. NDIS drivers should not pend an OID for more than one second, so you could then investigate why that device kept the OID pending for too long to try to solve the issue.

## Examples

To see an example of pending OIDS on a system that is running normally, set a breakpoint on a miniport's OID request handler routine (in the miniport's corresponding miniport driver). First, run the **!ndiskd.minidriver** command with no parameters to get a list of miniport drivers on the system. In this example output, look for the handle for the kdnic minidriver, fffffdf801418d650..

```
3: kd> !ndiskd.minidriver
fffffdf8015a98380 - tunnel
fffffdf801418d650 - kdnic
```

Click on the handle for the minidriver, then click on the "Handlers" link at the bottom of its details page to see the list of its handlers. You can alternatively enter the **!ndiskd.minidriver -handle -handlers** command. Once you have the list of the minidriver's handlers, look for the OidRequestHandler, whose handle is fffff80f1fd71c90 in this example.

```
2: kd> !ndiskd.minidriver fffffdf801418d650 -handlers
```

#### HANDLERS

|                               | Function pointer | Symbol (if available) |
|-------------------------------|------------------|-----------------------|
| NDIS Handler                  |                  |                       |
| InitializeHandlerEx           | fffff80f1fd78230 | bp                    |
| SetOptionsHandler             | fffff80f1fd72800 | bp                    |
| HaltHandlerEx                 | fffff80f1fd78040 | bp                    |
| ShutdownHandlerEx             | fffff80f1fd722c0 | bp                    |
|                               |                  |                       |
| CheckForHangHandlerEx         | fffff80f1fd72810 | bp                    |
| ResetHandlerEx                | fffff80f1fd72f70 | bp                    |
|                               |                  |                       |
| PauseHandler                  | fffff80f1fd78000 | bp                    |
| RestartHandler                | fffff80f1fd78940 | bp                    |
|                               |                  |                       |
| OidRequestHandler             | fffff80f1fd71c90 | bp                    |
| CancelOidRequestHandler       | fffff80f1fd722c0 | bp                    |
| DirectOidRequestHandler       | [None]           |                       |
| CancelDirectOidRequestHandler | [None]           |                       |
| DevicePnPEventNotifyHandler   | fffff80f1fd789a0 | bp                    |
|                               |                  |                       |
| SendNetBufferListsHandler     | fffff80f1fd71870 | bp                    |
| ReturnNetBufferListsHandler   | fffff80f1fd71b50 | bp                    |
| CancelSendHandler             | fffff80f1fd722c0 | bp                    |

Now either click on the "bp" link to the right of the OidRequestHandler or enter the **bp -handle** command with its handle to set a breakpoint on that routine. Next, type the **g** command to allow your debuggee target machine to run and hit the breakpoint you just set.

```
2: kd> bp fffff80f1fd71c90
2: kd> g
Breakpoint 1 hit
fffff80f`1fd71c90 448b4204 mov r8d,dword ptr [rdx+4]
```

Once you have triggered the breakpoint on a minidriver's OID request handler routine as shown by the previous example, you can run the **!ndiskd.oid** command to see a list of all the pending OIDs on the system.

```
1: kd> !ndiskd.oid

ALL PENDING OIDs

NetAdapter fffffdf80140c71a0 - Microsoft Kernel Debug Network Adapter
 Current OID OID_GEN_STATISTICS
 Filter fffffdf8014950c70 - Microsoft Kernel Debug Network Adapter-WFP Native MAC Layer
LightWeight Filter-0000
 Current OID OID_GEN_STATISTICS
 Filter fffffdf801494dc70 - Microsoft Kernel Debug Network Adapter-QoS Packet Scheduler-0000
 Current OID OID_GEN_STATISTICS
```

In this example, the OID pending is [OID\\_GEN\\_STATISTICS](#). When you look at the results of !ndiskd.oid, recall that filters clone OID requests and pass them down the stack, and OIDs typically get passed from filter to filter to miniport. Therefore, although it may look like there are three separate OID requests with the same name in this example, there is actually one logical operation taking place which was physically spread across 3 OIDs and on 3 drivers.

# !ndiskd.interfaces

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.interfaces** extension displays information about a network interface. If you run this extension with no parameters, !ndiskd will display a list of all network interfaces.

For more information about network interfaces, see [NDIS Network Interfaces](#).

```
!ndiskd.interfaces [-handle <x>] [-luid <x>]
```

## Parameters

### *-handle*

Handle of a network interface.

### *-luid*

NetLuid (Net Locally Unique Identifier) of a network interface.

## DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.interfaces** extension with no parameters to see a list of all network interfaces on the system. In this example, look for the Intel(R) 82579LM Gigabit Network Connection interface. Its handle is fffffdf80139f8a20.

```
1: kd> !ndiskd.interfaces
Interface
fffffdf801494fa20 - Microsoft Kernel Debug Network Adapter-WFP Native MAC Layer LightWeight Filter-0000
fffffdf801494c010 - Microsoft Kernel Debug Network Adapter-QoS Packet Scheduler-0000
fffffdf801494ba20 - Microsoft Kernel Debug Network Adapter-WFP 802.3 MAC Layer LightWeight Filter-0000
fffffdf80139b3a20 - Microsoft Kernel Debug Network Adapter
fffffdf80139f8a20 - Intel(R) 82579LM Gigabit Network Connection
fffffdf80139baa20 - WAN Miniport (IP)
fffffdf80139a4a20 - WAN Miniport (IPv6)
fffffdf80131d0010 - WAN Miniport (Network Monitor)
fffffdf80131cda20 - WAN Miniport (PPPOE)
fffffdf80139b6a20 - Software Loopback Interface 1
fffffdf80139b0a20 - Microsoft ISATAP Adapter
fffffdf80139ada20 - WAN Miniport (SSTP)
fffffdf80131cf010 - WAN Miniport (IKEv2)
fffffdf80139fea20 - WAN Miniport (L2TP)
fffffdf80139a7a20 - WAN Miniport (PPTP)
fffffdf80139aaa20 - Microsoft ISATAP Adapter #2
fffffdf80139fba20 - Teredo Tunneling Pseudo-Interface
```

By clicking on the handle for an interface or by entering the **!ndiskd.interfaces -handle** command, you can see the details about that interface, including its Identifier information and its current state. In this example, you can see that the Intel(R) 82579LM Gigabit Network Connection is an Ethernet connection (its ifAlias) and is in a MediaConnectUnknown state for its connection (as it has been reserved for use by the Windows kernel debugger).

```
1: kd> !ndiskd.interfaces fffffdf80139f8a20

INTERFACE

Ethernet

Ndis handle fffffdf80139f8a20
IfProvider fffffdf80131ca8d0 - The NDIS interface provider
Provider context fffffdf80139f8a20

ifType IF_TYPE_ETHERNET_CSMACD
Media type 802.3
Physical medium 802.3
Access type BROADCAST
Direction type SEND_AND_RECEIVE
Connection type DEDICATED

ifConnectorPresent No

Network fffffdf80139b8900 - [Unnamed network]
Compartment fffffdf80139b9940 - Compartment #1
```

#### IDENTIFIERS

```
ifAlias Ethernet
ifDescr Intel(R) 82579LM Gigabit Network Connection
ifName (NET_LUID) 06:8001
ifPhysAddress 18-03-73-c1-e8-72

ifIndex 0n14
ifGuid cbddfde1-5570-4c65-9d47-52d63abce00c
```

#### STATE

```
Connected MediaConnectUnknown
ifOperStatus NOT_PRESENT

Link speed 0 [Speed is not applicable]
ifMtu 0
Duplex UnknownDuplex
```

Refer to RFC 2863 for definitions of many of these terms

# !ndiskd.ifprovider

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.ifprovider** extension displays information about an [NDIS interface provider](#) (IfProvider). If you run this extension with no parameters, !ndiskd will display a list of all registered NDIS interface providers.

```
!ndiskd.ifprovider [-handle <x>]
```

## Parameters

**-handle**

Handle of an IfProvider.

### DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.ifprovider** extension with no parameters to get a list of all registered IfProviders.

```
1: kd> !ndiskd.ifprovider
IfProvider
ffffd20d14334180 - wanarp
ffffd20d1264a950 - wfplwfs
ffffd20d11deae00 - The NDIS loopback provider
ffffd20d11deae70 - The NDIS interface provider
```

You can see from the previous example that the debuggee machine has four interface providers registered. Two of them are NDIS interface providers.

**Note** Interface providers are a generic concept and aren't required to be miniport drivers. While a miniport driver may choose to register as an interface provider if desired, most miniport drivers do not do so because NDIS has a built-in interface provider. The NDIS built-in interface provider automatically provides interfaces for every miniport driver, every Light-Weight Filter (LWF) module, and the loopback interface. For more information, see [NDIS interface provider](#).

The following example shows the details for the "wanarp" interface provider in the previous example, whose handle is fffffd20d14334180.

```
1: kd> !ndiskd.ifprovider fffffd20d14334180
```

#### IF PROVIDER

```
wanarp
Ndis handle fffffd20d14334180
```

#### INTERFACES

```
Interface
[No interfaces found]
```

#### HANDLERS

| Protocol handler   | Function pointer | Symbol (if available)           |
|--------------------|------------------|---------------------------------|
| QueryObjectHandler | fffff80d2f0414b0 | bp wanarp!WanNdisIfQueryHandler |
| SetObjectHandler   | fffff80d2f04bd10 | bp wanarp!WanNdisIfSetHandler   |

[Registering as an Interface Provider](#)

[Send comments about this topic to Microsoft](#)

# !ndiskd.ifstacktable

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ndiskd.ifstacktable** extension displays the network interface stack table (ifStackTable).

For more information about the interface stack table, see [Maintaining a Network Interface Stack](#).

```
!ndiskd.ifstacktable
```

## Parameters

This extension has no parameters.

### DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.ifstacktable** command to see the ifStackTable.

```
3: kd> !ndiskd.ifstacktable

INTERFACE STACK TABLE

 Lower interface Lower IfIndex Higher IfIndex Higher interface
 fffffdf80139b3a20 6 15 fffffdf801494fa20
 fffffdf801494fa20 15 16 fffffdf801494c010
 fffffdf801494c010 16 17 fffffdf801494ba20
```

NDIS maintains the stack table for NDIS miniport adapters, NDIS 5.x filter intermediate drivers, and NDIS filter modules, whereas [NDIS MUX Intermediate Drivers](#) drivers are required to specify the internal interface relationship between the virtual miniport interface and the protocol lower interface. Therefore, the ifStackTable could be useful for seeing the interface stack relationships in a system with more complicated MUX drivers installed.

Since there are no NDIS MUX Intermediate drivers installed on this example system, the ifStackTable only shows the stack relationships that NDIS has provided. In the following example, clicking on the handle for the Lower interface of the third row (handle fffffdf801494c010, Lower IfIndex 16) shows the interface for the QoS Packet Scheduler.

```
3: kd> !ndiskd.interface fffffdf801494c010
```

#### INTERFACE

```
[Zero-length string]

Ndis handle fffffdf801494c010
IfProvider fffffdf80131ca8d0 - The NDIS interface provider
NDIS filter fffffdf801494dc70 - Microsoft Kernel Debug Network Adapter-QoS Packet Scheduler-0000

ifType IF_TYPE_ETHERNET_CSMACD
Media type 802.3
Physical medium NdisPhysicalMediumOther
Access type BROADCAST
Direction type SEND_AND_RECEIVE
Connection type DEDICATED

ifConnectorPresent No

Network fffffdf80139b8900 - [Unnamed network]
Compartment fffffdf80139b9940 - Compartment #1
```

#### IDENTIFIERS

```
ifAlias [Zero-length string]
ifDescr Microsoft Kernel Debug Network Adapter-QoS Packet Scheduler-0000
ifName (NET_LUID) 06:01
ifPhysAddress 18-03-73-c1-e8-72

ifIndex 0n16
ifGuid fc2a0ae1-b103-11e6-b724-806e6f6e6963
```

#### STATE

```
Connected Connected
ifOperStatus DORMANT
ifOperStatusFlags DORMANT_PAUSED

Link speed 1000000000 (1 Gbps)
ifMtu 0n1500
Duplex FullDuplex
```

Refer to RFC 2863 for definitions of many of these terms

Continuing the same example, clicking the handle for the Higher interface of the third row (handle fffffdf801494ba20, Higher IfIndex 17) shows the interface for the WFP 802.3 MAC Layer LightWeight Filter.

```
3: kd> !ndiskd.interface fffffdf801494ba20
```

#### INTERFACE

```
[Zero-length string]

Ndis handle fffffdf801494ba20 [type it]
IfProvider fffffdf80131ca8d0 - The NDIS interface provider
NDIS filter fffffdf801494c670 - Microsoft Kernel Debug Network Adapter-WFP 802.3 MAC Layer
LightWeight Filter-0000

ifType IF_TYPE_ETHERNET_CSMACD
Media type 802.3
Physical medium NdisPhysicalMediumOther
Access type BROADCAST
Direction type SEND_AND_RECEIVE
Connection type DEDICATED

ifConnectorPresent No

Network fffffdf80139b8900 - [Unnamed network]
Compartment fffffdf80139b9940 - Compartment #1
```

#### IDENTIFIERS

```
ifAlias [Zero-length string]
ifDescr Microsoft Kernel Debug Network Adapter-WFP 802.3 MAC Layer LightWeight Filter-0000
ifName (NET_LUID) 06:02
ifPhysAddress 18-03-73-c1-e8-72

ifIndex 0n17
ifGuid fc2a0ae0-b103-11e6-b724-806e6f6e6963
```

#### STATE

```
Connected Connected
ifOperStatus DORMANT
ifOperStatusFlags DORMANT_PAUSED

Link speed 1000000000 (1 Gbps)
ifMtu 0n1500
Duplex FullDuplex
```

Refer to RFC 2863 for definitions of many of these terms

This shows that the WFP 802.3 MAC Layer LightWeight Filter sits above the QoS Packet Scheduler filter in the network interface stack. You can confirm this by running the [!ndiskd.netreport](#) extension, which shows you the network stack visually.

# !ndiskd.compartments

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.compartments** extension displays all network compartments.

```
!ndiskd.compartments
```

## Parameters

This extension has no parameters.

### DLL

Ndiskd.dll

## Remarks

Compartments are a way that NDIS manages interfaces. Third party interface providers only use the primary compartment, as described in the **CompartmentId** member of the [NDIS\\_BIND\\_PARAMETERS](#) structure.

## Examples

Run the **!ndiskd.compartments** extension to see a list of all network compartments. In this example, there is only one compartment (the primary one).

```
3: kd> !ndiskd.compartments
Compartment fffffdf80139b9940
ID 1
Loopback Network fffffdf80139b8900
Loopback Interface fffffdf80139b6a20
Networks:
 fffffdf80139b8900 [Unnamed network]
```

[NDIS\\_PACKET](#)

[Send comments about this topic to Microsoft](#)

# !ndiskd.pkt pools

5/31/2017 • 1 min to read • [Edit Online](#)

**Warning** This extension is for legacy NDIS 5.x drivers. The [NDIS\\_PACKET](#) structure and its associated architecture have been deprecated.

The **!ndiskd.pkt pools** extension displays a list of all allocated packet pools.

```
!ndiskd.pkt pools
```

## DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.pkt pools** extension to see a list of all allocated packet pools on the system. Note that the handles for the packet pools are not clickable, which means you can't explore further information about the packet pool. This is because NDIS does not use packet pools starting with NDIS 6.0, so these pools are allocated only for legacy drivers which may still be on older systems. The debuggee machine in this example does not have any legacy NDIS 5.x drivers installed so the packet pools are not used. This example is for illustrative purposes only.

```
3: kd> !ndiskd.pkt pools
Pool Allocator BlocksAllocated BlockSize PktsPerBlock PacketLength
fffffdf80131d58c0 ffffff80f1fbe3e8f 0x1 0x1000 0xa 0x190 ndis!DriverEntry+6af
fffffdf80131d5940 ffffff80f1fbe3e71 0x1 0x1000 0xa 0x180 ndis!DriverEntry+691
```

# !ndiskd.findpacket

5/31/2017 • 1 min to read • [Edit Online](#)

**Warning** This extension is for legacy NDIS 5.x drivers. The [NDIS\\_PACKET](#) structure and its associated architecture have been deprecated.

The **!ndiskd.findpacket** extension finds the specified packets.

```
!ndiskd.findpacket [-VirtualAddress] [-PoolAddress]
```

## Parameters

### *VirtualAddress*

Specifies a virtual address that is contained in the desired packet.

### *PoolAddress*

Specifies a pool address. All unreturned packets in this pool will be displayed.

## DLL

Ndiskd.dll

[Send comments about this topic to Microsoft](#)

# !ndiskd.vc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.vc** extension displays a Connection-Oriented (CoNDIS) virtual connection (VC).

```
!ndiskd.vc [-handle <x>]
```

## Parameters

*-handle*

Required. Handle of a VC pointer.

### DLL

Ndiskd.dll

## Remarks

For more information about CoNDIS, see [Connection-Oriented NDIS](#).

For more information about CoNDIS virtual connections, see [Virtual Connections](#).

## Examples

CoNDIS is used in certain situations such as connecting to a VPN, so running **!ndiskd.vc** will not show you results unless a miniport driver on your system has created and activated a CoNDIS virtual connection. The following example shows results from a machine that is connected to a VPN network. First, run the **!ndiskd.netadapter** extension with no parameters to see a list of miniports and miniport drivers on the system. In the following output, look for the miniport driver for the Marvell AVASTAR Wireless-AC Network Controller network adapter. Its handle is fffffc804af2e3710.

```
1: kd> !ndiskd.netadapter
 Driver NetAdapter Name
fffffc804af2e3710 fffffc804b9e6f1a0 Marvell AVASTAR Wireless-AC Network Controller
fffffc804b99b9020 fffffc804b9c301a0 WAN Miniport (Network Monitor)
fffffc804b99b9020 fffffc804b9c2a1a0 WAN Miniport (IPv6)
fffffc804b99b9020 fffffc804b8a8a1a0 WAN Miniport (IP)

# !ndiskd.af

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.af** extension displays a Connection-Oriented NDIS (CoNDIS) address family (AF).

```
!ndiskd.af [-handle <x>]
```

## Parameters

### *-handle*

Required. Handle of a CoNDIS address family.

### DLL

Ndiskd.dll

## Remarks

For more information about CoNDIS, see [Connection-Oriented NDIS](#).

For more information about CoNDIS address families, see [Address Families](#).

## Examples

CoNDIS is used in certain situations such as connecting to a VPN, so running **!ndiskd.af** will not show you results unless a miniport driver on your system has created and activated a CoNDIS virtual connection. The following example shows results from a machine that is connected to a VPN network. First, run the **!ndiskd.netadapter** extension with no parameters to see a list of miniports and miniport drivers on the system. In the following output, look for the miniport driver for the Marvell AVASTAR Wireless-AC Network Controller network adapter. Its handle is fffffc804af2e3710.

```
1: kd> !ndiskd.netadapter
 Driver NetAdapter Name
fffffc804af2e3710 fffffc804b9e6f1a0 Marvell AVASTAR Wireless-AC Network Controller

# !ndiskd.ndisref

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.ndisref** extension displays a debug log of a tracked reference count.

```
!ndiskd.ndisref [-handle <x>] [-tagtype <str>] [-stacks] [-tag <str>] [-refdebug]
```

## Parameters

*-handle*

Required. Handle of the refcount block.

*-tagtype*

Enum type of the tags.

*-stacks*

Includes stack traces (if available).

*-tag*

Limits display to a single tag.

*-refdebug*

Shows detailed debug log, if available.

## DLL

Ndiskd.dll

## Examples

The following example passes the handle of an NDIS miniport driver to the **!ndiskd.ndisref** extension to display the refcount block for that driver. First, run **!ndiskd.minidriver** with no parameters to see a list of all miniport drivers on the system. In the example output below, look for the handle for the kdnic driver, fffffdf801418d650.

```
3: kd> !ndiskd.minidriver
fffffdf8015a98380 - tunnel
fffffdf801418d650 - kdnic
```

Using the miniport driver's handle, enter the **!ndiskd.ndisref -handle** command to see the refcount block for this miniport driver. The following example has the middle of the refcount block excised for brevity.

```
3: kd> !ndiskd.ndisref fffffdf801418d650
```

#### REFCOUNT BLOCK

| Tag   | Number of references |             |
|-------|----------------------|-------------|
| 0n0   | 0n6293               | Show stacks |
| 0n1   | 0n1045               | Show stacks |

# !ndiskd.ndisevent

5/31/2017 • 2 min to read • [Edit Online](#)

**Note** Third party network driver developers are not expected to manually use this extension command. You can run it to see the information it displays but you are not able to reuse the details it provides in your driver.

The **!ndiskd.ndisevent** extension displays an NDIS debug event log.

```
!ndiskd.ndisevent [-handle <x>] [-tagtype <str>]
```

## Parameters

*-handle*

Required. Handle of the event log.

*-tagtype*

Enum type of the tags.

## DLL

Ndiskd.dll

## Examples

To see the output of the event log for a network adapter, !ndiskd provides a link to it in the State section of the **!ndiskd.netadapter** output. This is easier than the manual method of finding an event log's handle from a miniport block and using that to run the **!ndiskd.ndisevent** extension.

First, enter the **!ndiskd.netadapter** command with no parameters to see a list of network adapters and miniport drivers on the system. In the following example, look for the handle for the Marvell AVASTAR Wireless-AC Network Controller, fffffc804b9e6f1a0.

```
1: kd> !ndiskd.netadapter
Driver NetAdapter Name
fffffc804af2e3710 fffffc804b9e6f1a0 Marvell AVASTAR Wireless-AC Network Controller
fffffc804b99b9020 fffffc804b9c301a0 WAN Miniport (Network Monitor)
fffffc804b99b9020 fffffc804b9c2a1a0 WAN Miniport (IPv6)
fffffc804b99b9020 fffffc804b8a8a1a0 WAN Miniport (IP)
fffffc804ae9d7020 fffffc804b9ceb1a0 WAN Miniport (PPPOE)
fffffc804b9ca5900 fffffc804b9e601a0 WAN Miniport (PPTP)
fffffc804b99dc720 fffffc804b99b01a0 WAN Miniport (L2TP)
fffffc804b86581b0 fffffc804b9c6c1a0 WAN Miniport (IKEv2)
fffffc804ad4a7250 fffffc804b99651a0 WAN Miniport (SSTP)
fffffc804b11c4020 fffffc804b85821a0 Microsoft ISATAP Adapter
fffffc804b11c4020 fffffc804b71731a0 Microsoft ISATAP Adapter #2
fffffc804ad725020 fffffc804b05e71a0 Surface Ethernet Adapter #2
fffffc804b0bf0020 fffffc804b0c011a0 Bluetooth Device (Personal Area Network)
fffffc804aef695e0 fffffc804aed331a0 TAP-Windows Adapter V9
```

Now, click on the link for that NetAdapter or enter the **!ndiskd.netadapter -handle** command to see its details. Look for the "Show state history" link to the right of the Device PnP field, in the State section.

```
1: kd> !ndiskd.netadapter fffffc804b9e6f1a0
```

#### MINIPORT

```
Marvell AVASTAR Wireless-AC Network Controller

Ndis handle fffffc804b9e6f1a0
Ndis API version v6.50
Adapter context fffffc804af3b1100
Driver fffffc804af2e3710 - mrvlpcie8897 v1.0
Network interface fffffc804aea60a20

Media type 802.3
Physical medium NdisPhysicalMediumUnspecified
Device instance PCI\VEN_11AB&DEV_2B38&SUBSYS_045E0001&REV_00\4&379f07b2&0&00E0
Device object fffffc804b9e6f050 More information
MAC address c0-33-5e-13-22-f7
```

#### STATE

```
Miniport INITIALIZING
Device PnP ADDED Show state history
Datapath Normal
Operational status DOWN
Operational flags [No flags set]
Admin status ADMIN_UP
Media MediaConnectUnknown
Power D0
References 1 Show detail
Total resets 0
Pending OID None
Flags IN_INITIALIZE, NOT_BUS_MASTER, DEFAULT_PORT_ACTIVATED,
 NOT_SUPPORTS_MEDIA_SENSE, DOES_LOOPBACK, MEDIA_CONNECTED
PnP flags PM_SUPPORTED, RECEIVED_START, HARDWARE_DEVICE
```

#### WDI

```
This system supports WDI.
Learn more about the associated WDI state
```

#### BINDINGS

```
Protocol list Driver Open Context
No protocols are bound to this miniport

Filter list Driver Module Context
No filters are bound to this miniport
```

#### MORE INFORMATION

|                    |                         |
|--------------------|-------------------------|
| Driver handlers    | Task offloads           |
| Power management   | PM protocol offloads    |
| Pending OIDs       | Timers                  |
| Pending NBLs       | Receive side throttling |
| Wake-on-LAN (WoL)  | Packet filter           |
| Receive queues     | Receive filtering       |
| RSS                | NIC switch              |
| Hardware resources | Selective suspend       |
| NDIS ports         | WMI guids               |
| Diagnostic log     |                         |

Now you can click the "Show state history" link or use the net adapter's handle to enter the **!ndiskd.netadapter - handle -log** command, which will show you the PnP event log for this miniport's miniport driver.

```
1: kd> !ndiskd.netadapter fffffc804b9e6f1a0 -log

MINIPORT PM & PNP EVENTS

Event Timestamp (most recent event at bottom)

# !ndiskd.ndisstack

5/31/2017 • 1 min to read • [Edit Online](#)

**Note** Third party network driver developers are not expected to manually use this extension command. You can run it to see the information it displays but you are not able to reuse the details it provides in your driver.

The **!ndiskd.ndisstack** extension displays a debug stack trace.

```
!ndiskd.ndisstack [-handle <x>] [-statistics]
```

## Parameters

*-handle*

Required. Handle of the stack block.

*-statistics*

Shows debugging statistics.

## DLL

Ndiskd.dll

# !ndiskd.wdiadapter

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.wdiadapter** extension displays information about a WDI WiFi!CAdapter structure. If you run this extension with no parameters, !ndiskd will display a list of all WDI WiFi!CAdapter structures.

For more information about WDI miniport drivers, see the [WDI Miniport Driver Design Guide](#).

For more information about WDI miniport driver reference, see [WDI Miniport Driver Reference](#).

```
!ndiskd.wdiadapter [-handle <x>] [-pm] [-rcvfilter]
```

## Parameters

*-handle*

Handle of a CAdapter object.

*-pm*

Shows power management state and capabilities.

*-rcvfilter*

Shows receive filtering capabilities.

## DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.wdiadapter** extension with no parameters to see a list of all CAdapter objects, along with details for each of their WDI Adapters. In the following example, there is only one CAdapter structure. The handle for its associated WDI Adapter is fffffc804af396000.

```
1: kd> !ndiskd.wdiadapter
CAdapter
fffffc804af396000 - WDI Adapter

WDI ADAPTER

Object fffffc804af396000
Miniport fffffc804b9e6f1a0
WDI driver fffffc804b8ce7c40 - WDI MiniDriver
NetGuid 47cb3aa5-e29c-4628-80bd-5023c53fccc
Power D0

CCtlPlane fffffc804af396080
CTxMgr fffffc804af399790
```

#### DEVICE COMMANDS

```
Scheduler state DeviceCommandSchedulerStateInit
[No queued device commands found]
```

```
Device Command Scheduler
```

#### SERIALIZED JOBS

| Job               | State       | Type | Child                     |
|-------------------|-------------|------|---------------------------|
| fffffc804b9f33000 | StepPending |      | WiFiJobMiniportInitialize |

#### ACTIVE JOBS

| Job               | State       | Type | Child                     |
|-------------------|-------------|------|---------------------------|
| fffffc804b9f33000 | StepPending |      | WiFiJobMiniportInitialize |

#### EVENTS

```
Processing? No

Event Status Type
[No events found]
```

```
Event Queue
```

#### MORE INFORMATION

|                  |                   |
|------------------|-------------------|
| Power management | Receive filtering |
|------------------|-------------------|

Now you can either click on the "Power management" and "Receive filtering" links at the bottom of the CAdapter structure's description, or you can enter the **!ndiskd.wdiadapter -handle** command with either the *-pm* or *-rcvfilter* option. The following example shows output for the *-rcvfilter* option.

```
1: kd> !ndiskd.wdiadapter fffffc804af396000 -rcvfilter
```

# !ndiskd.wdminidriver

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.wdminidriver** extension displays information about one or more CMiniportDriver structures. If you run this extension with no parameters, !ndiskd will display a list of all CMiniportDriver structures.

For more information about WDI miniport drivers, see the [WDI Miniport Driver Design Guide](#).

For more information about WDI miniport driver reference, see [WDI Miniport Driver Reference](#).

```
!ndiskd.wdminidriver [-handle <x>] [-pm] [-rcvfilter]
```

## Parameters

*-handle*

Handle of a CMiniportDriver object.

*-basic*

Displays basic information about the miniport driver.

*-handlers*

Displays this driver's miniport handlers.

## DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.wdminidriver** extension with no parameters to see a list of all CMiniportDriver objects. In the following example, there is only one CMiniportDriver object. The handle of its WdiMiniDriver is fffffc804b8ce7c40.

```
1: kd> !ndiskd.wdminidriver
WdiMiniDriver Name
fffffc804b8ce7c40 - WDI MiniDriver
```

Click on the WdiMiniDriver's handle or enter the **!ndiskd.wdminidriver -handle** command to see details for this WDI miniport driver.

```
1: kd> !ndiskd.wdiminidriver fffffc804b8ce7c40
```

#### WDI MINIPORT DRIVER

|                  |                                  |
|------------------|----------------------------------|
| Object           | fffffc804b8ce7c40                |
| DRIVER_OBJECT    | fffffc804b90a4ac0                |
|                  |                                  |
| Ndis API version | v6.50                            |
| NDIS driver      | fffffc804af2e3710 - mrvlpcie8897 |
| Driver version   | v1.0                             |
| WDI API version  | v1.0.1                           |

#### Handlers

Now you can click the "Handlers" link at the bottom of the WDI Miniport Driver's details, or you can use the handle to enter the **!ndiskd.wdiminidriver -handle -handlers** command, to see a list of all this WDI Miniport Driver's handlers.

```
1: kd> !ndiskd.wdiminidriver fffffc804b8ce7c40 -handlers
```

#### HANDLERS

| Miniport Handler              | Function pointer  | Symbol (if available)                  |
|-------------------------------|-------------------|----------------------------------------|
| InitializeHandlerEx           | [None]            |                                        |
| SetOptionsHandler             | fffffc80965e8cae0 | mrvlpcie8897!wlan_cmd_queue_deinit     |
| UnloadHandler                 | fffffc80965e71a08 | mrvlpcie8897!MPUnload                  |
| HaltHandlerEx                 | [None]            |                                        |

# !ndiskd.ndisrwllock

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.ndisrwllock** extension displays information about an **NDIS\_RW\_LOCK\_EX** lock structure.

```
!ndiskd.ndisrwllock [-handle <x>]
```

## Parameters

**-handle**

Required. Handle of the lock structure.

### DLL

Ndiskd.dll

## Examples

Use the **!ndiskd.ndisrwllock** extension if you create your own RW lock and would want to inspect it. To obtain the handle for an RW lock, use the **poi** command to dereference the address of your driver's lock. The following snippet shows how to look at a lock that the TCPIP protocol was using at the time of the example.

```
0: kd> !ndiskd.ndisrwllock poi(tcpip!gAleHashtableLock)

NDIS READ-WRITE LOCK

Allocated by [NDIS generic object]
Exclusive access Not acquired
Read-only access 0 references

Set a breakpoint on acquire/release
```

To observe the driver using this RW lock, click on the "Set a breakpoint on acquire/release" link at the bottom of the RW lock's details. After setting the breakpoint, enter the **g** command to let the debuggee machine run and hit the breakpoint.

```
0: kd> ba r4 fffffe00bc3fc22f8
0: kd> g
Breakpoint 0 hit
nt!KeTestSpinLock+0x3:
fffff802`0d69eb53 4885c0 test rax,rax
```

Now you can re-run the same **!ndiskd.ndisrwllock** command to see that this RW lock has one Read-only access reference.

```
0: kd> !ndiskd.ndisrwlock poi(tcpip!gAleHashtableLock)
```

NDIS READ-WRITE LOCK

|                  |                       |
|------------------|-----------------------|
| Allocated by     | [NDIS generic object] |
| Exclusive access | Not acquired          |
| Read-only access | 1 reference           |

Set a breakpoint on acquire/release

# !ndiskd.ndisslot

5/31/2017 • 1 min to read • [Edit Online](#)

**Note** Third party network driver developers are not expected to manually use this extension command. You can run it to see the information it displays but you are not able to reuse the details it provides in your driver.

The **!ndiskd.ndisslot** extension displays the contents of an NDIS per-processor variable. If you run this extension with no parameters, !ndiskd will display a list of all NDIS per-processor variables on the system.

```
!ndiskd.ndisslot [-handle <x>] [-itemtype <str>]
```

## Parameters

*-handle*

Handle of the slot.

*-itemtype*

Type of the value stored in the slot.

## DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.ndisslot** extension with no parameters to see a list of all per-processor slot variables. The following example output has excised the middle portion of the list for brevity.

```
1: kd> !ndiskd.ndisslot
Per-processor slot Summary of contents
fffffc804ae060000 - NDrw All values are zero
fffffc804ae060008 - NDrw All values are zero
fffffc804ae060010 - NDrw All values are zero
fffffc804ae060018 - NDrw All values are zero
fffffc804ae060020 - NDrw All values are zero
fffffc804ae060028 - NDrw All values are zero
fffffc804ae060030 - NDrw All values are zero
fffffc804ae060038 - NDrw All values are zero
fffffc804ae060040 - NDrw All values are zero
fffffc804ae060048 - NDrw All values are zero

...
fffffc804ae060910 - NDtk All values are zero
fffffc804ae060918 - NDtk All values are zero
fffffc804ae060920 - tsR All values are non-zero
fffffc804ae060928 - NDrw All values are zero
fffffc804ae060930 - NDtk All values are zero
fffffc804ae060938 - NDtk All values are zero
fffffc804ae060940 - NDtk All values are zero
fffffc804ae060948 - NDtk All values are zero
fffffc804ae060950 - NDrw All values are zero
fffffc804ae060958 - NDrw All values are zero

Statistics
Descriptors 1
Total slots 512
Slots available 275
Slots used 237
Efficiency 46%
```

Clicking on one of the handles for the per-processor slot variables will show you the details for that variable. The following example uses the handle fffffc804ae060920 for the tsR variable, from the previous example.

```
1: kd> !ndiskd.ndisslot fffffc804ae060920
Processor Slot value
00 00000006
01 00000006
02 00000006
03 00000006
```

## !ndiskd.dbglevel

The **!ndiskd.dbglevel** extension displays and optionally changes the current NDIS debug level.

### Warning

**!ndiskd.dbglevel** has been superceded by WPP (Windows software trace preprocessor) and Driver Verifier. !ndiskd will give you the following warning if your target system does not support **!ndiskd.dbglevel**.

```
0: kd> !ndiskd.dbglevel
This target does not support tracing through !ndiskd.dbglevel or
!ndiskd.dbgsystems.
Learn how to collect traces with WPP
```

If you click on the link at the bottom of the warning, !ndiskd will give you more information.

```
0: kd> !ndiskd.help wpptracing
WPP traces are fast, flexible, and detailed. Plus, starting with Windows 8
and Windows Server 2012, you can automatically decode NDIS traces using the
symbol file. Just point TraceView (or tracepdb.exe) at NDIS.PDB, and it
will be able to get all the TMFs it needs to trace NDIS activity.

If you would like traces to be printed in the debugger window, you use the
!wmitrace extension. For example, you might enable traces with this:

!wmitrace.searchpath c:\path\to\TMF\files
!wmitrace.start ndis -kd
!wmitrace.enable ndis {DD7A21E6-A651-46D4-B7C2-66543067B869} -level 4 -flag 0x31f3
```

For more information about WPP, see [WPP Software Tracing](#).

For more information about Driver Verifier, see [Driver Verifier](#).

For more information about WMI tracing, see [WMI Tracing Extensions \(Wmitrace.dll\)](#).

```
!ndiskd.dbglevel [-level <str>]
```

## Parameters

*-level*

The level of debugging verbosity. Possible values are:

- NONE - disables debug tracing
- FATAL - enables fatal errors to be printed
- ERROR - enables errors to be printed
- WARN - enables warnings to be printed
- INFO - enables informational messages to be printed
- VERBOSE - enables all debug traces to be printed

## DLL

Ndiskd.dll

## Remarks

This extension applies to checked NDIS.sys only. To check the build info of NDIS.sys, run the [!ndiskd.ndis](#) extension.

# !ndiskd.dbgsystems

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.dbgsystems** extension displays and optionally changes the NDIS subsystems that have debug traces enabled.

## Warning

**!ndiskd.dbgsystems** has been superceded by WPP (Windows software trace preprocessor) and Driver Verifier. !ndiskd will give you the following warning if your target system does not support **!ndiskd.dbgsystems**.

```
0: kd> !ndiskd.dbgsystems
This target does not support tracing through !ndiskd.dbglevel or
!ndiskd.dbgsystems.
Learn how to collect traces with WPP
```

If you click on the link at the bottom of the warning, !ndiskd will give you more information.

```
0: kd> !ndiskd.help wpptracing
WPP traces are fast, flexible, and detailed. Plus, starting with Windows 8
and Windows Server 2012, you can automatically decode NDIS traces using the
symbol file. Just point TraceView (or tracepdb.exe) at NDIS.PDB, and it
will be able to get all the TMFs it needs to trace NDIS activity.

If you would like traces to be printed in the debugger window, you use the
!wmitrace extension. For example, you might enable traces with this:

!wmitrace.searchpath c:\path\to\TMF\files
!wmitrace.start ndis -kd
!wmitrace.enable ndis {DD7A21E6-A651-46D4-B7C2-66543067B869} -level 4 -flag 0x31f3
```

For more information about WPP, see [WPP Software Tracing](#).

For more information about Driver Verifier, see [Driver Verifier](#).

For more information about WMI tracing, see [WMI Tracing Extensions \(Wmitrace.dll\)](#).

```
!ndiskd.dbgsystems [-subsystem <any>]
```

## Parameters

*-subsystem*

The subsystem to toggle.

If multiple components are selected, separate them with spaces. If a previously-selected component is repeated, its debug monitoring will be toggled off. The following values are possible:

| Value | Meaning                        |
|-------|--------------------------------|
| INIT  | Traces adapter initialization. |

|           |                                                       |
|-----------|-------------------------------------------------------|
| CONFIG    | Traces adapter configuration.                         |
| SEND      | Traces sending data over the network.                 |
| RECV      | Traces receiving data from the network.               |
| PROTOCOL  | Traces protocol operations.                           |
| BIND      | Traces binding operations.                            |
| BUS_QUERY | Traces bus queries.                                   |
| REGISTRY  | Traces registry operations.                           |
| MEMORY    | Traces memory management.                             |
| FILTER    | Traces filter operations.                             |
| REQUEST   | Traces requests.                                      |
| WORK_ITEM | Traces work-item operations.                          |
| PNP       | Traces Plug and Play operations.                      |
| PM        | Traces Power Management operations.                   |
| OPEN      | Traces operations that open reference objects.        |
| LOCKS     | Traces locking operations.                            |
| RESET     | Traces resetting operations.                          |
| WMI       | Traces Windows Management Instrumentation operations. |
| NDIS_CO   | Traces Connection-Oriented NDIS.                      |
| REFERENCE | Traces reference operations.                          |

## DLL

## Remarks

This extension applies to checked NDIS.sys only. To check the build info of NDIS.sys, run the [!ndiskd.ndis](#) extension.

# !ndiskd.ndiskdversion

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ndiskd.ndiskdversion** extension displays information about !ndiskd itself.

```
!ndiskd.ndiskdversion
```

## Parameters

This extension has no parameters.

### DLL

Ndiskd.dll

## Examples

The following example shows output for **!ndiskd.ndiskdversion**.

```
1: kd> !ndiskd.ndiskdversion
NDISKD Version 17.01.00 (NDISKD codename "All your WDF are belong to us")
Build Release
Debugger CPU AMD64
NDIS symbols Private More info
Hyperlinks (DML) Enabled
Unicode Enabled
Debug NDISKD Enabled
```

**[NDIS extensions \(Ndiskd.dll\)](#)**

**[!ndiskd.help](#)**

[Send comments about this topic to Microsoft](#)

# !ndiskd.netreport

5/31/2017 • 3 min to read • [Edit Online](#)

The **!ndiskd.netreport** extension generates a visual report of the entire network stack. The report **!ndiskd.netreport** generates is an HTML file, and it will give you a link to its location. The HTML file contains detailed information about the network stack, so if you need to share it for analysis you can email it instead of having to send a large crash dump file.

```
!ndiskd.netreport [-outputpath <str>] [-jsononly]
```

## Parameters

*-outputpath*

Specifies where to write the report file.

*-jsononly*

Only writes the raw data, no HTML.

## DLL

Ndiskd.dll

## Examples

Run the **!ndiskd.netreport** extension to draw a box diagram of your network stack.

```
1: kd> !ndiskd.netreport

NETWORK STACK REPORT

Want more stuff? Rerun with the -verbose flag

Report was saved to C:\Users*****\AppData\Local\Temp\NKDFE9F.html
View the report Send in email
```

Click the "View the report" link at the bottom to see the report generated. The following image shows a net report generated from a crash dump file. Each vertical stack is a network adapter, broken down into layers showing the components of the stack. The color of each box is generated by hashing the name of the component, which means the same components will render with the same color every time you run the report. This means you can easily pick out a particular driver or adapter if you are debugging an issue with it.

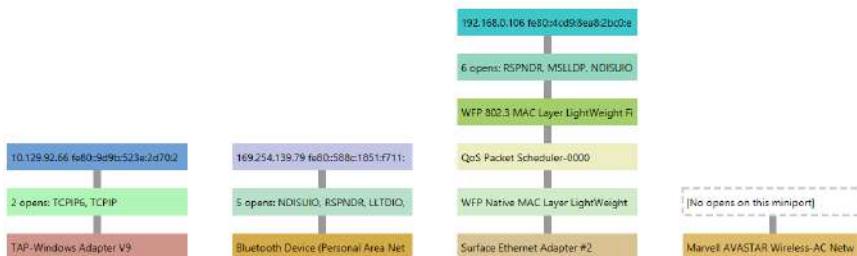

## NETWORK DEBUG REPORT

OVERVIEW

SYSTEM

SUMMARIES

[Help](#)

Show hidden miniports  Show NDIS filters  Show IP addresses

As a comparison, the following image shows a net report generated from an active system instead of a crash dump file. Note that there are two more options at the bottom of the HTML page to "Show data flows" and "Simulate packets," and there is a fourth tab at the top of the report for "Data flows." These options appeared because the debuggee machine had NBL tracking enabled, which lets **!ndiskd.netreport** parse the NBL tracking log to display the information visually. If NBL tracking is not turned on, these options will not appear. For more information about NBL tracking and the NBL log, see [!ndiskd.nbllog](#).

By checking the "Show data flows" box, you can see the paths where the data is flowing. By checking the "Simulate packets" box, you can see animated circles moving up and down the data flow paths. Each circle represents a network packet.

## NETWORK DEBUG REPORT

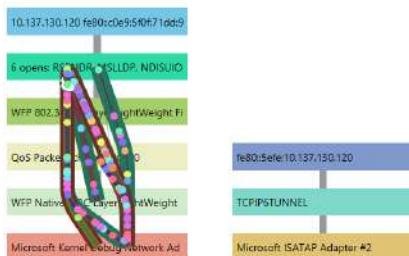

OVERVIEW

SYSTEM

SUMMARIES

DATA FLOWS

[Help](#)

Show hidden miniports  Show NDIS filters  Show IP addresses  Show data flows  Simulate packets

This second example from an active system also shows another difference from the first example, which used a crash dump file. The target debuggee machine in the second example was provisioned for kernel debugging over a network, so you can see the network adapter on the stack with the data flows is the Microsoft Kernel Debug Network Adapter. This adapter is usually hidden unless kernel debugging has been enabled on the debuggee machine. In reality, the Kernel Debug Network Adapter has reserved the machine's Ethernet adapter for the debug session, so traffic is flowing over Ethernet.

The ability to visualize the network stack and see where traffic is flowing can enable you to quickly identify where a problem might be. This can be particularly helpful for virtual switches or servers, which have more complicated network diagrams than the previous examples. For example, on a Windows Server that uses NIC Teaming, you can see if multiple network stacks cross each other to balance the traffic load and identify if there is an issue at the bottom of one stack that is affecting another stack. To see an example of a network debug report that shows this, see [Debugging the Network Stack](#). For more information about NIC Teaming, see [Using NIC Teaming for Network Subsystem Performance](#).

**!ndiskd.netreport** also has other tabs at the top of the page for System, Summaries, and Data Flows (if applicable). These tabs contain further useful information about the state of the network stack. The following image shows the Network Interfaces tab, under the Summaries tab. The table in this tab lets you see more information about the names and identifiers for the network interfaces in the system.

| NETWORK DEBUG REPORT |          |                                       |  |                                                                                     |      |            |
|----------------------|----------|---------------------------------------|--|-------------------------------------------------------------------------------------|------|------------|
| OVERVIEW             |          | SYSTEM                                |  | SUMMARIES                                                                           |      | DATA FLOWS |

+ Note that the !IfIndex changes each time the network interface is started (or the computer is rebooted). Avoid using the !IfIndex as a permanent identifier.

The Data flows tab, which appears if NBL tracking was enabled on the target system, shows a table of traffic events and details about each one. The following image shows the Data flows tab from the active system in the second example debug report described previously.

# RPC Extensions (Rpcexts.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands that are useful for debugging Microsoft Remote Procedure Call (RPC) can be found in `Rpcexts.dll`.

The Windows 2000 version of this extension DLL appears in the `w2kfre` and `w2kchk` directories. The Windows XP and later version of this extension DLL appear in the `winxp` directory.

For more information about how to use these extensions, see [Using the RPC Debugger Extensions](#).

[Send comments about this topic to Microsoft](#)

# !rpcexts.checkrpcsym

5/26/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.checkrpcsym** extension command is obsolete; the output from the debugger should be sufficient to diagnose any RPC symbol problems.

[Send comments about this topic to Microsoft](#)

# !rpcexts.eeinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.eeinfo** extension displays the extended error information chain.

```
!rpcexts.eeinfo EEInfoAddress
```

## Parameters

### *EEInfoAddress*

Specifies the address of the extended error information.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension displays the contents of all records in the extended error information chain.

The records are displayed in order, with the most recent records first. The records are separated by a line of dashes.

Here is an example (in which there is only one record):

```
0:001> !rpcexts.eeinfo 0xb015f0
Computer Name: (null)
ProcessID: 708 (0x2C4)
System Time is: 3/21/2000 4:3:0:264
Generating component: 8
Status: 14
Detection Location: 311
Flags:
Parameter 0:(Long value) : -30976 (0xFFFF8700)
Parameter 1:(Long value) : 16777343 (0x100007F)
```

If the chain is very long and you wish to see only one record, use **!rpcexts.eerecord** instead.

[Send comments about this topic to Microsoft](#)

# !rpcexts.eerecord

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.eerecord** extension displays the contents of an extended error information record.

```
!rpcexts.eerecord EERecordAddress
```

## Parameters

### *EERecordAddress*

Specifies the address of the extended error record.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension displays the contents of one extended error information record in the debugger. In most cases, it is easier to use **!rpcexts.eeinfo**, which displays the whole chain. If the chain is very long and you wish to see only one record, use **!eerecord** instead.

Here is an example:

```
0:001> !rpcexts.eerecord 0xb015f0
Computer Name: (null)
ProcessID: 708 (0x2C4)
System Time is: 3/21/2000 4:3:0:264
Generating component: 8
Status: 14
Detection Location: 311
Flags:
Parameter 0:(Long value) : -30976 (0xFFFF8700)
Parameter 1:(Long value) : 16777343 (0x100007F)
```

[Send comments about this topic to Microsoft](#)

# !rpcexts.getcallinfo

5/31/2017 • 3 min to read • [Edit Online](#)

The **!rpcexts.getcallinfo** extension searches the system's RPC state information for server-side call (SCALL) information.

```
!rpcexts.getcallinfo [CallID | 0 [IfStart | 0 [ProcNum | 0xFFFF [ProcessID|0]]]]
!rpcexts.getcallinfo -?
```

## Parameters

### *CallID*

Specifies the call ID. This parameter is optional; include it if you only want to display calls matching a specific *CallID* value.

### *IfStart*

Specifies the first DWORD of the interface UUID on which the call was made. This parameter is optional; include it if you only want to display calls matching a specific *IfStart* value.

### *ProcNum*

Specifies the procedure number of this call. (The RPC Run-Time identifies individual routines from an interface by numbering them by position in the IDL file -- the first routine in the interface is 0, the second 1, and so on.)

### *ProcessID*

Specifies the process ID (PID) of the server process that owns the calls you want to display. This parameter is optional; omit it if you want to display calls owned by multiple processes.

### -?

Displays some brief Help text for this extension in the Command Prompt window.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension can only be used with CDB or with user-mode WinDbg.

The parameters are parsed from left to right. To skip a parameter, supply the value 0. There is one exception to this rule: the *ProcNum* parameter is skipped by supplying the value 0xFFFF.

Here is an example:

```

0:002> !rpcexts.getcallinfo
Searching for call info ...
PID CELL ID ST PNO IFSTART TIDNUMBER CALLFLAG CALLID LASTTIME CONN/CLN

# !rpcexts.getclientcallinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.getclientcallinfo** extension searches the system's RPC state information for client call (CCALL) information.

```
!rpcexts.getclientcallinfo [CallID | 0 [IfStart | 0 [ProcNum | 0xFFFF [ProcessID|0]]]]
!rpcexts.getclientcallinfo -?
```

## Parameters

### *CallID*

Specifies the call ID. This parameter is optional; include it if you only want to display calls matching a specific *CallID* value.

### *IfStart*

Specifies the first DWORD of the interface UUID on which the call was made. This parameter is optional; include it if you only want to display calls matching a specific *IfStart* value.

### *ProcNum*

Specifies the procedure number of this call. (The RPC Run-Time identifies individual routines from an interface by numbering them by position in the IDL file -- the first routine in the interface is 0, the second 1, and so on.) This parameter is optional; include it if you only want to display calls matching a specific *ProcNum* value.

### *ProcessID*

Specifies the process ID (PID) of the client process that owns the calls you want to display. This parameter is optional; omit it if you want to display calls owned by multiple processes.

### **-?**

Displays some brief Help text for this extension in the Command Prompt window.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension can only be used with CDB or with user-mode WinDbg. It is only available if full RPC state information is being gathered.

Here is an example:

```
0:002> !rpcexts.getclientcallinfo
Searching for call info ...
PID CELL ID PNO IFSTART TIDNUMBER CALLID LASTTIME PS CLTNUMBER ENDPOINT

03d4 0000.0001 0000 19bb5061 0000.0000 00000001 0004ca9b 07 0000.0002 1118
```

For a similar example using the DbgRpc tool, see [Get RPC Client Call Information](#).

[Send comments about this topic to Microsoft](#)

# !rpcexts.getdbgcell

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.getdbgcell** extension displays RPC state information for the specified cell.

```
!rpcexts.getdbgcell ProcessID CellID1.CellID2
!rpcexts.getdbgcell -?
```

## Parameters

*ProcessID*

Specifies the process ID (PID) of the process whose server contains the desired cell.

*CellID1.CellID2*

Specifies the number of the cell to be displayed.

**-?**

Displays some brief Help text for this extension in the Command Prompt window.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension can only be used with CDB or with user-mode WinDbg.

Here is an example:

```
0:002> !rpcexts.getdbgcell c4 0.19
Getting cell info ...
Call
Status: Active
Procedure Number: 11
Interface UUID start (first DWORD only): 82273FDC
Call ID: 0x0 (0)
Servicing thread identifier: 0x0.3E
Call Flags: cached, LRPC
Last update time (in seconds since boot):1453.459 (0x5AD.1CB)
Caller (PID/TID) is: d0.1ac (208.428)
```

For a similar example using the DbgRpc tool, see [Get RPC Cell Information](#).

[Send comments about this topic to Microsoft](#)

# !rpcexts.getendpointinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.getendpointinfo** extension searches the system's RPC state information for endpoint information.

```
!rpcexts.getendpointinfo [EndpointName]
!rpcexts.getendpointinfo -?
```

## Parameters

### *EndpointName*

Specifies the number of the endpoint to be displayed. If omitted, the endpoints for all processes on the system are displayed.

### -?

Displays some brief Help text for this extension in the Command Prompt window.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension can only be used with CDB or with user-mode WinDbg.

Here is an example:

```

# !rpcexts.getthreadinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.getthreadinfo** extension searches the system's RPC state information for thread information.

```
!rpcexts.getthreadinfo ProcessID [ThreadID]
!rpcexts.getthreadinfo -?
```

## Parameters

### *ProcessID*

Specifies the process ID (PID) of the process containing the desired thread.

### *ThreadID*

Specifies the thread ID of the thread to be displayed. If omitted, all threads in the specified process will be displayed.

### **-?**

Displays some brief Help text for this extension in the Command Prompt window.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension can only be used with CDB or with user-mode WinDbg.

Here is an example:

```
0:002> !rpcexts.getthreadinfo 26c
Searching for thread info ...
PID CELL ID ST TID LASTTIME

026c 0000.0002 01 000003c4 0004caa5
026c 0000.0005 03 00000254 0004ca9b
```

For a similar example using the DbgRpc tool, see [Get RPC Thread Information](#).

[Send comments about this topic to Microsoft](#)

# !rpcexts.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.help** extension displays a Help text in the Command Prompt window showing all Rpcexts.dll extension commands.

```
!rpcexts.help
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Rpcexts.dll |
| <b>Windows XP and later</b> | Rpcexts.dll |

[Send comments about this topic to Microsoft](#)

# !rpcexts.rpcreadstack

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.rpcreadstack** extension reads an RPC client-side stack and retrieves the call information.

```
!rpcexts.rpcreadstack ThreadStackPointer
```

## Parameters

### *ThreadStackPointer*

Specifies the pointer to the thread stack.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

For a common use of this extension, see [Analyzing a Stuck Call Problem](#).

Here is an example:

```
0:001> !rpcexts.rpcreadstack 68fba4
CallID: 1
IfStart: 19bb5061
ProcNum: 0
 Protocol Sequence: "ncacn_ip_tcp" (Address: 00692ED8)
 NetworkAddress: "" (Address: 00692F38)
 Endpoint: "1120" (Address: 00693988)
```

[Send comments about this topic to Microsoft](#)

# !rpcexts.rpctime

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.rpctime** extension displays the current system time.

```
!rpcexts.rpctime
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Rpcexts.dll |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Remarks

This extension can only be used with CDB or with user-mode WinDbg.

Here is an example:

```
0:001> !rpcexts.rpctime
Current time is: 059931.126 (0x00ea1b.07e)
```

[Send comments about this topic to Microsoft](#)

# !rpcexts.thread

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rpcexts.thread** extension displays the per-thread RPC information.

This extension command should not be confused with the [.thread \(Set Register Context\)](#) command or the [!thread](#) (!kdextx86.thread and !kdexts.thread) extension.

```
!rpcexts.thread TEB
```

## Parameters

### TEB

Specifies the address of the thread environment block (TEB).

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Rpcexts.dll |
| <b>Windows XP and later</b> | Rpcexts.dll |

## Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

## Remarks

This extension displays the per-thread RPC information. A field in the per-thread RPC information is the extended error information for this thread.

Here is an example:

```
0:001> !rpcexts.thread 7ffdd000
RPC TLS at 692e70

# ACPI Extensions (Acpikd.dll and Kdexts.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands that are useful for debugging ACPI (Advanced Configuration and Power Interface) BIOS code can be found in Acpikd.dll and Kdexts.dll.

The Windows 2000 versions of these extension commands appear in the Acpikd.dll module located in the W2kfre and W2kchk directories. Note that this extension module has an internal build number of 2179, while Windows 2000 has a build number of 2195. You should ignore the resulting version mismatch errors.

For Windows XP and later versions of Windows, some of the ACPI debugging extensions can be found in Winxp\Acpikd.dll, while others can be found in Winxp\Kdexts.dll.

[Send comments about this topic to Microsoft](#)

# !acpicache

5/31/2017 • 1 min to read • [Edit Online](#)

The **!acpicache** extension displays all of the Advanced Configuration and Power Interface (ACPI) tables cached by the HAL.

```
!acpicache [DisplayLevel]
```

## Parameters

### *DisplayLevel*

Specifies the detail level of the display. This value is either 0 for an abbreviated display or 1 for a more detailed display. The default value is 0.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Kdexts.dll  |

## Additional Information

For information about the ACPI, see the Microsoft Windows Driver Kit (WDK) documentation, the Windows SDK documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These books and resources may not be available in some languages and countries.) Also see [ACPI Debugging](#) for information about other extensions that are associated with the ACPI.

[Send comments about this topic to Microsoft](#)

# !acpiinf

5/31/2017 • 1 min to read • [Edit Online](#)

The **!acpiinf** extension displays information on the configuration of the Advanced Configuration and Power Interface (ACPI), including the location of system tables and the contents of the ACPI fixed feature hardware.

```
!acpiinf
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Kdexts.dll  |

## Additional Information

For information about the ACPI, see the Microsoft Windows Driver Kit (WDK) documentation, the Windows SDK documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These books and resources may not be available in some languages and countries.) Also see [ACPI Debugging](#) for information about other extensions that are associated with the ACPI.

[Send comments about this topic to Microsoft](#)

# !acpiirqarb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!acpiirqarb** extension displays the contents of the Advanced Configuration and Power Interface (ACPI) IRQ arbiter structure, which contains the configuration of I/O devices to system interrupt controller inputs and processor interrupt dispatch table (IDT) entries.

```
!acpiirqarb
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Kdexts.dll  |

## Additional Information

For information about the ACPI, see the Microsoft Windows Driver Kit (WDK) documentation, the Windows SDK documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These books and resources may not be available in some languages and countries.) Also see [ACPI Debugging](#) for information about other extensions that are associated with the ACPI.

# !acpikd.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!acpikd.help** extension displays a Help text in the Debugger Command window showing all Acpikd.dll extension commands.

```
!acpikd.help
```

## DLL

|                             |            |
|-----------------------------|------------|
| <b>Windows 2000</b>         | Acpikd.dll |
| <b>Windows XP and later</b> | Acpikd.dll |

## Additional Information

For more information, see [ACPI Debugging](#).

[Send comments about this topic to Microsoft](#)

# !amli ?

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli ?** extension displays some Help text in the Debugger Command window for the **!amli** extension commands.

## Syntax

```
!amli ? [Command]
```

## Parameters

### *Command*

Specifies the **!amli** command whose help is to be displayed. For example, **!amli ? set** displays help for the **!amli set** command. If *Command* is omitted, a list of all commands is displayed.

### **DLL**

Kdexts.dll

### **Additional Information**

For information about related commands and their uses, see [The AMLI Debugger](#).

[Send comments about this topic to Microsoft](#)

# !amli bc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli bc** extension permanently clears an AML breakpoint.

## Syntax

```
!amli bc Breakpoint
!amli bc *
```

## Parameters

### *Breakpoint*

Specifies the number of the breakpoint to be cleared.

### \\*

Specifies that all breakpoints should be cleared.

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

To determine the breakpoint number of a breakpoint, use the **!amli bl** extension.

[Send comments about this topic to Microsoft](#)

# !amli bd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli bd** extension temporarily disables an AML breakpoint.

## Syntax

```
!amli bd Breakpoint!amli bd *
```

## Parameters

### *Breakpoint*

Specifies the number of the breakpoint to be disabled.

\\*

Specifies that all breakpoints should be disabled.

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

A disabled breakpoint can be re-enabled by using the [!amli be](#) extension.

To determine the breakpoint number of a breakpoint, use the [!amli bl](#) extension.

Here is an example of this command:

```
kd> !amli bl
0: c29accf5 [_WAK]
1: c29c20a5 [_SB.PCI0.ISA.BAT1._BST]

kd> !amli bd 1
```

[Send comments about this topic to Microsoft](#)

# !amli be

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli be** extension enables an AML breakpoint.

## Syntax

```
!amli be Breakpoint!amli be *
```

## Parameters

### *Breakpoint*

Specifies the breakpoint number of the breakpoint to be enabled.

\\*

Specifies that all breakpoints should be enabled.

### **DLL**

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

All breakpoints are enabled when they are created. Breakpoints are only disabled if you have used the **!amli bd** extension.

To determine the breakpoint number of a breakpoint, use the **!amli bl** extension.

[Send comments about this topic to Microsoft](#)

# !amli bl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli bl** extension displays a list of all AML breakpoints.

## Syntax

```
!amli bl
```

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

The AMLI Debugger supports a maximum of ten breakpoints.

Here is an example of the **!amli bl** extension:

```
kd> !amli bl
0: <e> ffffffff80e5e2f1:[_SB.LNKD._SRS]
1: <e> ffffffff80e5d969:[_SB.LNKB._STA]
2: <d> ffffffff80e630c9:[_WAK]
3: <e> ffffffff80e612c9:[_SB.MBRD._CRS]
```

The first column gives the breakpoint number. The **<e>** and **<d>** marks indicate whether the breakpoint is enabled or disabled. The address of the breakpoint is in the next column. Finally, the method containing the breakpoint is listed, with the offset of the breakpoint if it is not set at the start of the method.

[Send comments about this topic to Microsoft](#)

# !amli bp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli bp** extension places a breakpoint in AML code.

## Syntax

```
!amli bp { MethodName | CodeAddress }
```

## Parameters

### *MethodName*

Specifies the full path of the method name on which the breakpoint will be set.

### *CodeAddress*

Specifies the address of the AML code at which the breakpoint will be set. If *CodeAddress* is prefixed with two percent signs (%%), it is interpreted as a physical address. Otherwise, it is interpreted as a virtual address.

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

The AMLI Debugger supports a maximum of 10 breakpoints.

Here is an example. The following command will set a breakpoint on the \_DCK method:

```
kd> !amli bp _sb.pci0.dock._dck
```

[Send comments about this topic to Microsoft](#)

# !amli cl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli cl** extension clears the AML interpreter's event log.

## Syntax

```
!amli cl
```

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

[Send comments about this topic to Microsoft](#)

# !amli debugger

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli debugger** extension breaks into the AMLI Debugger.

## Syntax

```
!amli debugger
```

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

When this command is issued, notification is sent to the AML interpreter. The next time the interpreter is active, it will immediately break into the AMLI Debugger.

The **!amli debugger** extension only causes one break. If you want it to break again, you need to use this extension again, or set a breakpoint.

[Send comments about this topic to Microsoft](#)

# !aml dh

5/31/2017 • 1 min to read • [Edit Online](#)

The **!aml dh** extension displays the AML interpreter's internal heap block.

## Syntax

```
!aml dh [HeapAddress]
```

## Parameters

### *HeapAddress*

Specifies the address of the heap block. If this is omitted, the global heap is displayed.

### **DLL**

Kdexts.dll

### **Additional Information**

For information about related commands and their uses, see [The AMLI Debugger](#).

[Send comments about this topic to Microsoft](#)

# !amli dl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli dl** extension displays a portion of the AML interpreter's event log.

## Syntax

```
!amli dl
```

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

The event log chronicles the most recent 150 events that occurred in the interpreter.

Here is an example of the log display:

```
kd> !amli dl
RUN!: [c15a6618]QTh=00000000,QCt=00000000,QFg=00000000: Ctx=c18b4000,rc=0
KICK: [c15a6618]QTh=00000000,QCt=00000000,QFg=00000000: rc=0
SYNC: [c15a6618]QTh=00000000,QCt=00000000,QFg=00000002,LockPhase=0,Locked=0,IRQL=00: Obj=_WAK
ASYN: [c15a6618]QTh=00000000,QCt=00000000,QFg=00000002,LockPhase=0,Locked=0,IRQL=00: Obj=_WAK
REST: [c15a6618]QTh=00000000,QCt=00000000,QFg=00000002: Ctx=c18b4000,Obj=_WAK
INSQ: [c15a6618]QTh=00000000,QCt=00000000,QFg=00000002: Ctx=c18b4000,Obj=_WAK
EVAL: [c15a6618]QTh=00000000,QCt=00000000,QFg=00000002: Ctx=c18b4000,Obj=_WAK
RUNC: [c15a6618]QTh=c15a6618,QCt=c18b4000,QFg=00000002: Ctx=c18b4000,Obj=_WAK
```

[Send comments about this topic to Microsoft](#)

# !amli dns

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli dns** extension displays an ACPI namespace object.

## Syntax

```
!amli dns [/s] [Name | Address]
```

## Parameters

### **/s**

Causes the entire namespace subtree under the specified object to be displayed recursively.

### *Name*

Specifies the namespace path.

### *Address*

Specifies the address of the namespace node.

### **DLL**

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

If neither *Name* nor *Address* is specified, the entire ACPI namespace tree is displayed recursively. The **/s** parameter is always assumed in this case, even if it is not specified.

This command is useful for determining what a particular namespace object is—whether it is a method, a field unit, a device, or another type of object.

Without the **/s** parameter, this extension is equivalent to the **!nsobj** extension. With the **/s** parameter, it is equivalent to the **!nstree** extension.

Here are some examples. The following command displays the namespace for the object **bios**:

```
AMLI(? for help)-> dns \bios

ACPI Name Space: \BIOS (80E5F378)
OpRegion(BIOS:RegionSpace=SystemMemory,Offset=0xfc07500,Len=2816)
```

The following command displays the namespace for the object **\_BST**, and the tree subordinate to it:

```
kd> !amli dns /s _sb.pci0.isa.bat1._bst

ACPI Name Space: _SB.PCI0.ISA.BAT1._BST (c29c2044)
Method(_BST:Flags=0x0,CodeBuff=c29c20a5,Len=103)
```

To display the namespace for the device **BAT1**, type:

```
kd> !aml1 dns /s _sb.pci0.isa.bat1
```

To display the namespace of everything subordinate to the DOCK device, type:

```
kd> !aml1 dns /s _sb.pci0.dock
```

To display the namespace subordinate to the \_DCK method, type:

```
kd> !aml1 dns /s _sb.pci0.dock._dck
```

To display the entire namespace, type:

```
kd> !aml1 dns
```

[Send comments about this topic to Microsoft](#)

# !amli do

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli do** extension displays an AML data object.

## Syntax

```
!amli do Address
```

## Parameters

### *Address*

Specifies the address of the data object.

### **DLL**

Kdexts.dll

### **Additional Information**

For information about related commands and their uses, see [The AMLI Debugger](#).

[Send comments about this topic to Microsoft](#)

# !amli ds

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli ds** extension displays an AML stack.

## Syntax

```
!amli ds [/v] [Address]
```

## Parameters

### /v

Causes the display to be verbose. In Windows 2000, this option is available only if you are using the checked build of this extension (w2kchk\Acpikd.dll).

### Address

Specifies the address of the context block whose stack is desired. If *Address* is omitted, the current context is used.

### DLL

The !stacks extension displays information about the kernel stacks.

### Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

[Send comments about this topic to Microsoft](#)

# !amli find

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli find** extension finds an ACPI namespace object.

## Syntax

```
!amli find Name
```

## Parameters

### Name

Specifies the name of the namespace object (without the path).

### DLL

Kdexts.dll

### Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

The **!amli find** command takes the name of the object and returns the full path and name. The *Name* parameter must be the final segment of the full path and name.

Here are some examples. The following command will find all declarations of the object `_SRS`:

```
kd> !amli find _srs
_SB.LNKA._SRS
_SB.LNKB._SRS
_SB.LNKC._SRS
_SB.LNKD._SRS
```

This is not simply a text search. The command **!amli find srs** does not display any hits, because the final segment of each of these declarations is `"_SRS"`, not `"SRS"`. The command **!amli find LNK** similarly does not return hits. The command **!amli find LNKB** would display the single node that terminates in `"LNKB"`, not the four children of this node shown in the previous display:

```
kd> !amli find lnkb
_SB.LNKB.
```

If you need to see the children of a node, use the **!amli dns** command with the `/s` parameter.

Here is another example, issued from the AMLI Debugger prompt. This shows all declarations of the object `_BST` in the namespace:

```
AMLI(?) for help)-> find _bst
_SB.PCI0.ISA.BAT1._BST
_SB.PCI0.ISA.BAT2._BST
```

[Send comments about this topic to Microsoft](#)

# !amli lc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli lc** extension lists all active ACPI contexts.

## Syntax

```
!amli lc
```

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

Each context corresponds to a method currently running in the AML interpreter.

Here is an example:

```
AMLI(? for help)-> lc
Ctxt=80e3f000, ThID=00000000, Flgs=A--C----, pb0p=00000000, Obj=_SB.LNKA._STA
Ctxt=80e41000, ThID=00000000, Flgs=A--C----, pb0p=00000000, Obj=_SB.LNKB._STA
Ctxt=80e9a000, ThID=00000000, Flgs=A--C----, pb0p=00000000, Obj=_SB.LNKC._STA
Ctxt=80ea8000, ThID=00000000, Flgs=A--C----, pb0p=00000000, Obj=_SB.LNKD._STA
*Ctxt=80e12000, ThID=80e6eda8, Flgs=---CR----, pb0p=80e5d5ac, Obj=_SB.LNKA._STA
```

The **Obj** field gives the full path and name of the method as it appears in the ACPI tables.

The **Ctxt** field gives the address of the context block. The asterisk (**\**) *indicates the \*current context*. This is the context that was being executed by the interpreter when the break occurred.

The abbreviation **pbOp** indicates the instruction pointer (pointer to binary op codes).

There are nine flags that can be displayed in the **Flgs** section. If a flag is not set, a hyphen is displayed instead. The full list of flags is as follows:

| FLAG | MEANING                 |
|------|-------------------------|
| A    | Asynchronous evaluation |
| N    | Nested evaluation       |
| Q    | In the ready queue      |
| C    | Needs a callback        |

| FLAG | MEANING        |
|------|----------------|
| R    | Running        |
| W    | Ready          |
| T    | Time-out       |
| D    | Timer dispatch |
| P    | Timer pending  |

[Send comments about this topic to Microsoft](#)

# !amli ln

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli ln** extension displays the specified method or the method containing a given address.

## Syntax

```
!amli ln [MethodName | CodeAddress]
```

## Parameters

### *MethodName*

Specifies the full path of the method name. If *MethodName* specifies an object that is not actually a method, an error results.

### *CodeAddress*

Specifies the address of the AML code that is contained in the desired method. If *CodeAddress* is prefixed with two percent signs (%%), it is interpreted as a physical address. Otherwise, it is interpreted as a virtual address.

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

If neither *MethodName* nor *CodeAddress* is specified, the method associated with the current context is displayed.

The following command shows the method being currently run:

```
kd> !amli ln
c29acccf5: _WAK
```

The method `_WAK` is shown, with address 0xC29ACCF5.

[Send comments about this topic to Microsoft](#)

# !amli r

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli r** extension displays information about the current context or the specified context.

## Syntax

```
!amli r [ContextAddress]
```

## Parameters

### *ContextAddress*

Specifies the address of the context block to be displayed. The address of a context block can be determined from the **Ctxt** field in the **!amli lc** display. If *ContextAddress* is prefixed with two percent signs (%%), it is interpreted as a physical address. Otherwise, it is interpreted as a virtual address. If this parameter is omitted, the current context is displayed.

### **DLL**

Kdexts.dll

### **Additional Information**

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

If the AMLI Debugger prompt appears suddenly, this is a useful command to use.

For example, the following command will display the current context of the interpreter:

```
AMLI(? for help)-> r

Context=c18b4000*, Queue=00000000, ResList=00000000
ThreadID=c15a6618, Flags=00000010
StackTop=c18b5eec, UsedStackSize=276 bytes, FreeStackSize=7636 bytes
LocalHeap=c18b40c0, CurrentHeap=c18b40c0, UsedHeapSize=88 bytes
Object=_WAK, Scope=_WAK, ObjectOwner=c18b4108, SyncLevel=0
AsyncCallBack=ff06b5d0, CallBackData=0, CallBackContext=c99efddc

MethodObject=_WAK
80e0ff5c: Local0=Unknown()
80e0ff70: Local1=Unknown()
80e0ff84: Local2=Unknown()
80e0ff98: Local3=Unknown()
80e0ffac: Local4=Unknown()
80e0ffc0: Local5=Unknown()
80e0ffd4: Local6=Unknown()
80e0ffe8: Local7=Unknown()
80e0e040: RetObj=Unknown()

Next AML Pointer: ffffffff80e630df:[_WAK+16]

fffffff80e630df : If(S4BW
fffffff80e630e5 : {
fffffff80e630e5 : | Store(Zero, S4BW
fffffff80e630eb : }
```

[Send comments about this topic to Microsoft](#)

# !amliset

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amliset** extension sets or displays the AMLI Debugger options.

```
!amliset Options
```

## Parameters

### *Options*

Specifies one or more options to be set. Separate multiple options with spaces. Possible values include:

#### **spewon**

Causes full debug output to be sent from the target computer. This option should be left on at all times for effective AML debugging. See the Remarks section for details.

#### **spewoff**

Suppresses debug output.

#### **verboseon**

Turns on verbose mode. This causes the AMLI Debugger to display the names of AML methods as they are evaluated.

#### **verboseoff**

Turns off verbose mode.

#### **traceon**

Activates ACPI tracing. This produces much more output than the **verboseon** option. This option is very useful for tracking SMI-related hard hangs.

#### **traceoff**

Deactivates ACPI tracing.

#### **nesttraceon**

Activates nest tracing. This option is only effective if the **traceon** option is also selected.

#### **dbgbrkon**

Enables breaking into the AMLI Debugger.

#### **dbgbrkoff**

Deactivates the dbgbrkon option.

#### **nesttraceoff**

Deactivates nest tracing.

#### **Ibrkon**

Breaks into the AMLI Debugger when DDB loading is completed.

#### **Ibrkoff**

Deactivates the **Ibrkon** option.

#### **errbrkon**

Breaks into the AMLI Debugger whenever the interpreter has a problem evaluating AML code.

**errbrkoff**

Deactivates the **errbrkon** option.

**logon**

Enables event logging.

**logoff**

Disables event logging.

**logmuton**

Enables mutex event logging.

**logmutoff**

Disables mutex event logging.

**DLL**

Kdexts.dll

**Additional Information**

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

If no options are specified, the current status of all options is displayed.

By default, many messages are filtered out, you may need to turn this output on with **!aml set spewon**. Otherwise, numerous AMLI Debugger messages will be lost.

If the AML interpreter breaks into the AMLI Debugger, this output will be automatically turned on.

For more details on this output filtering, see **DbgPrintEx** and **KdPrintEx** in the Windows Driver Kit (WDK) documentation.

[Send comments about this topic to Microsoft](#)

# !amli u

5/31/2017 • 1 min to read • [Edit Online](#)

The **!amli u** extension unassembles AML code.

## Syntax

```
!amli u [MethodName | CodeAddress]
```

## Parameters

### *MethodName*

Specifies the full path of the method name to be disassembled.

### *CodeAddress*

Specifies the address of the AML code where disassembly will begin. If *CodeAddress* is prefixed with two percent signs (%%), it is interpreted as a physical address. Otherwise, it is interpreted as a virtual address.

## DLL

Kdexts.dll

## Additional Information

For information about related commands and their uses, see [The AMLI Debugger](#).

## Remarks

If neither *MethodName* nor *CodeAddress* is specified and you are issuing this command from an AMLI

The disassembly display will continue until the end of the method is reached.

**Note** The standard **u (Unassemble)** command will not give proper results with AML code.

Here are some examples. To disassemble the object at address 0x80E5D701, use the following command:

```
kd> !amli u 80e5d701

ffffffff80e5d701 : CreateWordField(CRES, 0x1, IRQW)
ffffffff80e5d70c : And(_SB_.PCI0.LPC_.PIRA, 0xf, Local0)
ffffffff80e5d723 : Store(One, Local1)
ffffffff80e5d726 : ShiftLeft(Local1, Local0, IRQW)
ffffffff80e5d72d : Return(CRES)
```

The following command will disassemble the \_DCK method:

```
kd> u _sb.pci0.dock._dck
```

# !fac

5/31/2017 • 1 min to read • [Edit Online](#)

The **!fac** extension displays a Firmware ACPI Control Structure (FACS).

## Syntax

```
!fac Address
```

## Parameters

### *Address*

Specifies the address of the FACS.

### **DLL**

Kdexts.dll

### **Additional Information**

For more information, see [ACPI Debugging](#).

[Send comments about this topic to Microsoft](#)

# !fadt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!fadt** extension displays a Fixed ACPI Description Table (FADT).

## Syntax

```
!fadt Address
```

## Parameters

### *Address*

Specifies the address of the FADT.

### **DLL**

Kdexts.dll

### **Additional Information**

For more information, see [ACPI Debugging](#).

[Send comments about this topic to Microsoft](#)

# !mapic

5/31/2017 • 1 min to read • [Edit Online](#)

The **!mapic** extension displays an ACPI Multiple APIC table.

## Syntax

```
!mapic Address
```

## Parameters

### *Address*

Specifies the address of the Multiple APIC Table.

### **DLL**

Kdexts.dll

### **Additional Information**

For more information, see [ACPI Debugging](#).

[Send comments about this topic to Microsoft](#)

# !nsobj

5/31/2017 • 1 min to read • [Edit Online](#)

The **!nsobj** extension displays an ACPI namespace object.

## Syntax

```
!nsobj [Address]
```

## Parameters

### *Address*

Specifies the address of the namespace object. If this is omitted, the root of the namespace tree is used.

### **DLL**

Kdexts.dll

### **Additional Information**

For more information, see [ACPI Debugging](#).

## Remarks

This extension is equivalent to [!amli dns](#).

[Send comments about this topic to Microsoft](#)

# !nstree

5/31/2017 • 1 min to read • [Edit Online](#)

The **!nstree** extension displays an ACPI namespace object and its children in the namespace tree.

## Syntax

```
!nstree [Address]
```

## Parameters

### *Address*

Specifies the address of the namespace object. This object and the entire namespace tree subordinate to it will be displayed. If *Address* is omitted, the entire namespace tree is displayed.

### **DLL**

Kdexts.dll

### **Additional Information**

For more information, see [ACPI Debugging](#).

## Remarks

This extension is equivalent to [!amli dns /s](#).

[Send comments about this topic to Microsoft](#)

# !rsdt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rsdt** extension displays the ACPI Root System Description Table.

## Syntax

```
!rsdt
```

## DLL

Kdexts.dll

## Additional Information

For more information, see [ACPI Debugging](#).

[Send comments about this topic to Microsoft](#)

# Graphics Driver Extensions (Gdikdx.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands that are useful for debugging the Graphics Driver Interface (GDI) can be found in Gdikdx.dll.

The Windows 2000 version of this extension DLL appears in the w2kfre and w2kchk directories. There is no version of this DLL for Windows XP or later versions of Windows.

[Send comments about this topic to Microsoft](#)

# !gdikdx.verifier

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gdikdx.verifier** extension displays the status of Driver Verifier during the verification of a graphics driver.

```
!gdikdx.verifier [-Flags]
```

## Parameters

### *Flags*

Specifies what information will be displayed in the output from this command. Any combination of the following (preceded by a hyphen) is allowed:

**d**

Causes the display to include statistics on **Memory Pool Tracking**. This includes the address, size, and tag of each pool.

**h (or ?)**

Displays some brief Help text for this command in the Debugger Command window.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Gdikdx.dll  |
| <b>Windows XP and later</b> | Unavailable |

## Additional Information

For information about Driver Verifier, see the Windows Driver Kit (WDK) documentation.

## Remarks

When verifying drivers that are not graphics drivers, the standard kernel-mode extension **IVerifier** should be used instead of **!gdikdx.verifier**.

Regardless of which flags are selected, this extension will display the Driver Verifier options that are active. It will also display statistics on the frequency of random failure.

[Send comments about this topic to Microsoft](#)

# Kernel Streaming Extensions (Ks.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands that are useful for debugging kernel streaming drivers and AVStream drivers can be found in Ks.dll.

Most of the sample output in these reference pages was generated by debugging the filter-centric sample Avssamp.sys. This sample is included in the Windows Driver Kit.

If you wish to use the Ks.dll extensions with Windows 2000, you must copy Ks.dll from the kdexts directory to the w2kfre directory.

You need special symbols to use this extension. For more information, see the [Debugging Tools for Windows](#) Web site.

You can get additional information for many of the extension commands in this section simply by entering the command into the debugger with no arguments.

For more information, see [Kernel Streaming Debugging](#).

[Send comments about this topic to Microsoft](#)

# !ks.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.help** extension displays a help text showing all AVStream-specific Ks.dll extension commands.

```
!ks.help
```

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

[Send comments about this topic to Microsoft](#)

# !ks.kshelp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.kshelp** extension displays a help text showing original KS 1.0-specific Ks.dll extension commands.

```
!ks.kshelp
```

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |

# !ks.pchelp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.pchelp** extension displays a help text showing PortCls-specific Ks.dll extension commands.

```
!ks.pchelp
```

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

[Send comments about this topic to Microsoft](#)

# !ks.allstreams

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.allstreams** extension walks the entire device tree and finds every kernel streaming device in the system.

```
!ks.allstreams [Flags] [Level]
```

## Parameters

### *Flags*

Optional. Specifies the kind of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x1:

Bit 0 (0x1)

Causes the display to include streams.

Bit 2 (0x4)

Causes the display to include proxy instances.

Bit 3 (0x8)

Causes the display to include queued IRPs.

Bit 4 (0x10)

Causes the display to include an unformatted display of all streams.

Bit 5 (0x20)

Causes the display to include an unformatted display of all stream formats.

### *Level*

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

This command can take some time to execute (a minute is not unusual).

Here is an example of the **!ks.allstreams** display:

```
kd> !allstreams
6 Kernel Streaming FDOs found:
 Functional Device 82a17690 [\Driver\smwdm]
 Functional Device 8296eb08 [\Driver\wdmaud]
 Functional Device 82490388 [\Driver\sysaudio]
 Functional Device 82970cb8 [\Driver\MSMQM]
 Functional Device 824661b8 [\Driver\MSPCLOCK]
 Functional Device 8241c020 [\Driver\avssamp]
```

[Send comments about this topic to Microsoft](#)

# !ks.automation

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ks.automation** extension displays any automation items associated with the given object.

`!ks.automation` Object

## Parameters

### Object

Specifies a pointer to the object for which to display automation items. (Automation items are properties, methods, and events.) *Object* must be one of the following types: PKSPIN, PKSFILTER, CKsPin\*, CKsFilter\*, PIRP. If *Object* is a pointer to an automation IRP, the command returns property information and handlers.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

You can use this command with a filter address obtained from [!ks.enumdevobj](#).

Here is an example of the **!ks.automation** display. The argument is the address of a filter:

```
kd> !automation 829493c4
Filter 829493c4 has the following automation items:
Property Items:
 Set KSPROPSETID_Pin
 Item ID = KSPROPERTY_PIN_CINSTANCES
 Get Handler = ks!CKsFilter::Property_Pin
 Set Handler = NULL

# !ks.devhdr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.devhdr** extension displays the kernel streaming device header associated with the given WDM object.

```
!ks.devhdr DeviceObject
```

## Parameters

### *DeviceObject*

This parameter specifies a pointer to a WDM device object. If *DeviceObject* is not valid, the command returns an error.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

The output from **!ks.allstreams** can be used as the input for **!ks.devhdr**.

Here is an example of the **!ks.devhdr** display:

```
kd> !devhdr 827aedf0 7
Device Header 824ca1e0
 Child Create Handler List:
 Create Item eb3a7284
 CreateFunction = sysaudio!CFilterInstance::FilterDispatchCreate+0x00
 ObjectClass = NULL
 Flags = 0
```

[Send comments about this topic to Microsoft](#)

# !ks.dhdr

5/26/2017 • 1 min to read • [Edit Online](#)

The **!ks.dhdr** extension command is obsolete; use **!ks.dump** instead.

[Send comments about this topic to Microsoft](#)

# !ks.dump

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ks.dump** extension displays the specified object.

```
!ks.dump Object [Level] [Flags]
```

## Parameters

### *Object*

Specifies a pointer to an AVStream structure, an AVStream class object, or a PortCls object. Can also specify a pointer to an an IRP or a file object.

### *Level*

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7. You can see more information about levels by issuing a **!ks.dump** command with no arguments.

### *Flags*

Optional. Specifies the kind of information to be displayed. *Flags* can be any combination of the following bits.

Bit 0 (0x1)

Display all queued IRPs.

Bit 1 (0x2)

Display all pending IRPs.

Bit 2 (0x4)

Analyze a stalled graph for suspects.

Bit 3 (0x8)

Show all pin states.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

The **!ks.dump** command recognizes most AVStream objects, including pins, filters, factories, devices, pipes, and stream pointers. This command also recognizes some stream class structures, including stream objects, filter instances, device extensions, and SRBs.

Following is an example of the **!ks.dump** display for a filter:

```

kd> !dump 829493c4
Filter object 829493c4 [CKsFilter = 82949350]
 Descriptor f7a233c8:
 Context 829dce28

```

Following is an example of the **!ks.dump** display for a pin:

```

kd> !dump 8160DDE0 7
Pin object 8160DDE0 [CKsPin = 8160DD50]
 DeviceState KSSTATE_RUN
 ClientState KSSTATE_RUN
 ResetState KSRESET_END
 CKsPin object 8160DD50 [KSPIN = 8160DDE0]
 State KSSTATE_RUN
 Processing Mutex 8160DFD0 is not held
 And Gate & 8160DF88
 And Gate Count 1

```

Some important parts of this display are included in the following table.

| Parameter   | Meaning                                                                                                                                      |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| DeviceState | The state that the pin was requested to enter. If different from ClientState, this is the state that the minidriver will transition to next. |
| ClientState | The state that the minidriver is actually in. This reflects the state of the pipe.                                                           |
| ResetState  | Indicates whether or not the object is in the middle of a flush.<br>KSRESET_BEGIN indicates a flush.<br>KSRESET_END indicates no flush.      |
| State       | The internal state of the pin's transport to non-AVStream filters.                                                                           |

Following is an example of the **!ks.dump** display for a stream class driver:

```

kd> !dump 81a0a170 7
Device Extension 81a0a228:
 Device Object 81a0a170 [\Driver\TESTCAP]
 Next Device Object 81bd56d8 [\Driver\PnpManager]
 Physical Device Object 81bd56d8 [\Driver\PnpManager]
REGISTRY FLAGS:
 Page out driver when closed
 No suspend if running
MINIDRIVER Data:
 Device Extension 81a0a44c
 Interrupt Routine 00000000
 Synchronize Routine STREAM!StreamClassSynchronizeExecution
 Receive Device SRB testcap!AdapterReceivePacket
 Cancel Packet testcap!AdapterCancelPacket
 Timeout Packet testcap!AdapterTimeoutPacket
 Size (d / r / s / f) 1a0(416), 14(20), 978(2424), 0(0)
 Sync Mode Driver Synchronizes
Filter Type 0:
 Symbolic Links:
 Information Paged Out
 Instances:
 816b7bd8

```

Note that the sizes are listed both in hexadecimal numbers, and then, parenthetically in the decimal equivalent. The Size abbreviations in this display are listed in the following table.

| Size | Explanation                                                                                                    |
|------|----------------------------------------------------------------------------------------------------------------|
| d    | Device                                                                                                         |
| r    | Request                                                                                                        |
| s    | Stream                                                                                                         |
| f    | Filter. If the filter size is 0, the filter is single instance. If it is greater than 0, it is multi-instance. |

[Send comments about this topic to Microsoft](#)

# !ks.dumpbag

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.dumpbag** extension displays the contents of the object bag for the specified object.

```
!ks.dumpbag Object [Level]
```

## Parameters

### *Object*

Specifies a pointer to a valid client viewable object structure, or to the private class object.

### *Level*

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

Here is an example of the **!ks.dumpbag** display for a filter:

```
kd> !dumpbag 829493c4
Filter 829493c4 [CKsFilter = 82949350]:
Object Bag 829493d0:
Object Bag Item 829dce28:
 Reference Count : 1
 Item Cleanup Handler : f7a21730
```

[Send comments about this topic to Microsoft](#)

# !ks.dumpcircuit

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.dumpcircuit** extension lists details of the transport circuit associated with the given object.

```
!ks.dumpcircuit extension Object [Level]
```

## Parameters

### Object

Specifies a pointer to the object for which to display the transport circuit. For AVStream, *Object* must be one of the following types: CKsPin\*, CKsQueue\*, CKsRequestor\*, CKsSplitter\*, CKsSplitterBranch\*.

For PortClIs, object must be one of the following types: CPortPin\*, CKsShellRequestor\*, or ClrpStream\*.

### Level

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

Note that **!ks.dumpcircuit** starts walking the circuit at the specified object, which does not always correspond to the data source.

You can first use **!ks.graph** with a filter address to list pin addresses, and then use these addresses with **!ks.dumpcircuit**.

Here is an example of the **!ks.dumpcircuit** display:

```
kd> !dumpcircuit 8293f4f0
Pin8293f4f0 0 (snk, out)
Queue82990e20 r/w/c=2489/2/0
```

[Send comments about this topic to Microsoft](#)

# !ks.dumplog

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.dumplog** extension displays the internal kernel streaming debug log.

```
!ks.dumplog [Entries]
```

## Parameters

### *Entries*

Optional. Specifies the number of log entries to display. If *Entries* is zero or omitted, the entire log is displayed.

### DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

### Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

You can stop the log display by pressing **CTRL+C**.

This extension requires that the target computer be running a checked (debug) version of Ks.sys.

[Send comments about this topic to Microsoft](#)

# !ks.dumpqueue

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.dumpqueue** extension displays information about the queues associated with a given AVStream object, or the stream associated with a port class object.

```
!ks.dumpqueue Object [Level]
```

## Parameters

### *Object*

Specifies a pointer to the object for which to display the queue. *Object* must be of type PKSPIN, PKSFILTER, CKsPin\*, CKsFilter\*, CKsQueue\*, CPortPin\*, or CPortFilter\*.

### *Level*

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

*Object* must be a filter or a pin. For a pin, a single queue is displayed. For a filter, multiple queues are displayed.

This command can take some time to execute.

Here is an example of the **!ks.dumpqueue** display:

```
kd> !dumpqueue 829493c4
Filter 829493c4: Output Queue 82990e20:
Queue 82990e20:
 Frames Received : 1889
 Frames Waiting : 3
 Frames Cancelled: 0
 And Gate 82949464 : count = 1, next = 00000000
 Frame Gate NULL
 Frame Header 82aaef78:
 NextFrameHeaderInIrp = 00000000
 OriginalIrp = 82169e48
 Mdl = 8292e358
 Irp = 82169e48
 StreamHeader = 8298dea0
 FrameBuffer = edba3000
 StreamHeaderSize = 00000000
 FrameBufferSize = 00025800
 Context = 00000000
 Refcount = 1
```

[Send comments about this topic to Microsoft](#)

# !ks.enumdevobj

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.enumdevobj** extension displays the KSDEVICE associated with a given WDM device object, and lists the filter types and filters currently instantiated on this device.

```
!ks.enumdevobj DeviceObject
```

## Parameters

### *DeviceObject*

Specifies a pointer to a WDM device object.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

The output from [!ks.allstreams](#) can be used as the input for **!ks.enumdevobj**.

Here is an example of the **!ks.enumdevobj** display:

```
kd> !enumdevobj 8241c020
WDM device object 8241c020:
 Corresponding KSDEVICE 823b8430
 Factory 829782dc [Descriptor f7a233c8] instances:
 829493c4
```

[Send comments about this topic to Microsoft](#)

# !ks.enumdrvobj

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.enumdrvobj** extension displays all KSDEVICE structures associated with a given WDM driver object, and lists the filter types and filters currently instantiated on these devices.

```
!ks.enumdrvobj DriverObject
```

## Parameters

### *DriverObject*

Specifies a pointer to a WDM driver object.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

Since **!ks.enumdrvobj** enumerates every device chained off a WDM driver object, it is equivalent to invoking **!ks.enumdevobj** on every device chained off a given driver.

[Send comments about this topic to Microsoft](#)

# !ks.eval

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.eval** extension evaluates an expression using an extension-specific expression evaluator.

```
!ks.eval Expression
```

## Parameters

### *Expression*

Specifies the expression to evaluate. *Expression* can include any MASM operators, symbols, or numerical syntax, as well as the extension-specific operators described below. For more information about MASM expressions, see [MASM Numbers and Operators](#).

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

The extension module includes two extension-specific operators which can be used in address parameters to extension commands:

### **fdo( x )**

Returns the functional device object associated with the object at address **x**.

### **driver( x )**

Returns the driver object associated with **fdo(x)**.

You can use the **!ks.eval** command to parse expressions that contain these extension-specific operators as well as [MASM Numbers and Operators](#).

Note that all operators supported by **!ks.eval** are also supported by all other extension commands in the Ks.dll extension module.

Here is an example of the **!ks.eval** extension being used with the address of a filter. Note the presence of the 0x8241C020 address in the **!ks.allstreams** output:

```
kd> !eval fdo(829493c4)
Resulting Evaluation: 8241c020

kd> !allstreams
6 Kernel Streaming FDOs found:
 Functional Device 82a17690 [\Driver\smwdm]
 Functional Device 8296eb08 [\Driver\wdmaud]
 Functional Device 82490388 [\Driver\sysaudio]
 Functional Device 82970cb8 [\Driver\MSPCM]
 Functional Device 824661b8 [\Driver\MSPCLOCK]
 Functional Device 8241c020 [\Driver\avssamp]
```

[Send comments about this topic to Microsoft](#)

# !ks.findlive

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.findlive** extension searches the internal Ks.sys debug log to attempt to find live objects of a specified type.

```
!ks.findlive Type [Entries] [Level]
```

## Parameters

### Type

Specifies the type of object for which to search. Enter one of the following as a literal value: **Queue**, **Requestor**, **Pin**, **Filter**, or **Irp**.

### Entries

If this parameter is zero or omitted, the entire log is searched.

### Level

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

The **!ks.findlive** command may not find all possible specified live objects.

This extension requires that the target computer be running a checked (debug) version of Ks.sys.

[Send comments about this topic to Microsoft](#)

# !ks.forcedump

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ks.forcedump** command displays information about memory contents at a caller-supplied address.

```
!ks.forcedump Object Type [Level]
```

## Parameters

### *Object*

Specifies a pointer to the object for which to display information.

### *Type*

Specifies the type of object.

For AVStream/KS objects, *Type* must be one of the following values: CKsQueue, CKsDevice, CKsFilterFactory, CKsFilter, CKsPin, CKsRequestor, CKsSplitter, CKsSplitterBranch, CKsPipeSection, KSPIN, KSFILTER, KSFILTERFACTORY, KSDEVICE, KSSTREAM\_POINTER, KSPFRAME\_HEADER, KSIOBJECT\_HEADER, KSPDO\_EXTENSION, KSIDevice\_HEADER, KSSTREAM\_HEADER, KSPIN\_DESCRIPTOR\_EX, CKsProxy, CKsInputPin, CKsOutputPin, CasyncItemHandler.

For Port Class objects, *Type* must be one of the following values: DEVICE\_CONTEXT, CPortWaveCyclic, CPortPinWaveCyclic, CPortTopology, CPortDMus, ClrpStream, CKsShellRequestor, CPortFilterWaveCyclic, CDmaChannel, CPortWavePci, CportPinWavePci.

### *Level*

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

Normally, you can use **!ks.dump** to display data structures.

However, if symbols are loaded incorrectly or too much information is paged out, the type identification logic in the **!ks.dump** command may fail to identify the type of structure at a given address.

If this happens, try using the **!ks.forcedump** command. This command works just like **!ks.dump** except that the user specifies the type of the object.

**Note** The **!ks.forcedump** command does not verify that *Type* is the correct type of structure found at the address provided in *Object*. The command assumes that this is the type of structure found at *Object* and displays data

accordingly.

A listing of all supported objects can be retrieved by issuing a **!ks.forcedump** command with no arguments.

Here are two examples of the output from **!ks.forcedump**, using the address of a filter for the *Object* argument but with different levels of detail:

```
kd> !forcedump 829493c4 KSFILTER
WARNING: I am dumping 829493c4 as a KSFILTER.
 No checking has been performed to ensure that it is this type!!!

Filter object 829493c4 [CKsFilter = 82949350]

[Send comments about this topic to Microsoft](#)

# !ks.graph

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.graph** extension command displays a textual description of the kernel mode graph in topologically sorted order.

```
!ks.graph Object [Level] [Flags]
```

## Parameters

### *Object*

Specifies a pointer to the object to use as a starting point for the graph. Must be a pointer to one of the following: file object, IRP, pin, or filter.

### *Level*

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7. The levels for **!ks.graph** are the same as those for [!ks.dump](#).

### *Flags*

Optional. Specifies the kind of information to be displayed. *Flags* can be any combination of the following bits.

Bit 0 (0x1)

Display a list of IRPs queued to each pin instance in the graph.

Bit 1 (0x2)

Display a list of IRPs that are pending from each pin instance in the graph. Only IRPs that the pin knows it is waiting for are displayed.

Bit 4 (0x10)

Analyze a stalled graph for suspect filters.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

This command may take a bit of time to process.

Issue a **!ks.graph** command with no arguments for help.

Here is an example of the **!ks.graph** display, with the address of a filter object:

```
kd> !graph 829493c4
Attempting a graph build on 829493c4... Please be patient...

Graph With Starting Point 829493c4:

"avssamp" Filter 82949350, Child Factories 1
 Output Factory 0 [Video/General Capture]:
 Pin 8293f4f0 (File 82503498) Irps(q/p) = 2, 0
```

[Send comments about this topic to Microsoft](#)

# !ks.libexts

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.libexts** extension provides access to Microsoft-supplied library extensions that are statically linked to the extension module.

```
!ks.libexts [Command] [Libext]
```

## Parameters

### *Command*

Optional. Specifies one of the following values. If this argument is omitted, **!ks.libexts** returns help information.

#### **disableall**

Disable all library extensions. When this is used, omit the *Libext* parameter.

#### **disable**

Disable a specific library extension by name. When this is used, specify the name in the *Libext* parameter.

#### **enableall**

Enable all library extensions. Only loaded components with correct symbols are enabled. When this is used, omit the *Libext* parameter.

#### **enable**

Enable a specific library extension by name. When this is used, specify the name in the *Libext* parameter. Only loaded components with correct symbols can be enabled.

#### **details**

Show details about all currently linked library extensions. When this is used, omit the *Libext* parameter.

### *Libext*

Specifies the name of a library extension. Required only for *Command* values of **enable** or **disable**.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

The extension module contains an extensibility framework that allows separate components to be built and linked into Ks.dll. These extra components are called library extensions.

The **!ks.libexts** command allows viewing of statistics about those library extensions as well as control over them. For details, issue **!ks.libexts** with no arguments.

[Send comments about this topic to Microsoft](#)

# !ks.objhdr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.objhdr** extension displays the kernel streaming object header associated with the specified file object.

```
!ks.objhdr FileObject [Level] [Flags]
```

## Parameters

### *FileObject*

This parameter specifies a pointer to a WDM file object. If *FileObject* is not valid, the command returns an error.

### *Level*

Optional. Values are the same as those for [!ks.dump](#).

### *Flags*

Optional. Values are the same as those for [!ks.dump](#).

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

Levels and flags for **!ks.objhdr** are identical to those described in [!ks.dump](#).

The output from [!ks.allstreams](#) and [!ks.enumdevobj](#) can be used as the input for **!ks.objhdr**. To do this with the *avssamp* sample, for instance, issue the following commands:

```
kd> !ks.allstreams
6 Kernel Streaming FDOs found:
 Functional Device 8299be18 [\Driver\smwdm]
 Functional Device 827c86d8 [\Driver\wdmaud]
 Functional Device 827c0f08 [\Driver\sysaudio]
 Functional Device 82424590 [\Driver\avssamp]
 Functional Device 82423720 [\Driver\MSMQ]
 Functional Device 82b91a88 [\Driver\MSPCLOCK]
kd> !ks.enumdevobj 82424590
WDM device object 82424590:
 Corresponding KSDEVICE 82427540
 Factory 8285baa4 [Descriptor f7a333c8] instances:
 82837a34
kd> !ks.objhdr 82837a34 7
```

The results of this command might be lengthy. Issue a Ctrl-BREAK (WinDbg) or Ctrl-C (NTSD, CDB, KD) to stop the output.

Here's a separate example:

```
kd> !ks.objhdr 81D828B8 7
Adjusting file object 81D828B8 to object header 81BC1008

Object Header 81BC1008
 Associated Create Items:
 Create Item F9F77E98
 CreateFunction = ks!CKsFilter::DispatchCreatePin+0x00
 ObjectClass = {146F1A80-4791-11D0-A5D6-28DB04C10000}
 Flags = 0
 Child Create Handler List:
 Create Item F9F85AA0
 CreateFunction = ks!CKsPin::DispatchCreateAllocator+0x00

 FastWrite = ks!KsDispatchFastReadFailure+0x00
 TargetState: KSTARGET_STATE_ENABLED
 TargetDevice: 00000000
 BaseDevice : 81BBDF10
 Stack Depth : 1
 Corresponding AVStream object = 81A971B0
```

[Send comments about this topic to Microsoft](#)

# !ks.ohdr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.ohdr** extension displays details of a kernel streaming object header.

```
!ks.ohdr Object [Level] [Flags]
```

## Parameters

### *Object*

This parameter specifies a pointer to a KS object header. If *Object* is not valid, the command returns an error.

### *Level*

Optional. Values are the same as those for [!ks.dump](#).

### *Flags*

Optional. Values are the same as those for [!ks.dump](#).

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

The **!ks.ohdr** command works similarly to [!ks.objhdr](#) in that it displays details of a KS object header. The difference is that the caller provides the direct address of the KS object header, instead of the address of the associated file object.

Levels and flags for **!ks.ohdr** are identical to those described in [!ks.dump](#).

If the data you are querying is not paged out, consider using [!ks.dump](#) instead of **!ks.ohdr**.

[Send comments about this topic to Microsoft](#)

# !ks.pciaudio

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.pciaudio** extension displays a list of FDOs currently attached to PortCls.

```
!ks.pciaudio [Options] [Level]
```

## Parameters

### Options

Optional. Specifies the kind of information to be displayed. *Options* can be any combination of the following bits.

Bit 0 (0x1)

Display a list of running streams.

Bit 1 (0x2)

Display a list all streams.

Bit 3 (0x4)

Output displayed streams. *Level* has meaning only when this bit is set.

### Level

Optional, and applicable only if Bit 3 is set in *Options*. Levels are the same as those for [!ks.dump](#).

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

Here is an example of the output from **!ks.pciaudio**:

```
kd> !ks.pciaudio
1 Audio FDOs found:
 Functional Device 8299be18 [\Driver\smwdm]
```

[Send comments about this topic to Microsoft](#)

# !ks.pciks

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.pciks** extension lists functional devices for kernel streaming devices that are attached to the PCI bus. Optionally, it can display information about active streams on those functional devices.

```
!ks.pciks [Flags] [Level]
```

## Parameters

### Flags

Optional. Specifies the kind of information to be displayed. *Flags* can be any combination of the following bits.

Bit 0 (0x1)

List all currently running streams.

Bit 1 (0x2)

Recurse graphs to find non-PCI devices.

Bit 2 (0x4)

Display a list of proxy instances.

Bit 3 (0x8)

Display currently queued Irps.

Bit 4 (0x10)

Display information about all streams.

Bit 5 (0x20)

Display active stream formats.

### Level

Optional, and applicable only to flag combinations that cause data to be displayed. Levels are the same as those for

[!ks.dump](#).

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

This command may take time to execute, especially if the ACPI filter driver is loaded, or if Driver Verifier is enabled and driver names are paged out.

Here is an example of the **!ks.pciks** display:

```
kd> !pciks
1 Kernel Streaming FDOs found:
 Functional Device 82a17690 [\Driver\smwdm]
```

[Send comments about this topic to Microsoft](#)

# !ks.shdr

5/26/2017 • 1 min to read • [Edit Online](#)

The **!ks.shdr** extension command is obsolete; use [!ks.dump](#) instead.

[Send comments about this topic to Microsoft](#)

# !ks.topology

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ks.topology** extension displays a sorted graph of the internal topology of the filter closest to *Object*.

```
!ks.topology Object [Level] [Flags]
```

## Parameters

### *Object*

Specifies a pointer to the object to use as a base for the graph. Can be a pointer to a file object, IRP, pin, filter, or other KS object.

### *Level*

Optional. Specifies the level of detail to display on a 0-7 scale with progressively more information displayed for higher values. To display all available details, supply a value of 7.

### *Flags*

Not currently available.

## DLL

|                             |              |
|-----------------------------|--------------|
| <b>Windows 2000</b>         | winxp\Ks.dll |
| <b>Windows XP and later</b> | Ks.dll       |

## Additional Information

For more information, see [Kernel Streaming Debugging](#).

## Remarks

For help, issue a **!ks.topology** command with no arguments.

Note that this command may take a few moments to execute.

[Send comments about this topic to Microsoft](#)

# SCSI Miniport Extensions (Scsikd.dll and Minipkd.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands that are useful for debugging SCSI miniport drivers can be found in Scsikd.dll and Minipkd.dll.

You can use the Scsikd.dll extension commands with any version of Windows. However, you can only use the Minipkd.dll extension commands with Windows XP and later versions of Windows. Commands in Minipkd.dll are only applicable to SCSIport-based miniports.

For more information, see [SCSI Miniport Debugging](#).

[Send comments about this topic to Microsoft](#)

# !scsikd.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!scsikd.help** extension displays help text for Scsikd.dll extension commands.

```
!scsikd.help
```

## DLL

|                             |            |

| <b>Windows 2000</b>         | Scsikd.dll |
| <b>Windows XP and later</b> | Scsikd.dll |

## Additional Information

For more information, see [SCSI Miniport Debugging](#).

[Send comments about this topic to Microsoft](#)

# !scsikd.classext

5/31/2017 • 1 min to read • [Edit Online](#)

The **!scsikd.classext** extension displays the specified class Plug and Play (PnP) device.

```
!scsikd.classext [Device [Level]]
```

## Parameters

### Device

Specifies the device object or device extension of a class PnP device. If *Device* is omitted, a list of all class PnP extensions is displayed.

### Level

Specifies the amount of detail to display. This parameter can take 0, 1, or 2 as values, with 2 giving the most detail. The default is 0.

## DLL

|                             |            |
|-----------------------------|------------|
| <b>Windows 2000</b>         | Scsikd.dll |
| <b>Windows XP and later</b> | Scsikd.dll |

## Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

Here is an example of the **!scsikd.classext** display:

```
0: kd> !scsikd.classext
' !scsikd.classext 8633e3f0 ' () "IBM" " / "DDYS-T09170M" " / "S93E" / "

# !scsikd.srbdata

5/31/2017 • 1 min to read • [Edit Online](#)

The **!scsikd.srbdata** extension displays the specified SRB\_DATA tracking block.

```
!scsikd.srbdata Address
```

## Parameters

### *Address*

Specifies the address of an SRB\_DATA tracking block.

### DLL

|                             |            |
|-----------------------------|------------|
| <b>Windows 2000</b>         | Scsikd.dll |
| <b>Windows XP and later</b> | Scsikd.dll |

### Additional Information

For more information, see [SCSI Miniport Debugging](#).

[Send comments about this topic to Microsoft](#)

# !minipkd.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.help** extension displays help text for the Minipkd.dll extension commands.

```
!minipkd.help
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

## Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

If an error message similar to the following appears, it indicates that the symbol path is incorrect and does not point to the correct version of the Scsiport.sys symbols.

```
minipkd error (0) <path> ... \minipkd\minipkd.c @ line 435
```

Use the [.sympath \(Set Symbol Path\)](#) command to display the current path and change the path. Use the [.reload \(Reload Module\)](#) command to reload symbols from the current path.

[Send comments about this topic to Microsoft](#)

# !minipkd.adapter

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.adapter** extension displays information about the specified adapter.

`!minipkd.adapter Address`

## Parameters

### *Address*

Specifies the address of an adapter.

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

### Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

The address of an adapter can be found in the **DevExt** field of the **!minipkd.adapters** display.

[Send comments about this topic to Microsoft](#)

# !minipkd.adapters

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.adapters** extension displays all of the adapters that work with the SCSI Port driver that have been identified in the system, and the individual devices associated with each adapter.

```
!minipkd.adapters
```

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

## Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

The display includes the driver name, the device object address, and the device extension address for each adapter. The display for each adapter also includes a list of each device on the adapter. The display for each device includes the device extension address, the SCSI address, the device object address, and some flags for the device. Information about the Plug and Play state and the power state is also included.

The flags in the display are explained in the following table:

| FLAG | MEANING                                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------------------|
| c    | Claimed. Indicates that the device has a driver on it.                                                                                   |
| m    | Missing. Indicates that the device was present on the bus in a prior scan but was not present during the latest scan.                    |
| e    | Enumerated. Indicates that the device has been reported to the Plug and Play manager.                                                    |
| v    | Visible. Indicates that the device has been enumerated by the system. This flag is more significant when it is not present for a device. |
| p    | Paging. Indicates that the device is in the paging path.                                                                                 |
| d    | Dump. Indicates that the device is in the crash dump path and will be used for a crash dump.                                             |

| FLAG | MEANING                                              |
|------|------------------------------------------------------|
| h    | Hibernate. Indicates that the device is hibernating. |

Here is an example of the **!minipkd.adapters** display:

```
0: kd> !minipkd.adapters
Adapter \Driver\lp6nds35 DO 86334a70 DevExt 86334b28
Adapter \Driver\adpu160m DO 8633da70 DevExt 8633db28
LUN 862e60f8 @(0,0,0) c ev pnp(00/ff) pow(0,0) DevObj 862e6040
LUN 863530f8 @(0,1,0) c ev p d pnp(00/ff) pow(0,0) DevObj 86353040
LUN 862e50f8 @(0,2,0) c ev pnp(00/ff) pow(0,0) DevObj 862e5040
LUN 863520f8 @(0,6,0) ev pnp(00/ff) pow(0,0) DevObj 86352040
Adapter \Driver\adpu160m DO 86376040 DevExt 863760f8
```

An error message similar to the following indicates that either the symbol path is incorrect and does not point to the correct version of the `Scsiport.sys` symbols, or that Windows has not identified any adapters that work with the SCSI Port driver.

```
minipkd error (0) <path> ... \minipkd\minipkd.c @ line 435
```

If the **!minipkd.help** extension command returns help information successfully, the SCSI Port symbols are correct.

[Send comments about this topic to Microsoft](#)

# !minipkd.exports

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.exports** extension displays the addresses of the miniport exports for the specified adapter.

```
!minipkd.exports Adapter
```

## Parameters

### *Adapter*

Specifies the address of an adapter.

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

### Additional Information

For more information, see [SCSI Miniport Debugging](#).

[Send comments about this topic to Microsoft](#)

# !minipkd.lun

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.lun** extension displays detailed information about the specified Logical Unit Extension (LUN).

```
!minipkd.lun LUN
!minipkd.lun Device
```

## Parameters

### *LUN*

Specifies the address of the LUN.

### *Device*

Specifies the physical device object (PDO) for the LUN.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

## Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

A LUN is typically referred to as a *device*. Thus, this extension displays information about a device on an adapter.

The LUN can be specified either by its address (which can be found in the **LUN** field of the [!minipkd.adapters](#) display), or by its physical device object (which can be found in the **DevObj** field of the [!minipkd.adapters](#) display).

[Send comments about this topic to Microsoft](#)

# !minipkd.portconfig

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.portconfig** extension displays information about the specified PORT\_CONFIGURATION\_INFORMATION data structure.

```
!minipkd.portconfig PortConfig
```

## Parameters

### *PortConfig*

Specifies the address of a PORT\_CONFIGURATION\_INFORMATION data structure.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

## Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

The *PortConfig* address can be found in the **Port Config Info** field of the [!minipkd.adapter](#) display.

[Send comments about this topic to Microsoft](#)

# !minipkd.req

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.req** extension displays information about all of the currently active requests on the specified adapter or device.

```
!minipkd.req Adapter
!minipkd.req Device
```

## Parameters

### *Adapter*

Specifies the address of the adapter.

### *Device*

Specifies the physical device object (PDO) for the Logical Unit Extension (LUN) device.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

## Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

The PDO for a LUN can be found in the **DevObj** field of the [!minipkd.adapters](#) display.

[Send comments about this topic to Microsoft](#)

# !minipkd.srb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!minipkd.srb** extension displays the specified SCSI request block (SRB) data structure.

```
!minipkd.srb SRB
```

## Parameters

### *SRB*

Specifies the address of an SRB.

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Minipkd.dll |

### Additional Information

For more information, see [SCSI Miniport Debugging](#).

## Remarks

The addresses of all currently active requests can be found in the *SRB* fields of the output from the **!minipkd.req** command.

This extension displays the status of the SRB, the driver it is addressed to, the SCSI that issued the SRB and its address, and a hexadecimal flag value. If 0x10000 is set in the flag value, this request is currently in the miniport.

[Send comments about this topic to Microsoft](#)

# Windows Driver Framework Extensions (Wdfkd.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands that are useful for debugging drivers built with the Kernel-Mode Driver Framework (KMDF) or version 2 of the User-Mode Driver Framework (UMDF 2) are implemented in Wdfkd.dll.

These extensions can be used on Microsoft Windows XP and later operating systems. Some extensions have additional restrictions; these restrictions are noted on the individual reference pages.

**Note** When you create a new KMDF or UMDF driver, you must select a driver name that has 32 characters or less. This length limit is defined in wdfglobals.h. If your driver name exceeds the maximum length, your driver will fail to load.

For more information about how to use these extensions, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.help** extension displays help information about all Wdfkd.dll extension commands.

```
!wdfkd.help
```

## DLL

Wdfkd.dll

## Additional Information

The **!wdfkd.help** extension is equivalent to the [!wdfkd.wdfhelp](#) extension.

For more information about debugging framework-based drivers, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfchildlist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfchildlist** extension displays a child list's state and information about all of the device identification descriptions that are in the child list.

```
!wdfkd.wdfchildlist Handle
```

## Parameters

### Handle

A WDFCHILDLIST-typed handle to the child list.

### DLL

Wdfkd.dll

### Frameworks

KMDF 1

### Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The following example shows a **!wdfkd.wdfchildlist** display.

```
kd> !wdfchildlist 0x7cc090c8
Dumping WDFCHILDLIST 0x7cc090c8

owning !WDFDEVICE 0x7ca7b1c0
ID description size 0x8

State:

List is unlocked, changes will be applied immediately
No scans or enumerations are active on the list

Descriptions:

PDO !WDFDEVICE 0x7cad31c8, ID description 0x83ac4ff4
+Device WDM !devobj 0x81fb00e8, WDF pnp state WdfDevStatePnpStarted (0x119)
+Device found in last scan

No pending insertions are in the list.

Callbacks:

EvtChildListCreateDevice: wdfrawbusenumtest!RawBus_RawPdo_Create (f22263b0)
```

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfcollection

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfcollection** extension displays all of the objects that are stored in a WDFCOLLECTION structure.

`!wdfkd.wdfcollection Handle`

## Parameters

### *Handle*

A WDFCOLLECTION-typed handle to the structure.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfcommonbuffer

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfcommonbuffer** extension displays information about a WDF common buffer object.

```
!wdfkd.wdfcommonbuffer Handle
```

## Parameters

### *Handle*

A handle to a framework common buffer object (WDFCOMMONBUFFER).

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfcrashdump

5/31/2017 • 2 min to read • [Edit Online](#)

The **!wdfkd.wdfcrashdump** extension displays error log information and other crash dump information from a minidump file, if the data is present.

KMDF

```
!wdfkd.wdfcrashdump [InfoType]
```

UMDF

```
!wdfkd.wdfcrashdump [DriverName.dll][-d | -f | -m]
```

## Parameters

### *InfoType*

Specifies the kind of information to display. *InfoType* is optional and can be any one of the following values:

#### **log**

Displays error log information, if available in the crash dump file. This is the default value.

#### **loader**

Displays the minidump's dynamic-bound drivers.

### *DriverName.dll*

Specifies the name of a UMDF driver. You must include the .dll file suffix. If this optional parameter is omitted, output includes metadata, the loaded module list, and available logs.

#### **-d**

Displays only the driver logs.

#### **-f**

Displays only the framework logs.

#### **-m**

Merges framework and driver logs in their recorded order.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF

UMDF 2.15

## Remarks

This example shows how to use **!wdfkd.wdfcrashdump** to view information about KMDF drivers. If you specify **loader** for *InfoType*, the output includes dynamic-bound drivers in the minidump file.

```

0: kd> !wdfcrashdump loader
Retrieving crashdump loader information...
Local buffer 0x002B4D00, bufferSize 720

 ImageName Version FxGlobals

 Wdf01000 v1.9(6902)
 msisadvr v1.9(6913) 0x84deb260
 vdrvroot v1.9(6913) 0x860e8260
 storflt v1.5(6000) 0x861dfe90
 cdrom v1.9(6913) 0x84dca008
 intelppm v1.9(6913) 0x864704a8
 HDAudBus v1.7(6001) 0x86101c98
 1394ohci v1.7(6001) 0x8610d2e8
 CompositeBus v1.9(6913) 0x86505b98
 ObjTestClassExt v1.9(6902) 0x865b7f00
 mqfilter v1.9(6902) 0x865b8008
 mqueue v1.9(6902) 0x865b6910
 umbus v1.9(6913) 0x8618aea0
 monitor v1.9(6913) 0x86aac1d8
 PEAUTH v1.5(6000) 0x854e5350

```

This example shows how to use **!wdfkd.wdfcrashdump** to view information about UMDF drivers. If you issue **!wdfkd.wdfcrashdump** with no parameters, the output includes the driver that caused the crash and a list of all loaded drivers in the host process that failed. You can click on drivers in this list that have associated logs.

```

0:001> !wdfkd.wdfcrashdump
Opening minidump at location C:\temp\WudfHost_ext__1312.dmp

Faulting driver: wpptest.dll
Failure type: Unhandled Exception (WUDFUnhandledException)
Faulting thread ID: 2840

Listing all drivers loaded in this host process at the time of the failure:

 ServiceName
 wpptest
 CoverageCx0102
 coverage
 WUDFVhidmini
 ToastMon
 WUDFOsrUsbFilter

```

In the example above, output includes failure type, which is the event type in the WER report. Here, it can be **WUDFVerifierFailure** or **WUDFUnhandledException**. For more information, see [Accessing UMDF Metadata in WER Reports](#). The output for UMDF includes an error code, if event type is **WUDFVerifierFailure**.

To display the framework's error log records from a [complete memory dump](#), a [kernel memory dump](#), or a [live kernel-mode target](#), you can also try the **!wdfkd.wdflogdump** extension.

## Additional Information

For information about enabling the inflight trace recorder for your driver, see [Using Inflight Trace Recorder \(IFR\) in KMDF and UMDF 2 Drivers](#). For more information about debugging WDF drivers, see [Debugging WDF Drivers](#). For information about KMDF debugging, see [Kernel-Mode Driver Framework Debugging](#).

Send comments about this topic to Microsoft

# !wdfkd.wdfdevext

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfdevext** extension displays information that is associated with the **DeviceExtension** member of a Microsoft Windows Driver Model (WDM) DEVICE\_OBJECT structure.

```
!wdfkd.wdfdevext DeviceExtension
```

## Parameters

### *DeviceExtension*

A pointer to a device extension.

### DLL

Wdfkd.dll

### Frameworks

KMDF 1, UMDF 1, UMDF 2

### Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

Here is an example for HdAudBus.sys, which is a KMDF driver. Use **!devnode** to find a device node that has HdAudBus as its function driver. Take the physical device object (PDO) from the output and pass it to **!devstack**. Take the device extension address from the output of **!devstack** and pass it to **!wdfdevext**.

```

# !wdfkd.wdfdevice

5/31/2017 • 2 min to read • [Edit Online](#)

The **!wdfkd.wdfdevice** extension displays information that is associated with a WDFDEVICE-typed object handle.

```
!wdfkd.wdfdevice Handle [Flags]
```

## Parameters

### *Handle*

A handle to a WDFDEVICE-typed object.

### *Flags*

Optional. The kind of information to display. *Flags* can be any combination of the following bits:

Bit 0 (0x1)

The display will include verbose information about the device, such as the associated WDFCHILDLIST-typed handles, synchronization scope, and execution level.

Bit 1 (0x2)

The display will include detailed power state information.

Bit 2 (0x4)

The display will include detailed power policy state information.

Bit 3 (0x8)

The display will include detailed Plug and Play (PnP) state information.

Bit 4 (0x10)

The display will include the device object's callback functions.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The following example uses the **!wdfkd.wdfdevice** extension on a WDFDEVICE handle that represents a physical device object (PDO), without specifying any flags.

```
kd> !wdfdevice 0x7cad31c8

Dumping WDFDEVICE 0x7cad31c8
=====
WDM PDEVICE_OBJECTs: self 81fb00e8

Pnp state: 119 (WdfDevStatePnpStarted)
Power state: 31f (WdfDevStatePowerDx)
Power Pol state: 508 (WdfDevStatePwrPolWaitingUnarmed)

Parent WDFDEVICE 7ca7b1c0
Parent states:
 Pnp state: 119 (WdfDevStatePnpStarted)
 Power state: 307 (WdfDevStatePowerD0)
 Power Pol state: 565 (WdfDevStatePwrPolStarted)

No pended pnp or power irps
Device is the power policy owner for the stack
```

The following example displays the same device object as the preceding example, but this time with a flag value of 0xF. This flag value, a combination of the bits 0x1, 0x2, 0x4, and 0x8, causes the display to include verbose device information, power state information, power policy state information, and PnP state information.

```

kd> !wdfdevice 0x7cad31c8 f

Dumping WDFDEVICE 0x7cad31c8
=====
WDM PDEVICE_OBJECTs: self 81fb00e8

Pnp state: 119 (WdfDevStatePnpStarted)

# !wdfkd.wdfdeviceinterrupts

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfdeviceinterrupts** extension displays all the interrupt objects for a specified device handle.

```
!wdfkd.wdfdeviceinterrupts Handle
```

## Parameters

### *Handle*

A handle to a WDFDEVICE-typed object.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfdevicequeues

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfdevicequeues** extension displays information about all of the framework queue objects that belong to a specified device.

```
!wdfkd.wdfdevicequeues Handle
```

## Parameters

### *Handle*

A handle to a WDFDEVICE-typed object.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#) and [!wdfkd.wdfqueue](#).

## Remarks

The following example shows the display from the **!wdfkd.wdfdevicequeues** extension.

```
kd> !wdfdevicequeues 0x7cad31c8

Dumping queues of WDFDEVICE 0x7cad31c8
=====
Number of queues: 3

Queue: 1 (!wdfqueue 0x7d67d1e8)
 Manual, Not power-managed, PowerOn, Can accept, Can dispatch, ExecutionLevelDispatch,

# !wdfkd.wdfdmaenabler

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfdmaenabler** extension displays information about a WDF direct memory access (DMA) object, and its transaction and common buffer objects.

```
!wdfkd.wdfdmaenabler Handle
```

## Parameters

### *Handle*

A handle to a framework DMA enabler object (WDFDMAENABLER).

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfdmaenablers

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfdmaenablers** extension displays all WDF direct memory access (DMA) objects associated with a specified device object. It also displays their associated transaction and common buffer objects.

```
!wdfkd.wdfdmaenablers Handle
```

## Parameters

### *Handle*

A handle to a framework device object (WDFDEVICE).

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfmatransaction

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfmatransaction** extension displays information about a WDF direct memory access (DMA) transaction object.

```
!wdfkd.wdfmatransaction Handle
```

## Parameters

### *Handle*

A handle to a framework DMA transaction object (WDFDMA TRANSACTION).

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfdriverinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfdriverinfo** extension displays information about the specified driver, including its device tree, the version of the Kernel-Mode Driver Framework (KMDF) library that the driver was compiled with, and a list of the framework device objects that the driver created.

```
!wdfkd.wdfdriverinfo [DriverName [Flags]]
```

## Parameters

### *DriverName*

Optional. The name of the driver. *DriverName* must not include the .sys file name extension.

### *Flags*

Optional. Flags that specify the kind of information to display. *Flags* can be any combination of the following bits:

#### Bit 0 (0x1)

The display will include verifier settings for the driver, and will also include a count of WDF objects. This flag can be combined with bit 6 (0x40) to display internal objects.

#### Bit 4 (0x10)

The display will include the KMDF handle hierarchy for the driver.

#### Bit 5 (0x20)

The display will include context and callback function information for each handle. This flag is valid only when bit 4 (0x10) is set.

#### Bit 6 (0x40)

The display will include additional information for each handle. This flag is valid only when bit 4 (0x10) is set. This flag can be combined with bit 0 (0x1) to display internal objects.

#### Bit 7 (0x80)

The handle information will be displayed in a more compact format.

#### Bit 8 (0x100)

The display will left align internal type information. This flag is valid only when bit 4 (0x10) is set.

#### Bit 9 (0x200)

The display will include handles that the driver potentially leaked. KMDF version 1.1 and later support this flag. This flag is valid only when bit 4 (0x10) is set.

#### Bit 10 (0x400)

The display will include the device tree in verbose form.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

If you omit the *DriverName* parameter, the default driver is used. You can display the default driver by using the **!wdfkd.wdfgetdriver** extension; you can set the default driver by using the **!wdfkd.wdfsetdriver** extension.

The following example shows the display from the **!wdfkd.wdfdriverinfo** extension.

```
kd> !wdfdriverinfo wdfrawbusenumtest

Default driver image name: wdfrawbusenumtest
WDF library image name: Wdf01000
FxDriverGlobals 0x83b7af18
WdfBindInfo 0xf22250ec
Version v1.5 build(1234)

WDFDRIVER: 0x7cbc90d0

!WDFDEVICE 0x7ca7b1c0
 context: dt 0x83584ff8 ROOT_CONTEXT (size is 0x1 bytes)
 <no associated attribute callbacks>

!WDFDEVICE 0x7cad31c8
 context: dt 0x8352cff0 RAW_PDO_CONTEXT (size is 0xc bytes)
 <no associated attribute callbacks>
```

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfextendwatchdog

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfextendwatchdog** extension extends the time-out period (from 10 minutes to 24 hours) of the framework's watchdog timer during power transitions.

```
!wdfkd.wdfextendwatchdog Handle [Extend]
```

## Parameters

### *Handle*

A handle to a WDFDEVICE-typed object.

### *Extend*

Optional. A value that indicates whether to enable or disable extension of the time-out period. If *Extend* is 0, extension is disabled, and the time-out period is 10 minutes. If *Extend* is 1, extension is enabled and the time-out period is 24 hours. The default value is 1.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The framework starts an internal watchdog timer every time it calls a power policy or power event callback function for a driver that is not power pageable (that is, the DO\_POWER\_PAGABLE bit is clear). If the callback function causes paging I/O and therefore blocks, the operating system hangs because no paging device is available to service the request.

If the time-out period elapses, the framework issues bug check 0x10D (WDF\_VIOLATION). For details, see [Bug Check 0x10D](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdffindobjects

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdffindobjects** extension searches memory for WDF objects.

```
!wdfkd.wdffindobjects [StartAddress [Flags]]
```

## Parameters

### *StartAddress*

Optional. Specifies the address at which the search must begin. If this is omitted, the search will begin from where the most recent **!wdfkd.wdffindobjects** search ended.

### *Flags*

Optional. Specifies the kind of information to display. *Flags* can be any combination of the following bits. The default value is 0x0. *Flags* cannot be used unless *StartAddress* is specified.

Bit 0 (0x1)

Displays verbose output.

Bit 1 (0x2)

Displays internal type information for each handle.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The following examples show the output of the **!wdfkd.wdffindobjects** extension. The 0x1 flag is set in the second example.

```

# !wdfkd.wdfforwardprogress

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfforwardprogress** extension displays information about the forward progress of a specified framework queue object.

```
!wdfkd.wdfforwardprogress Handle
```

## Parameters

### *Handle*

A handle to a framework queue object.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1

### **Additional Information**

For more information about how to debug Kernel-Mode Driver Framework (KMDF) drivers, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

This extension will succeed only if the specified framework queue object is configured to support forward progress. If this extension is used with other objects, an error message will be displayed.

The following example shows the display from a **!wdfkd.wdfforwardprogress** extension.

```

kd> !wdfkd.wdfforwardprogress 0x79af3250

# !wdfkd.wdfgetdriver

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfgetdriver** extension displays the name of the current default driver.

```
!wdfkd.wdfgetdriver
```

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfhandle

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfhandle** extension displays information about a specified framework object handle, such as the handle type, object context pointers, and the underlying framework object pointer.

```
!wdfkd.wdfhandle Handle [Flags]
```

## Parameters

### *Handle*

A handle to a framework object.

### *Flags*

Optional. Flags that specify the kind of information to display. *Flags* can be any combination of the following bits. The default value is 0x0.

Bit 4 (0x10)

The display will include the subtree of child objects for the specified handle.

Bit 5 (0x20)

The display will include context and callback function information for the specified handle. This flag is valid only when bit 4 (0x10) is set.

Bit 6 (0x40)

The display will include additional information for the specified handle. This flag is valid only when bit 4 (0x10) is set.

Bit 7 (0x80)

The handle information will be displayed in a more compact format.

Bit 8 (0x100)

The display will left align internal type information. This flag is valid only when bit 4 (0x10) is set.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The following example shows the output of the **!wdfhandle** extension with bit 4 set in the *Flags* parameter (so the output displays information about the child objects).

```
kd> !wdfhandle 0x7ca7b1c0 10

handle 0x7ca7b1c0, type is WDFDEVICE

Contexts:
 context: dt 0x83584ff8 ROOT_CONTEXT (size is 0x1 bytes)
 <no associated attribute callbacks>

Child WDFHANDLEs of 0x7ca7b1c0:
 WDFDEVICE 0x7ca7b1c0
 WDFCMRESLIST 0x7ccfb058
 WDFCMRESLIST 0x7cadb058
 WDFCHILDLIST 0x7c72f0c8
 WDFCHILDLIST 0x7cc090c8
 WDFIOTARGET 0x7c9630b8

!wdfobject 0x83584e38
```

In the preceding example, the input handle refers to a WDFDEVICE object. This particular device object has five child objects--two WDFCMRESLIST objects, two WDFCHILDLIST objects, and one WDFIOTARGET object.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfhelp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfhelp** extension displays help information about all Wdfkd.dll extension commands.

```
!wdfkd.wdfhelp
```

## DLL

Wdfkd.dll

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The **!wdfkd.wdfhelp** extension is equivalent to the [!wdfkd.help](#) extension.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfinterrupt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfinterrupt** extension displays information about a WDFINTERRUPT object.

```
!wdfkd.wdfinterrupt Handle [Flags]
```

## Parameters

### *Handle*

A handle to a WDFINTERRUPT object.

### *Flags*

Optional. Specifies the kind of information to display. *Flags* can be any combination of the following bits. The default value is 0x0.

Bit 0 (0x1)

Displays the interrupt service routines (ISRs) for the interrupt dispatch table (IDT) associated with this WDFINTERRUPT object. Setting this flag is equivalent to following the **!wdfinterrupt** extension with the **!idt** extension.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The following example shows the output of the **!wdfinterrupt** extension with bit 0 set in the *Flags* parameter (so the output displays information about the IDT).

```

kd> !wdfkd.wdfinterrupt 0x7a988698 1

dt nt!KINTERRUPT 0x8594eb28

EvtInterruptIsr: 1394ohci!Interrupt::WdfEvtInterruptIsr (0x8d580552)
EvtInterruptDpc: 1394ohci!Interrupt::WdfEvtInterruptDpc (0x8d580682)

Dumping IDT:

a1: 85167a58 ndis!ndisMiniportIsr (KINTERRUPT 85167a00)
 Wdf01000!FxInterrupt::_InterruptThunk (KINTERRUPT 85987500)

To get ISR from KINTERRUPT:
dt <KINTERRUPT> nt!KINTERRUPT ServiceContext
dt <ServiceContext> wdf01000!FxInterrupt m_EvtInterruptIsr

```

In the preceding example, the display concludes with two suggested **dt (Display Type)** commands that can be used to display additional data.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfiotarget

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfiotarget** extension displays information about a specified I/O target object.

```
!wdfkd.wdfiotarget Handle [Flags]
```

## Parameters

### *Handle*

A handle to an I/O target object.

### *Flags*

Optional. Flags that specify the kind of information to display. *Flags* can be any combination of the following bits. The default value is 0x0.

Bit 0 (0x1)

The display will include details for each of the I/O target's pending request objects.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The following example shows a display from the **!wdfkd.wdfiotarget** extension.

```
kd> !wdfiotarget 0x7c9630b8

WDFIOTARGET 8369cf40
=====
WDFDEVICE: 0x7ca7b1c0
Target Device: !devobj 0x81ede5d8
Target PDO: !devobj 0x822b8a90

Type: Instack target
State: WdfIoTargetStarted

Requests waiting: 0

Requests sent: 0

Requests sent with ignore-target-state: 0
```

The output in the preceding example includes the address of the I/O target's parent framework device object, along with the addresses of the WDM DEVICE\_OBJECT structures that represent the target driver's device object and the target device's physical device object (PDO).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfldr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfldr** extension displays information about the drivers that are currently dynamically bound to the Windows Driver Frameworks. This includes both the Kernel-Mode Driver Framework (KMDF) and the User-Mode Driver Framework (UMDF).

```
!wdfkd.wdfldr [DriverName]
```

## Parameters

### *DriverName*

The name of a driver, including the filename extension. If you supply a driver name, this command displays detailed information about the one driver. If you do not supply a drive name, this command displays information about all drivers that are bound to the Windows Driver Frameworks.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

Here is an example of the output of **!wdfldr**.

```

0: kd> !wdfldr.wdfldr

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdflogdump

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdflogdump** extension displays the WDF In-flight Recorder log records, if available, for a KMDF driver or a UMDF 2 driver. You can use this command with a [complete memory dump](#), a [kernel memory dump](#), or a [live kernel-mode target](#).

KMDF

```
!wdfkd.wdflogdump [DriverName][WdfDriverGlobals][-d | -f | -a LogAddress]
```

UMDF

```
!wdfkd.wdflogdump [DriverName.dll][HostProcessId][-d | -f | -m]
```

## Parameters

*DriverName*

- KMDF: The name of a KMDF driver. The name must not include the .sys filename extension.
- UMDF: The name of a UMDF 2 driver. The name must include the .dll filename extension.

*Parameter2*

- KMDF: *WdfDriverGlobals* - The address of the *WdfDriverGlobals* structure. You can determine this address by running **!wdfkd.wdfldr** and looking for the field labeled "WdfGlobals". Or, you can supply @@(Driver!WdfDriverGlobals) as the address value, where *Driver* is the name of the driver. If any *WdfDriverGlobals* address is supplied, *DriverName* is ignored (although it must nevertheless be supplied).
- UMDF: *HostProcessId* - The process ID of an instance of wudfhost.exe. If you supply the process ID, this command displays the log records for that process. If you do not supply the process ID, this command displays a list of commands in this form:

**!wdflogdump** *DriverName* \*\*\*\* *ProcessID*

If a single process can be determined it will automatically be chosen.

*Options*

KMDF:

**-d** Displays only the driver logs.

**-f** Displays only the framework logs.

**-a** *LogAddress* Displays a specific driver log. If this option is used, the *LogAddress* must be provided.

UMDF:

**-d** Displays only the driver logs.

**-f** Displays only the framework logs.

**-m** Merges framework and driver logs in their recorded order.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Remarks

If you omit the *DriverName* parameter, the default driver name is used. Use the [!wdfkd.wdfgetdriver](#) extension to display the default driver name, and use the [!wdfkd.wdfsetdriver](#) extension to set the default driver name.

To display the framework's error log records from a [small memory dump](#), use the [!wdfkd.wdfcrashdump](#) extension.

For information about setting information that the debugger needs to format WPP tracing messages, see [!wdfkd.wdftmfile](#) and [!wdfkd.wdfsettraceprefix](#).

## Additional Information

For information about enabling the inflight trace recorder for your driver, see [Using Inflight Trace Recorder \(IFR\) in KMDF and UMDF 2 Drivers](#). For more information about debugging WDF drivers, see [Debugging WDF Drivers](#). For information about KMDF debugging, see [Kernel-Mode Driver Framework Debugging](#).

## See also

[!wdfkd.wdfcrashdump](#)

[!wdfkd.wdfsettraceprefix](#)

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdflogsave

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdflogsave** extension saves the Kernel-Mode Driver Framework (KMDF) error log records for a specified driver to an event trace log (.etl) file that you can view by using TraceView.

```
!wdfkd.wdflogsave [DriverName [FileName]]
```

## Parameters

### *DriverName*

Optional. The name of a driver. *DriverName* must not include the .sys file name extension.

### *FileName*

Optional. The name of the file to which the KMDF error log records should be saved. *FileName* should not include the .etl file name extension. If you omit *FileName*, the KMDF error log records are saved to the *DriverName.etl* file.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

If you omit the *DriverName* parameter, the default driver name is used. Use the [!wdfkd.wdfgetdriver](#) extension to display the default driver name, and use the [!wdfkd.wdfsetdriver](#) extension to set the default driver name.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfmemory

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfmemory** extension displays the address and size of the buffer that is associated with a framework memory object.

```
!wdfkd.wdfmemory Handle
```

## Parameters

### *Handle*

A handle to a framework memory object.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfobject

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfobject** extension displays information about a specified framework object.

```
!wdfkd.wdfobject FrameworkObject
```

## Parameters

*FrameworkObject*

A pointer to a framework object.

### DLL

Wdfkd.dll

### Frameworks

KMDF 1, UMDF 2

### Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

If the Kernel-Mode Driver Framework (KMDF) verifier is enabled for a driver and the public handle type was marked for tracking, the display from the **!wdfkd.wdfobject** extension includes the tag tracker (that is, the tracking object), as in the following example.

```
kd> !wdfobject 0x83584e38

The type for object 0x83584e38 is FxDevice
State: FxObjectStateCreated (0x1)

!wdffhandle 0x7ca7b1c0

dt FxDevice 0x83584e38

 context: dt 0x83584ff8 ROOT_CONTEXT (size is 0x1 bytes)
 <no associated attribute callbacks>

Object debug extension 83584e20
 !wdftagtracker 0x83722d80
 Verifier lock 0x831cefa8

 State history:
 [0] FxObjectStateCreated (0x1)
```

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfopenhandles

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfopenhandles** extension displays information about all the handles that are open on the specified WDF device.

```
!wdfkd.wdfopenhandles Handle [Flags]
```

## Parameters

### *Handle*

A handle to a framework device object (WDFDEVICE).

### *Flags*

Optional. Specifies the kind of information to display. *Flags* can be any combination of the following bits. The default value is 0x0.

Bit 0 (0x1)

Displays file object context information.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfpool

5/26/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfpool** extension is obsolete.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfpooltracker

5/26/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfpooltracker** extension is obsolete.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfpoolusage

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfpoolusage** extension displays pool usage information for a specified driver, if the Kernel-Mode Driver Framework (KMDF) verifier is enabled for the driver.

```
!wdfkd.wdfpoolusage [DriverName [SearchAddress] [Flags]]
```

## Parameters

### *DriverName*

Optional. The name of a driver. *DriverName* must not include the .sys file name extension.

### *SearchAddress*

Optional. A string that represents a memory address. The pool entry that contains *SearchAddress* is displayed. If *SearchAddress* is 0 or omitted, all of the driver's pool entries are displayed.

### *Flags*

Optional. The kind of information to display. This parameter is valid only if *SearchAddress* is nonzero. *Flags* can be any combination of the following bits. The default value is 0x0.

Bit 0 (0x1)

Displays verbose output. Multiple lines are displayed for each. If this flag is not set, the information about an allocation is displayed on one line.

Bit 1 (0x2)

Displays internal type information for each handle.

Bit 2 (0x4)

Displays the caller of each pool entry.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

If you omit the *DriverName* parameter, the default driver is used. You can display the default driver by using the **!wdfkd.wdfgetdriver** extension; you can set the default driver by using the **!wdfkd.wdfsetdriver** extension.

The following example shows the output from the **!wdfpoolusage** extension when no pool allocation is marked and the *Flags* value is set to 0.

```
kd> !wdfpoolusage wdfrawbusenumtest 0 0

FxDriverGlobals 83b7af18 pool stats

Driver Tag: 'RawB'
15126 NonPaged Bytes, 548 Paged Bytes
94 NonPaged Allocations, 10 Paged Allocations
15610 PeakNonPaged Bytes, 752 PeakPaged Bytes
100 PeakNonPaged Allocations, 14 PeakPaged Allocations

pool 82dbae00, Size 512 Tag 'RawB', NonPaged, Caller: Wdf01000!FxVerifierLock::AllocateThreadTable+5d
```

The following example shows the output from **!wdfpoolusage** that appears when the value of *Flags* is 1. (Note that the ellipsis (...) on the second line indicates the omission of some output that is the same as that shown in the preceding example.)

```
kd> !wdfpoolusage wdfrawbusenumtest 0 1
...
100 PeakNonPaged Allocations, 14 PeakPaged Allocations

Client alloc starts at 82dbae00
Size 512 Tag 'RawB'
NonPaged (0x0)
Caller: Wdf01000!FxVerifierLock::AllocateThreadTable+5d
```

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfqueue

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfqueue** extension displays information about a specified framework queue object and the framework request objects that are in the queue.

```
!wdfkd.wdfqueue Handle
```

## Parameters

### *Handle*

A handle to a framework queue object.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The following example shows the display from a **!wdfkd.wdfqueue** extension.

```
kd> !wdfqueue 0x7ce7d1e8
Dumping WDFQUEUE 0x7ce7d1e8
=====
Parallel, Power-managed, PowerOff, Can accept, Can dispatch, ExecutionLevelDispatch, SynchronizationScopeNone
Number of driver owned requests: 0
Number of waiting requests: 0

EvtIoDefault: (0xf221fad0) wdfrawbusenumtest!EvtIoQueueDefault
```

The queue in the preceding example is configured for parallel dispatching, is power-managed but is currently in the Off state, and can both accept and dispatch requests.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfrequest

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfrequest** extension displays information about a specified framework request object and the WDM I/O request packet (IRP) that is associated with the request object.

```
!wdfkd.wdfrequest Handle
```

## Parameters

### *Handle*

A handle to a framework request object.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfsearchpath

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfsearchpath** extension sets the search path to formatting files for Kernel-Mode Driver Framework (KMDF) error log records.

```
!wdfkd.wdfsearchpath Path
```

## Parameters

### *Path*

The path of a directory that contains KMDF formatting files.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The KMDF formatting files are included in the Windows Driver Kit (WDK). The path to the formatting files depends on the installation directory of your WDK and on the version of the WDK that you have installed. The KMDF formatting files have extension tmf (trace message formatting). To determine the search path, browse or search your WDK installation for file names of the form *WdfVersionNumber.tmf*. The following example shows how to use the **!wdfkd.wdfsearchpath** extension.

```
kd> !wdfsearchpath C:\WinDDK\7600\tools\tracing\amd64
```

The TRACE\_FORMAT\_SEARCH\_PATH environment variable also controls the search path, but the **!wdfkd.wdfsearchpath** extension takes precedence over the search path that TRACE\_FORMAT\_SEARCH\_PATH specifies.

## Requirements

|     |           |
|-----|-----------|
| DLL | Wdfkd.dll |
|-----|-----------|

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfsettraceprefix

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfsettraceprefix** extension sets the trace prefix format string.

```
!wdfkd.wdfsettraceprefix String
```

## Parameters

*String*

A trace prefix string.

### DLL

Wdfkd.dll

### Frameworks

KMDF 1, UMDF 2

### Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The trace prefix string is prepended to each trace message in the Kernel-Mode Driver Framework (KMDF) error log. The TRACE\_FORMAT\_PREFIX environment variable also controls the trace prefix string.

The format of the trace prefix string is defined by the Microsoft Windows tracing tools. For more information about the format of this string and how to customize it, see the "Trace Message Prefix" topic in the Driver Development Tools section of the Windows Driver Kit (WDK).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfsetdriver

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfsetdriver** extension sets the name of the default Kernel-Mode Driver Framework (KMDF) driver to which debugger extension commands apply.

```
!wdfkd.wdfsetdriver DriverName
```

## Parameters

### *DriverName*

The name of a driver. *DriverName* must not include the .sys file name extension.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

The **!wdfkd.wdfsetdriver** extension sets the default driver name. You can use this name with other **wdfkd** extensions that would otherwise require you to specify a driver name.

To obtain the name of the current default KMDF driver, use the [!wdfkd.wdfgetdriver](#) extension.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfspinlock

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfspinlock** extension displays information about a framework spin-lock object. This information includes the spin lock's acquisition history and the length of time that the lock was held.

```
!wdfkd.wdfspinlock Handle
```

## Parameters

### *Handle*

A handle to a WDFSPINLOCK-typed object.

### **DLL**

Wdfkd.dll

### **Frameworks**

KMDF 1, UMDF 2

### **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdftagtracker

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdftagtracker** extension displays all available tag information (including tag value, line, file, and time) for a specified tag tracker.

```
!wdfkd.wdftagtracker TagObjectPointer [Flags]
```

## Parameters

### *TagObjectPointer*

A pointer to a tag tracker.

### *Flags*

Optional. The kind of information to display. *Flags* can be any combination of the following bits. The default value is 0x0.

Bit 0 (0x1)

Displays the history of acquire operations and release operations on the object.

Bit 1 (0x2)

Displays the line number of the object in hexadecimal instead of decimal.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

To retrieve a pointer to a tag tracker, use the [!wdfkd.wdfobject](#) extension on an internal framework object pointer.

To use tag tracking, you must enable both the Kernel-Mode Driver Framework (KMDF) verifier and handle tracking in the registry. Both of these settings are stored in the driver's **Parameters\Wdf** subkey of the

**HKEY\_LOCAL\_MACHINE\System\CurrentControlSet\Services** key.

To enable the KMDF verifier, set a nonzero value for **VerifierOn**.

To enable handle tracking, set the value of **TrackHandles** to the name of one or more object types, or specify an asterisk (\*) to track all object types. For example, the following example specifies the tracking of references to all WDFDEVICE and WDFQUEUE objects.

```
TrackHandles: MULTI_SZ: WDFDEVICE WDFQUEUE
```

When you enable handle tracking for an object type, the framework tracks the references that are taken on any object of that type. This setting is useful in finding driver memory leaks that unreleased references cause.

**TrackHandles** works only if the KMDF verifier is enabled.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdftmffile

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdftmffile** extension sets the trace message format (.tmf) file to use when the debugger is formatting Kernel-Mode Driver Framework (KMDF) error log records for the [!wdfkd.wdflogdump](#) or [!wdfkd.wdfcrashdump](#) extensions.

```
!wdfkd.wdftmffile TMFpath
```

## Parameters

### *TMFpath*

A path that contains the .tmf file.

### DLL

Wdfkd.dll

### Frameworks

KMDF 1, UMDF 2

### Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

If your driver uses a KMDF version earlier than 1.11, you must use the **!wdfkd.wdftmffile** extension before you can use the [!wdfkd.wdflogdump](#) or [!wdfkd.wdfcrashdump](#) extensions.

Starting in KMDF version 1.11, the framework library's symbol file (for example wdf01000.pdb) contains the trace message format (TMF) entries. Starting in the Windows 8 version of the kernel debugger, the [Kernel-Mode Driver Framework Extensions \(Wdfkd.dll\)](#) read the entries from the .pdb file. As a result, if your driver uses KMDF version 1.11 or later, and you are using the kernel debugger from Windows 8 or later, you do not need to use **!wdfkd.wdftmffile**. You do need to include the directory that contains the symbol file in the debugger's [symbol path](#). The debugging target machine can be running any operating system that supports KMDF.

The following example shows how to use the **!wdfkd.wdftmffile** extension from the root WDK directory, for KMDF version 1.5.

```
kd> !wdftmffile tools\tracing\<platform>\wdf1005.tmf
```

Note that the path might be different for the version of the Windows Driver Kit (WDK) that you are using. Also note that the .tmf file's name represents the version of KMDF that you are using. For example, Wdf1005.tmf is the .tmf file for KMDF version 1.5.

For information about how to view the KMDF log during a debugging session, see [Using the Framework's Event Logger](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdftraceprtdebug

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdftraceprtdebug** extension enables and disables the Traceprt.dll diagnostic mode, which generates verbose debugging information.

```
!wdfkd.wdftraceprtdebug {on | off}
```

## Parameters

### on

Enables the Traceprt.dll diagnostic mode.

### off

Disables the Traceprt.dll diagnostic mode.

### DLL

Wdfkd.dll

### Frameworks

KMDF 1, UMDF 2

### Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You should use the !wdfkd.wdftraceprtdebug extension only at the direction of technical support.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfumdevstack

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfumdevstack** extension displays detailed information about a UMDF device stack in the [implicit process](#).

```
!wdfkd.wdfumdevstack DevstackAddress [Flags]
```

## Parameters

### *DevstackAddress*

Specifies the address of the device stack to display information about. You can use [!wdfkd.wdfumdevstacks](#) to get the addresses of UMDF device stacks in the implicit process.

### *Flags*

Optional. Specifies the type of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x01.

Bit 0 (0x01)

Displays detailed information about the device stack.

Bit 7 (0x80)

Displays information about the internal framework.

## DLL

Wdfkd.dll

## Frameworks

UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You can use this command in a kernel-mode debugging session or in a user-mode debugging session that is attached to the UMDF host process (wdfhost.exe).

This command displays the same information as the user-mode command [!wudfext.umdevstack](#).

Here is an example of how to use **!wdfumdevstack**. First use [!wdfumdevstacks](#) to display the UMDF device stacks in the implicit process.

```
0: kd> !wdfkd.wdfumdevstack
Number of device stacks: 1
Device Stack: 0x000000a5a3ab5f70 Pdo Name: \Device\00000052
 Active: Yes
 Number of UM devices: 1
 Device 0
 Driver Config Registry Path: MyUmdf2Driver
 UMDriver Image Path: C:\WINDOWS\System32\drivers\UMDF\MyUmdf2Driver.dll
 FxDriver: 0xa5a3acaaa0
 FxDevice: 0xa5a3ac4fc0
 Open UM files (use !wdfumfile <addr> for details): <None>
 Device XferMode: Deferred RW: Buffered CTL: Buffered
 DevStack XferMode: Deferred RW: Buffered CTL: Buffered
```

The preceding output shows that there is one UMDF device stack in the implicit process. You can also see that the device stack has one device object (Number of UM devices: 1).

The preceding output displays the address of a device stack (0x000000a5a3ab5f70). To get detailed information about the device stack, pass its address to **!wdfumdevstack**. In this example, we set the *Flags* parameter to 0x80 to include information about the framework.

```
0: kd> !wdfkd.wdfumdevstack 0x000000a5a3ab5f70 0x80
Device Stack: 0x000000a5a3ab5f70 Pdo Name: \Device\00000052
 Active: Yes
 Number of UM devices: 1

# !wdfkd.wdfumdevstacks

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfumdevstacks** extension displays information about all UMDF device stacks in the [implicit process](#).

```
!wdfkd.wdfumdevstacks [Flags]
```

## Parameters

### Flags

Optional. Specifies the type of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x01.

Bit 0 (0x01)

Displays detailed information about each device stack.

Bit 7 (0x80)

Displays information about the internal framework.

## DLL

Wdfkd.dll

## Frameworks

UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You can use this command in a kernel-mode debugging session or in a user-mode debugging session that is attached to the UMDF host process (wudfhost.exe).

This command displays the same information as the user-mode command [!wudfext.umdevstacks](#).

Before you use this command, use [!process](#) to get a list of all UMDF host processes.

```
0: kd> !process 0 0 wudfhost.exe
PROCESS fffffe00000c32900
SessionId: 0 Cid: 079c Peb: 7fff782537000 ParentCid: 037c
DirBase: 607af000 ObjectTable: fffffc00009807940 HandleCount: <Data Not Accessible>
Image: WUDFHost.exe
```

The preceding output shows that there is one UMDF host process; that is, there is one instance of wudfhost.exe.

Next use [.process](#) to set the implicit process to wudfhost.exe.

```
0: kd> .process /P fffffe00000c32900
Implicit process is now fffffe000`00c32900
.cache forcedecodeptes done
```

Now use **!wdfkd.wdfumdevstacks** to display the UMDF device stacks in the implicit process (wudfhost.exe).

```
0: kd> !wdfkd.wdfumdevstacks
Number of device stacks: 1
Device Stack: 0x000000a5a3ab5f70 Pdo Name: \Device\00000052
 Active: Yes
 Number of UM devices: 1
 Device 0
 Driver Config Registry Path: MyUmdf2Driver
 UMDriver Image Path: C:\WINDOWS\System32\drivers\UMDF\MyUmdf2Driver.dll
 FxDriver: 0xa5a3acaaa0
 FxDevice: 0xa5a3ac4fc0
 Open UM files (use !wdfumfile <addr> for details): <None>
 Device XferMode: Deferred RW: Buffered CTL: Buffered
 DevStack XferMode: Deferred RW: Buffered CTL: Buffered
```

The preceding output shows that there is one UMDF device stack in the implicit process. You can also see that the device stack has one device object (Number of UM devices: 1).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfumdownirp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfumdownirp** extension displays the kernel-mode I/O request packet (IRP) that is associated with a specified user-mode IRP. This command is used in two steps. See Remarks.

```
!wdfkd.wdfumdownirp UmIrp [FileObject]
```

## Parameters

### *UmIrp*

Specifies the address of a user mode IRP. You can use [!wdfkd.wdfumirps](#) to get the addresses of UM IRPs in the [implicit process](#).

### *FileObject*

Specifies the address of a [\\_FILE\\_OBJECT](#) structure. For information about how to get this address, see Remarks.

## DLL

Wdfkd.dll

## Frameworks

UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You can use this command in a kernel-mode debugging session or in a user-mode debugging session that is attached to the UMDF host process (wudfhost.exe).

To use this command, follow these steps:

1. Enter this command, passing only the address a user-mode IRP. The command displays a handle.
2. Pass the displayed handle to the [!handle](#) command. In the output of [!handle](#), find the address of a [\\_FILE\\_OBJECT](#) structure.
3. Enter this command again, passing both the address of the user-mode IRP and the address of the [\\_FILE\\_OBJECT](#) structure.

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfumfile

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfumfile** extension displays information about a UMDF intra-stack file.

`!wdfkd.wdfumfile Address`

## Parameters

### *Address*

Specifies the address of the UMDF intra-stack file to display information about.

## DLL

Wdfkd.dll

## Frameworks

UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You can use this command in a kernel-mode debugging session or in a user-mode debugging session that is attached to the UMDF host process (wudfhost.exe).

This command displays the same information as the user-mode command [!wudfext.umfile](#).

[Send comments about this topic to Microsoft](#)

# !wdfkd.wdfumirp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfumirp** extension displays information about a user-mode I/O request packet (UM IRP).

`!wdfkd.wdfumirp Address`

## Parameters

### *Address*

Specifies the address of the UM IRP to display information about. You can use **!wdfkd.wdfumirps** to get the addresses of UM IRPs in the [implicit process](#).

## DLL

Wdfkd.dll

## Frameworks

UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You can use this command in a kernel-mode debugging session or in a user-mode debugging session that is attached to the UMDF host process (wudfhost.exe).

This command displays the same information as the user-mode command **!wudfext.umirp**.

You can use **!process** to get a list of all UMDF host processes, and you can use **.process** to set the implicit process to one of the UMDF host processes. For a detailed example, see **!wdfkd.wdfumdevstacks**.

The following shows how to use **!wdfkd.wdfumirps** and **!wdfkd.wdfumirp** to display information about an individual UM IRP.

Send comments about this topic to Microsoft

# !wdfkd.wdfumirps

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfumirps** extension displays the list of pending user-mode I/O request packets (UM IRPs) in the [implicit process](#).

```
!wdfkd.wdfumirps NumberOfIrps Flags
```

## Parameters

### *NumberOfIrps*

Optional. Specifies the number of pending UM IRPs to display information about. If *NumberOfIrps* is an asterisk (\*) or is omitted, all UM IRPs will be displayed.

### *Flags*

Optional. Specifies the type of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x01.

Bit 0 (0x01)

Displays details about the pending IRPs.

## DLL

Wdfkd.dll

## Frameworks

UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You can use this command in a kernel-mode debugging session or in a user-mode debugging session that is attached to the UMDF host process (wdfhost.exe).

This command displays the same information as the user-mode command [!wudfext.umirps](#).

You can use [!process](#) to get a list of all UMDF host processes, and you can use [.process](#) to set the implicit process to one of the UMDF host processes. For a detailed example, see [!wdfkd.wdfumdevstacks](#).

Here is an example of the output of **!wdfkd.wdfumirps**.

```
0: kd> !wdfkd.wdfumirps
Number of pending IRPS: 0x4
CwudfIrp Current Type UniqueId KernelIrp Device Stack
---- -----
0000 1ab9e90c40 WdfRequestUndefined 0 0 1ab9eaa6d0

```

[Send comments about this topic to Microsoft](#)

# !wdfkd\_wdfumtriage

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd\_wdfumtriage** extension displays information about all UMDF devices on the system, including device objects, corresponding host process, loaded drivers and class extensions, PnP device stack, PnP device nodes, dispatched IRPs, and problem state if relevant.

```
!wdfkd.wdfumtriage
```

## DLL

Wdfkd.dll

## Frameworks

UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

## Remarks

You can use this command in a kernel-mode debugging session.

Here is an example of the output of **!wdfkd\_wdfumtriage**.

```

0: kd> !wdfkd.wdfumtriage

# !wdfkd.wdfusbdevice

5/31/2017 • 1 min to read • [Edit Online](#)

The !wdfkd.wdfusbdevice extension displays information about a specified Kernel-Mode Driver Framework (KMDF) USB device object. This information includes all USB interfaces and the pipes that are configured for each interface.

```
!wdfkd.wdfusbdevice Handle [Flags]
```

## Parameters

### *Handle*

A handle to a WDFUSBDEVICE-typed USB device object.

### *Flags*

Optional. A hexadecimal value that modifies the kind of information to return. The default value is 0x0. Flags can be any combination of the following bits:

Bit 0 (0x1)

The display will include the properties of the I/O target.

Bit 1 (0x2)

The display will include the properties of the I/O target for each USB pipe object.

## DLL

Wdfkd.dll

## Frameworks

KMDF 1, UMDF 2

## Additional Information

For more information, see [Kernel-Mode Driver Framework Debugging](#).

# !wdfkd.wdfusbinterface

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wdfkd.wdfusbinterface** extension displays information about a specified Kernel-Mode Driver Framework (KMDF) USB interface object, including its possible and current settings.

```
!wdfkd.wdfusbinterface Handle [Flags]
```

## Parameters

### *Handle*

A handle to a WDFUSBINTERFACE-typed USB interface object.

### *Flags*

Optional. A hexadecimal value that modifies the kind of information to return. The default value is 0x0. Flags can be any combination of the following bits:

Bit 0 (0x1)

The display will include the properties of the I/O target for each KMDF USB pipe object.

## **DLL**

Wdfkd.dll

## **Frameworks**

KMDF 1, UMDF 2

## **Additional Information**

For more information, see [Kernel-Mode Driver Framework Debugging](#).

# User-Mode Driver Framework Extensions (Wudfext.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

Extension commands that are useful for debugging User-Mode Driver Framework drivers are implemented in Wudfext.dll.

You can use the Wudfext.dll extension commands in Microsoft Windows XP and later operating systems. Some extensions have additional restrictions on the Windows version or UMDF version that is required; these restrictions are noted on the individual reference pages.

**Note** When you create a new KMDF or UMDF driver, you must select a driver name that has 32 characters or less. This length limit is defined in wdfglobals.h. If your driver name exceeds the maximum length, your driver will fail to load.

For ways to use these extensions, see [User-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wudfext.help

5/31/2017 • 1 min to read • [Edit Online](#)

# !wudfext.umdevstack

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.umdevstack** extension displays detailed information about a device stack in the host process.

```
!wudfext.umdevstack DevstackAddress [Flags]
```

## Parameters

### *DevstackAddress*

Specifies the address of the device stack to display information about.

### *Flags*

Optional. Specifies the type of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x01.

Bit 0 (0x01)

Displays detailed information about the device stack.

Bit 8 (0x80)

Displays information about the internal framework.

## DLL

|                             |             |
|-----------------------------|-------------|

# !wudfext.umdevstacks

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.umdevstacks** extension displays information about all device stacks in the current host process.

```
!wudfext.umdevstacks [Flags]
```

## Parameters

### Flags

Optional. Specifies the type of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x01.

Bit 0 (0x01)

Displays detailed information about each device stack.

Bit 8 (0x80)

Displays information about the internal framework.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

The **!wudfext.umdevstacks** extension displays the framework interface objects that are associated with each device stack. For more information about using the output from **!wudfext.umdevstacks**, see

### [!wudfext.umdevstack](#).

The **!wudfext.umdevstacks** output includes two fields entitled "Object Tracking" and "RefCount Tracking". These indicate whether the object tracking option (**TrackObjects**) and the reference count tracking option (**TrackRefCounts**) have been enabled in WDF Verifier, respectively. If the object tracking option has been enabled, the display includes the object tracker address; this address can be passed to **!wudfext.wudfdumpobjects** to display tracking information.

Here is an example of the **!wudfext.umdevstacks** display:

```
0: kd> !umdevstacks

### Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wudfext.umirp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.umirp** extension displays information about a host user-mode I/O request packet (UM IRP).

**!wudfext.umirp Address**

## Parameters

### *Address*

Specifies the address of the UM IRP to display information about.

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

### Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

You can use the **!wudfext.umirps** extension command to display a list of all outstanding UM IRPs in the host process.

Each UM IRP has one or more stack locations. Each stack location corresponds to the parameters that a single driver in the device stack will receive when it is called to handle a request.

**!wudfext.umirp** dumps all of the stack locations and marks the current location with a right angle bracket (>). The current location corresponds to the driver that currently owns the request. The current location changes when a driver forwards a request to the next lower driver in the stack, or when the driver completes a request that the driver owns.

The following is an example of the **!wudfext.umirp** display:

```
kd> !umirp 3dd480
UM IRP: 0x003dd480 UniqueId: 0xde Kernel Irp: 0x0x85377850
 Type: WudfMsg_READ

 Offset: 0x0
```

[Send comments about this topic to Microsoft](#)

# !wudfext.umirps

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.umirps** extension displays the list of pending user-mode I/O request packets (UM IRPs) in the host process.

```
!wudfext.umirps NumberOfIrps Flags
```

## Parameters

### *NumberOfIrps*

Optional. Specifies the number of pending UM IRPs to display information about. If *NumberOfIrps* is an asterisk (\*) or is omitted, all UM all UM IRPs will be displayed.

### *Flags*

Optional. Specifies the type of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x01.

Bit 0 (0x01)

Displays details about the pending IRPs.

## DLL

|                      |             |
|----------------------|-------------|
| Windows 2000         | Unavailable |
| Windows XP and later | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

The list of pending UM IRPs that are displayed have either been presented to the driver or are waiting to be presented to the driver.

By default, **!wudfext.umirps** shows all UM IRPs. However, you can use the *NumberOfIrps* parameter to limit this display.

The following is an example of the **!wudfext.umirps** display:

```

kd> !umirps 0xa
Number of pending IRPs: 0xc8
CWudfIrp Type UniqueId KernelIrp
---- -----
0000 3dd280 READ dc 856f02f0

```

To determine the corresponding kernel-mode IRP, use the [!wudfext.wudfdownkmirp](#) extension. Alternatively, you can use the values in the **UniqueId** and **KernelIrp** columns to match a UMDF IRP (or UM IRP) to a corresponding kernel IRP. You can pass the values in the **CWudfIrp** column to the [!wudfext.umirp](#) extension to determine the framework **IWDFRequest** objects that each layer in the device stack can access.

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfdevice

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfdevice** extension displays the Plug and Play (PnP) and power-management state systems for a device.

```
!wudfext.wudfdevice pWDFDevice
```

## Parameters

*pWDFDevice*

Specifies the address of the **IWDFDevice** interface to display PnP or power-management state about.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

You can use the **!wudfext.wudfdevice** extension to determine the current PnP or power-management state of the device that the *pWDFDevice* parameter specifies.

The following is an example of the **!wudfext.wudfdevice** display:

```
kd> !wudfdevice 0xf2f80
Pnp Driver Callbacks:
 IPnpCallback: 0x0
 IPnpCallbackHardware: 0x0

# !wudfext.wudfdevicequeues

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfdevicequeues** extension displays information about all the I/O queues for a device.

```
!wudfext.wudfdevicequeues pWDFDevice
```

## Parameters

*pWDFDevice*

Specifies the address of the **IWDFDevice** interface for which to display information about all of its associated I/O queues. The [!wudfext.wudfdriverinfo](#) extension command determines the address of **IWDFDevice**.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

The following is an example of the **!wudfext.wudfdevicequeues** display:

```
kd> !wudfdevicequeues 0xf2f80

Queue: 1 (!wudfqueue 0x000f3500)
 WdfIoQueueDispatchSequential, POWER MANAGED, WdfIoQueuePowerOn, CAN ACCEPT, CAN DISPATCH

```

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfdownkmirp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.downkmmirp** extension displays the kernel-mode I/O request packet (IRP) that corresponds to the specified user-mode I/O request packet (UM IRP).

```
!wudfext.wudfdownkmirp Address
```

## Parameters

### *Address*

Specifies the address of the UM IRP whose corresponding kernel-mode IRP is to be displayed.

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

### Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

You can use the [!wudfext.umirps](#) extension command to display a list of all outstanding UM IRPs in the host process.

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfdriverinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfdriverinfo** extension displays information about a UMDF driver within the current host process.

```
!wudfext.wudfdriverinfo Name
```

## Parameters

### *Name*

Specifies the name of the UMDF driver to display information about.

### DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

### Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

The **!wudfext.wudfdriverinfo** extension iterates through each level in each device stack and displays the driver and device information for each entry that matches the driver whose name is specified in the *Name* parameter.

You can use **!wudfext.wudfdriverinfo** to quickly find the device object for your driver.

The following is an example of the **!wudfext.wudfdriverinfo** display:

```
kd> !wudfdriverinfo wudfchodriver
IWDFFDriver: 0xf2db8
!WDFDEVICE 0xf2f80
!devstack 0x34e4e0 @ level 0
```

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfdumpobjects

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfdumpobjects** extension displays outstanding UMDF objects.

```
!wudfext.wudfdumpobjects ObjTrackerAddress
```

## Parameters

### *ObjTrackerAddress*

Specifies the address to track leaked objects. This address is displayed in the driver-stop message in the debugger when a leak occurs.

## DLL

|                                                   |             |
|---------------------------------------------------|-------------|
| <b>Windows 2000</b>                               | Unavailable |
| <b>Windows XP with UMDF version 1.7 and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

If the UMDF object tracking option (**TrackObjects**) has been enabled in WDF Verifier, you can use **!wudfext.wudfdumpobjects** to see any leaked objects that remain after the driver unloads.

If the **TrackObjects** option has been enabled, the address of the object tracker is automatically displayed when a leak is detected. Use this address as *ObjTrackerAddress* when executing **!wudfext.wudfdumpobjects**.

This extension can be used at any time, even if UMDF has not broken in to the debugger.

If UMDF is version 1.9 or above, you can use either **!wudfext.umdevstack** or **!wudfext.umdevstacks** to determine the address of the object tracker. This address can then be passed to **!wudfext.wudfdumpobjects**. Here is an example:

```
0: kd> !umdevstacks
Number of device stacks: 1
Device Stack: 0x038c6f08 Pdo Name: \Device\USBPDO-11

# !wudfext.wudffile

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudffile** extension displays information about a framework file.

```
!wudfext.wudffile pWdffile [TypeName]
```

## Parameters

*pWdffile*

Specifies the address of the **IWdffile** interface to display information about.

*TypeName*

Optional. Specifies the type of the interface (for example, **IWDFDevice**). If a value for *TypeName* is supplied, the extension uses the value as the type of the interface. If an asterisk (\*) is supplied as *TypeName*, or if *TypeName* is omitted, the extension attempts to automatically determine the type of the supplied interface.

## DLL

|                                                   |             |
|---------------------------------------------------|-------------|
| <b>Windows 2000</b>                               | Unavailable |
| <b>Windows XP with UMDF version 1.7 and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

[Send comments about this topic to Microsoft](#)

# !wudfext.wudffilehandletarget

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudffilehandletarget** extension displays information about a file-handle-based I/O target.

```
!wudfext.wudffilehandletarget pWDFFileHandleTarget TypeName
```

## Parameters

*pWDFFileHandleTarget*

Specifies the address of the **IWDFIoTarget** interface to display information about. The **!wudfext.wudfobject** extension command determines the address of **IWDFIoTarget**.

*TypeName*

Optional. Specifies the type of the interface (for example, **IWDFDevice**). If a value for *TypeName* is supplied, the extension uses the value as the type of the interface. If an asterisk (\*) is supplied as *TypeName*, or if *TypeName* is omitted, the extension attempts to automatically determine the type of the supplied interface.

## DLL

|                                                   |             |

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfiotarget

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfiotarget** extension displays information about an I/O target including the target's state and list of sent requests.

```
!wudfext.wudfiotarget pWDFTarget TypeName
```

## Parameters

### *pWDFTarget*

Specifies the address of the **IWDFIoTarget** interface to display information about. The **!wudfext.wudfobject** extension command determines the address of **IWDFIoTarget**.

### *TypeName*

Optional. Specifies the type of the interface (for example, **IWDFDevice**). If a value for *TypeName* is supplied, the extension uses the value as the type of the interface. If an asterisk (\*) is supplied as *TypeName*, or if *TypeName* is omitted, the extension attempts to automatically determine the type of the supplied interface.

## DLL

|                                                   |             |

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfobject

5/31/2017 • 3 min to read • [Edit Online](#)

The **!wudfext.wudfobject** extension displays information about a WDF object, as well as its parent and child relationships.

```
!wudfext.wudfobject pWDFObject Flags TypeName
```

## Parameters

### *pWDFObject*

Specifies the address of the WDF interface to display information about.

### *Flags*

Optional. Specifies the type of information to be displayed. *Flags* can be any combination of the following bits. The default value is 0x01.

Bit 0 (0x01)

Steps recursively through the object hierarchy to obtain the parent and child relationships, which are displayed.

Bit 1 (0x02)

Displays only summary information about the object.

Bit 8 (0x80)

Steps recursively through the object hierarchy, and displays details about the internal framework.

### *TypeName*

Optional. Specifies the type of the interface (for example, **IWDFDevice**). If a value for *TypeName* is supplied, the extension uses the value as the type of the interface. If an asterisk (\*) is supplied as *TypeName*, or if *TypeName* is omitted, the extension attempts to automatically determine the type of the supplied interface.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

You can use **!wudfext.wudfobject** to list, for example, the child objects of an **IWDFDevice** object, which generally include the device's queues.

You can also use **!wudfext.wudfobject** to find WDF objects that are associated with a particular device, to check the state of a WDF object (for example, whether the WDF object is in the process of deletion), or to determine the WDF object's current reference count.

The **!wudfext.wudfobject** extension also displays the callback functions and context objects that the driver

associated with each framework object and attempts to determine the framework object's type. This last feature might not work with certain compilers.

The following are some examples. In the first example, **!wudfext.umdevstacks** gives 0x03050E70 as the address of a device object, and this address is then passed to **!wudfext.wudfobject**. The 0x1 flag is included to display all the children of this object.

```

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfrefhist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfrefhist** extension displays the reference count stack history for a UMDF object.

```
!wudfext.wudfrefhist ObjectAddress
```

## Parameters

### *ObjectAddress*

Specifies the address of the UMDF object whose reference count stack history is to be displayed. Note that this is the address of the object itself, not of the interface.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

The **!wudfext.wudfrefhist** command is not supported by UMDF 1.11.

The *ObjectAddress* parameter must be the address of the UMDF object, not the address of the interface (which is used by many other UMDF extension commands). To determine the address of the UMDF object, use the **!wudfext.wudfdumpobjects** command, which displays both the UMDF object address and the interface address. Alternatively, if you know the address of the interface, you can use it as the argument of the **!wudfext.wudfobject** command, which displays the object address (displayed after the symbol "Fx:").

If the reference count tracking option (**TrackRefCount**) has been enabled in WDF Verifier, you can use **!wudfext.wudfrefhist** to display each call stack that increments or decrements an object's reference count. You can determine whether a call stack is causing a memory leak by examining its **AddRef** and **Release** calls for references that are being added and not released.

This command can be used at any time, even if UMDF has not broken in to the debugger.

If this command does not display the desired information, make sure that the relevant data is paged in and then try again.

Here is an example of using the **!wudfext.wudfrefhist** command:

```
0:007> !wudfext.umdevstacks
...
UMDriver Image Path: C:\Windows\System32\drivers\UMDF\WUDFOsrUsbFilter.dll
Object Tracker Address: 0x0000003792ee9fc0
Object Tracking ON
RefCount Tracking ON

0:007> !wudfext.wudfdumpobjects 0x0000003792ee9fc0
...
WdfTypeIoQueue Object: 0x0000003792f05ce0, Interface: 0x0000003792f05d58

0:007> !wudfext.wudfrefhist 0x0000003792f05ce0

# !wudfext.wudfrequest

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfrequest** extension displays information about an I/O request.

```
!wudfext.wudfrequest pWDFRequest
```

## Parameters

*pWDFRequest*

Specifies the address of the **WDFIoRequest** interface to display information about. The **!wudfext.wudfqueue** extension command determines the address of **WDFIoRequest**.

## DLL

|                             |             |
|-----------------------------|-------------|
| <b>Windows 2000</b>         | Unavailable |
| <b>Windows XP and later</b> | Wudfext.dll |

## Additional Information

For more information, see [User-Mode Driver Framework Debugging](#).

## Remarks

The following is an example of the **!wudfext.wudfrequest** display:

```
kd> !wudfrequest 0x000fa530
CWdfIoRequest 0x000fa4b8

# !wudfext.wudfusbinterface

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfusbinterface** extension displays information about a USB interface object.

```
!wudfext.wudfusbinterface pWDFUSBInterface TypeName
```

## Parameters

### *pWDFUSBInterface*

Specifies the address of the **IWDFUsbInterface** interface to display information about. The **!wudfext.wudfobject** extension command determines the address of **IWDFUsbInterface**.

### *TypeName*

Optional. Specifies the type of the interface (for example, **IWDFDevice**). If a value for *TypeName* is supplied, the extension uses the value as the type of the interface. If an asterisk (\*) is supplied as *TypeName*, or if *TypeName* is omitted, the extension attempts to automatically determine the type of the supplied interface.

## DLL

|                                                   |             |

# !wudfext.wudfusbpipe

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfusbpipe** extension displays information about a USB pipe object.

```
!wudfext.wudfusbpipe pWDFUSBPipe TypeName
```

## Parameters

*pWDFUSBPipe*

Specifies the address of the **IWDFUsbTargetPipe** interface to display information about. The **!wudfext.wudfobject** extension command determines the address of **IWDFUsbTargetPipe**.

*TypeName*

Optional. Specifies the type of the interface (for example, **IWDFDevice**). If a value for *TypeName* is supplied, the extension uses the value as the type of the interface. If an asterisk (\*) is supplied as *TypeName*, or if *TypeName* is omitted, the extension attempts to automatically determine the type of the supplied interface.

## DLL

|                                                   |             |

[Send comments about this topic to Microsoft](#)

# !wudfext.wudfusbtarget

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wudfext.wudfusbtarget** extension displays information about a USB I/O target.

```
!wudfext.wudfusbtarget pWDFUSBTarget TypeName
```

## Parameters

*pWDFUSBTarget*

Specifies the address of the **IWDFUsbTargetDevice** interface to display information about. The **!wudfext.wudfobject** extension command determines the address of **IWDFUsbTargetDevice**.

*TypeName*

Optional. Specifies the type of the interface (for example, **IWDFDevice**). If a value for *TypeName* is supplied, the extension uses the value as the type of the interface. If an asterisk (\*) is supplied as *TypeName*, or if *TypeName* is omitted, the extension attempts to automatically determine the type of the supplied interface.

## DLL

[Send comments about this topic to Microsoft](#)

# WMI Tracing Extensions (Wmitrace.dll)

5/26/2017 • 1 min to read • [Edit Online](#)

The extension commands for software tracing sessions can be found in Wmitrace.dll, a library of functions designed to use Windows Management Instrumentation (WMI) for event tracing.

[Send comments about this topic to Microsoft](#)

# !wmitrace.disable

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.disable** extension disables a provider for the specified Event Tracing for Windows (ETW) trace session.

```
!wmitrace.disable { LoggerID | LoggerName } GUID
```

## Parameters

### *LoggerID*

Specifies the trace session. *LoggerID* is an ordinal number that the system assigns to each trace session on the computer.

### *LoggerName*

Specifies the trace session. *LoggerName* is the text name that was specified when the trace session was started.

### *GUID*

Specifies the GUID of the provider to be disabled.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 7 and later versions of Windows.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

## Remarks

After using this extension, you must resume program execution (for example, by using the **g (Go)** command) in order for it to take effect. After a brief time, the target computer automatically breaks into the debugger again.

To enable a provider, use **!wmitrace.enable**.

[Send comments about this topic to Microsoft](#)

# !wmitrace.dumpmini

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.dumpmini** extension displays the system trace fragment, which is stored in a dump file.

```
!wmitrace.dumpmini
```

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows Vista and later versions of Windows.

This extension is useful only when debugging a minidump file or a full dump file.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

## Remarks

The *system trace fragment* is a copy of the contents of the last buffer of the System Context Log. Under normal conditions, this is the trace session whose logger ID is 2.

[Send comments about this topic to Microsoft](#)

# !wmitrace.dumpminievent

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.dumpminievent** extension displays the system event log trace fragment, which is stored in a dump file.

```
!wmitrace.dumpminievent
```

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows Vista Service Pack 1 (SP1) and later versions of Windows.

This extension is useful only when debugging a minidump file or a full dump file.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

## Remarks

The *system event log trace fragment* is a copy of the contents of the last buffer of the System Event Log. The **!wmitrace.dumpminievent** extension displays its contents in event log format.

[Send comments about this topic to Microsoft](#)

# !wmitrace.dynamicprint

5/31/2017 • 2 min to read • [Edit Online](#)

The **!wmitrace.dynamicprint** extension controls whether the debugger displays the trace messages generated by a session running in KD\_FILTER\_MODE.

```
!wmitrace.dynamicprint {0 | 1}
```

## Parameters

**0**

Turns the trace message display off.

**1**

Turns the trace message display on.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For help in starting a trace session, see "Tracelog" in the Windows Driver Kit (WDK).

## Remarks

Before you use this extension, start a trace session, and specify that the trace messages should be sent to the debugger. For example, if you use **!wmitrace.start** to start the session, use the **-kd** parameter. If you use Tracelog to start the trace session, use its **-kd** parameter. Tracelog (tracelog.exe) is a trace controller included in the Windows Driver Kit.

Trace messages are held in a buffers on the target computer. Those buffers are flushed and sent to the debugger on the host computer at regular intervals. You can specify the flush timer interval by using the **-kd** parameter of the **!wmitrace.start** command or the **-kd** parameter of the Tracelog tool. Starting in Windows 8, you can specify the flush timer value in milliseconds by appending **ms** to the flush timer value.

By default, ETW maintains per-processor trace buffers on the target computer. When the trace buffers are flushed and sent to the debugger on the host computer, there is no mechanism for merging the buffers into a chronological sequence of events. So the events might be displayed out of order. Starting in Windows 7, you can solve this problem by setting the **-lowcapacity** parameter when you use the Tracelog tool to start a trace session.

### **Tracelog MySession -kd -lowcapacity**

When you start a session with **-lowcapacity** set, all events go to a single buffer on the target computer, and the events are displayed in the correct order in the debugger on the host computer.

Also, before using this extension, use **!wmitrace.searchpath** or **!wmitrace.tmffile** to specify the trace message format files. The system uses the trace message format files to format the binary trace messages so that they can

be displayed as human-readable text.

## See also

**[!wmitrace.start](#)**

[Send comments about this topic to Microsoft](#)

# !wmitrace.enable

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.enable** extension enables a provider for the specified Event Tracing for Windows (ETW) trace session.

```
!wmitrace.enable { LoggerID | LoggerName } GUID [-level Num] [-matchallkw Num] [-matchanykw Num] [-enableproperty Num] [-flag Num]
```

## Parameters

### *LoggerID*

Specifies the trace session. *LoggerID* is an ordinal number that the system assigns to each trace session on the computer.

### *LoggerName*

Specifies the trace session. *LoggerName* is the text name that was specified when the trace session was started.

### *GUID*

Specifies the GUID of the provider to be enabled.

### **-level** *Num*

Specifies the level. *Num* can be any integer.

### **-matchallkw** *Num*

Specifies one or more keywords. If multiple keywords are specified, the provider will be enabled only if all keywords are matched. *Num* can be any integer.

### **-matchanykw** *Num*

Specifies one or more keywords. If multiple keywords are specified, the provider will be enabled if at least one keyword is matched. *Num* can be any integer. The effects of this parameter overlap with the effects of the **-flag** parameter.

### **-enableproperty** *Num*

Specifies the enable property. *Num* can be any integer.

### **-flag** *Num*

Specifies one or more flags. *Num* can be any integer. The effects of this parameter overlap with the effects of the **-matchanykw** parameter.

## **DLL**

This extension is exported by Wmitrace.dll.

This extension is available in Windows 7 and later versions of Windows.

## **Additional Information**

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

## Remarks

After using this extension, you must resume program execution (for example, by using the **g (Go)** command) in

order for it to take effect. After a brief time, the target computer automatically breaks into the debugger again.

To disable a provider, use **[!wmitrace.disable](#)**.

[Send comments about this topic to Microsoft](#)

# !wmitrace.eventlogdump

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.eventlogdump** extension displays the contents of the specified logger. The display is formatted like an event log.

```
!wmitrace.eventlogdump { LoggerID | LoggerName }
```

## Parameters

### *LoggerID*

Specifies the trace session. *LoggerID* is an ordinal number that the system assigns to each trace session on the computer.

### *LoggerName*

Specifies the trace session. *LoggerName* is the text name that was specified when the trace session was started.

### **DLL**

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

### **Additional Information**

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

## Remarks

This extension is similar to the [!wmitrace.logdump](#) extension, except that the output of **!wmitrace.eventlogdump** is formatted in event log style, and the output of [!wmitrace.logdump](#) is formatted in Windows software trace preprocessor (WPP) style. You should choose the extension whose format is appropriate for the data you wish to display.

To find the logger ID of a trace session, use the [!wmitrace.strdump](#) extension. Alternatively, you can use the Tracelog command tracelog -l to list the trace sessions and their basic properties, including the logger ID.

[Send comments about this topic to Microsoft](#)

# !wmitrace.help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.help** extension displays the extension commands in Wmitrace.dll.

```
!wmitrace.help
```

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

[Send comments about this topic to Microsoft](#)

# !wmitrace.logdump

5/31/2017 • 2 min to read • [Edit Online](#)

The **!wmitrace.logdump** extension displays the contents of the trace buffers for a trace session. You can limit the display to trace messages from specified providers.

```
!wmitrace.logdump [-t Count] [{LoggerID|LoggerName} [GUIDFile]]
```

## Parameters

### **-t Count**

Limits the output to the most recent messages. *Count* specifies the number of messages to display.

### *LoggerID*

Specifies the trace session. *LoggerID* is an ordinal number that the system assigns to each trace session on the computer. If no parameter is specified, the trace session with ID equal to 1 is used.

### *LoggerName*

Specifies the trace session. *LoggerName* is the text name that was specified when the trace session was started.

### *GUIDFile*

Displays only trace messages from providers specified in the *GUIDFile* file. *GUIDFile* represents the path (optional) and file name of a text file that contains the control GUIDs of one or more trace providers, such as a .guid or .ctl file.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about Tracelog, see "Tracelog" in the Windows Driver Kit (WDK).

## Remarks

During Windows software trace preprocessor (WPP) software tracing, trace session buffers are used to store trace messages until they are flushed to a log file or to a trace consumer for a real-time display. The

**!wmitrace.logdump** extension displays the contents of the buffers that are in physical memory. The display appears in the Debugger Command window.

This extension is especially useful to recover the most recent traces when a crash occurs, and to display the traces stored in a crash dump file.

Before you use this extension, use **!wmitrace.searchpath** or **!wmitrace.tmffile** to specify the trace message format files. The system uses the trace message format files to format the binary trace messages in the buffers so that they can be displayed as human-readable text.

**Note** If your driver uses UMDF version 1.11 or later, you do not need to use **!wmitrace.searchpath** or **!wmitrace.tmffile**.

When you use Tracelog to start a trace session with circular buffering (-buffering), use this extension to display the buffer contents.

To find the logger ID of a trace session, use the **!wmitrace.strdump** extension. Alternatively, you can use the Tracelog command tracelog -l to list the trace sessions and their basic properties, including the logger ID.

This extension is only useful during WPP software tracing, and earlier (legacy) methods of Event Tracing for Windows. Trace events that are produced by other manifested providers do not use trace message format (TMF) files, and therefore this extension does not display their contents.

This extension is similar to the **!wmitrace.eventlogdump** extension, except that the output of **!wmitrace.logdump** is formatted in WPP style, and the output of **!wmitrace.eventlogdump** is formatted in event log style. You should choose the extension whose format is appropriate for the data you want to display.

For information about how to view the UMDF trace log, see [Using WPP Software Tracing in UMDF-based Drivers](#).

[Send comments about this topic to Microsoft](#)

# !wmitrace.logger

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.logger** extension displays data about the trace session, including the session configuration data. This extension does not display trace messages generated during the session.

```
!wmitrace.logger [LoggerID | LoggerName]
```

## Parameters

### *LoggerID*

Specifies the trace session. *LoggerID* is an ordinal number that the system assigns to each trace session on the computer. If no parameter is specified, the trace session with ID equal to 1 is used.

### *LoggerName*

Specifies the trace session. *LoggerName* is the text name that was specified when the trace session was started.

### **DLL**

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

### **Additional Information**

For a conceptual overview of event tracing, see the Microsoft Windows SDK.

## Remarks

This extension is designed for performance logs and events, which cannot be formatted for human-readable display. To display the trace messages in a trace session buffer, along with header data, use [!wmitrace.logdump](#).

To find the logger ID of a trace session, use the [!wmitrace.strdump](#) extension. Alternatively, you can use the Tracelog command tracelog -l to list the trace sessions and their basic properties, including the logger ID.

[Send comments about this topic to Microsoft](#)

# !wmitrace.logsav

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.logsav** extension writes the current contents of the trace buffers for a trace session to a file.

```
!wmitrace.logsav {LoggerID|LoggerName} Filename
```

## Parameters

### *LoggerID*

Specifies the trace session. *LoggerID* is an ordinal number that the system assigns to each trace session on the computer.

### *LoggerName*

Specifies the trace session. *LoggerName* is the text name that was specified when the trace session was started.

### *Filename*

Specifies a path (optional) and file name for the output file.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about Tracelog, see "Tracelog" in the Windows Driver Kit (WDK).

## Remarks

This extension displays only the traces that are in memory at the time. It does not display trace messages that have been flushed from the buffers and delivered to an event trace log file or to a trace consumer.

Trace session buffers store trace messages until they are flushed to a log file or to a trace consumer for a real-time display. This extension saves the contents of the buffers that are in physical memory to the specified file.

The output is written in binary format. Typically, these files use the .etl (event trace log) filename extension.

When you use Tracelog to start a trace session with circular buffering (-buffering), you can use this extension to save the current buffer contents.

To find the logger ID of a trace session, use the [!wmitrace.strdump](#) extension. Alternatively, you can use the Tracelog command tracelog -l to list the trace sessions and their basic properties, including the logger ID.

[Send comments about this topic to Microsoft](#)

# !wmitrace.searchpath

5/31/2017 • 2 min to read • [Edit Online](#)

The **!wmitrace.searchpath** extension specifies the location of the trace message format files for messages in the trace buffers.

```
!wmitrace.searchpath [+]
!wmitrace.searchpath
```

## Parameters

**+**

Causes *TMFPath* to be appended to the existing search path. If the plus (+) token is not used, *TMFPath* replaces the existing search path.

*TMFPath*

The path to the directory where the debugger should look for the trace message format files. Paths that contain spaces are not supported. If multiple paths are included, they should be separated by semicolons, and the entire string should be enclosed in quotation marks. If the path is in quotation marks, the backslash character must be preceded by an escape character ( "c:\\debuggers;c:\\debuggers2" ). When the + token is used, *TMFPath* will be appended to the existing path, with a semicolon automatically inserted between the existing path and the new path; however, if the + token is used, quotation marks cannot be used.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about trace message format files, see the "Trace Message Format Files" topic in the Windows Driver Kit (WDK).

## Remarks

When used with no parameters, **!wmitrace.searchpath** displays the current search path.

The trace message format files (\*.tmf) contain instructions for formatting the binary trace messages that a trace provider generates.

The *TMFPath* parameter must contain only a path to a directory; it cannot include a file name. The name of a TMF file is a message GUID followed by the .tmf extension. When the system formats a message, it reads the message GUID on the message and searches recursively for a TMF file whose name matches the message GUID, beginning in the specified directory.

Windows needs a TMF file in order to format the binary trace messages in a buffer. Use **!wmitrace.searchpath** or **!wmitrace.tmffile** to specify the TMF file before using **!wmitrace.dynamicprint** or **!wmitrace.logdump** to display trace buffer contents.

If you do not use either **!wmitrace.searchpath** or **!wmitrace.tmffile**, the system uses the value of the

TRACE\_FORMAT\_SEARCH\_PATH environment variable. If that variable is not present, it uses the default.tmf file, which is included in Windows. If the system cannot find any formatting information for a trace message, it writes a "No format information found" error message in place of the trace message content.

[Send comments about this topic to Microsoft](#)

# !wmitrace.setprefix

5/31/2017 • 4 min to read • [Edit Online](#)

The **!wmitrace.setprefix** extension specifies the trace message prefix that is prepended to the trace messages from this session. This extension allows you to change the prefix during the debugging session.

```
!wmitrace.setprefix [+]
!wmitrace.setprefix
```

## Parameters

+

Causes *PrefixVariables* to be appended to the trace message prefix. If the + token is not used, *PrefixVariables* replaces the existing trace message prefix.

### *PrefixVariables*

A set of variables that specifies the format and data in the trace message prefix.

The variables have the format %n!x!, where %n represents a data field and !x! represents the data type. You can also include separation characters, such as colons (:), semicolons (;), parentheses ( () ), braces ( { } ), and brackets ( [ ] ) to separate the fields.

Each %n variable represents a parameter that is described in the following table.

| PREFIX VARIABLE IDENTIFIER | VARIABLE TYPE | DESCRIPTION                                                                                                                                                                                                                                     |
|----------------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %1                         | string        | The friendly name of the message GUID of the trace message. By default, the friendly name of a message GUID is the name of the directory in which the trace provider was built.                                                                 |
| %2                         | string        | Source file and line number. This variable represents the friendly name of the trace message. By default, the friendly name of a trace message is the name of the source file and the line number of the code that generated the trace message. |
| %3                         | ULONG         | Thread ID. Identifies the thread that generated the trace message.                                                                                                                                                                              |
| %4                         | string        | Time stamp of the time that the trace message was generated.                                                                                                                                                                                    |

| PREFIX VARIABLE IDENTIFIER | VARIABLE TYPE | DESCRIPTION                                                                                                                                                                                |
|----------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %5                         | string        | <p>Kernel time.</p> <p>Displays the elapsed execution time for kernel-mode instruction, in CPU ticks, at the time that the trace message was generated.</p>                                |
| %6                         | string        | <p>User time.</p> <p>Displays the elapsed execution time for user-mode instruction, in CPU ticks, at the time that the trace message was generated.</p>                                    |
| %7                         | LONG          | <p>Sequence number.</p> <p>Displays the local or global sequence number of the trace message. Local sequence numbers, which are unique only to this trace session, are the default.</p>    |
| %8                         | ULONG         | <p>Process ID.</p> <p>Identifies the process that generated the trace message.</p>                                                                                                         |
| %9                         | ULONG         | <p>CPU number.</p> <p>Identifies the CPU on which the trace message was generated.</p>                                                                                                     |
| %!FUNC!                    | string        | <p>Function name.</p> <p>Displays the name of the function that generated the trace message.</p>                                                                                           |
| %!FLAGS%                   | string        | Displays the name of the trace flags that enable the trace message.                                                                                                                        |
| %!LEVEL!                   | string        | Displays the value of the trace level that enables the trace message.                                                                                                                      |
| %!COMPNAME!                | string        | <p>Component name.</p> <p>Displays the name of the component of the provider that generated the trace message. The component name appears only if it is specified in the tracing code.</p> |

| PREFIX VARIABLE IDENTIFIER | VARIABLE TYPE | DESCRIPTION                                                                                                                                                                                         |
|----------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %!SUBCOMP!                 | string        | <p>Subcomponent name.</p> <p>Displays the name of the subcomponent of the provider that generated the trace message. The subcomponent name appears only if it is specified in the tracing code.</p> |

The symbol within exclamation marks is a conversion character that specifies the format and precision of the variable. For example, %8!04X! specifies the process ID formatted as a four-digit, unsigned, hexadecimal number.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

## Example

The following command changes the trace message prefix in the debugger output to the following format:

**!wmitrace.setprefix %2!s!: %!FUNC!: %8!04x!.%3!04x!: %4!s!:**

This extension command sets the trace message prefix to the following format:

*SourceFileLineNumber: FunctionName: ProcessID. ThreadID: SystemTime:*

As a result, the trace messages are prepended with the specified information in the specified format. The following code example is taken from a trace of the Tracedrv sample driver in the WDK.

```
tracedrv_c258: TracedrvDispatchDeviceControl: 0af4.0c64: 07/25/2003-13:55:39.998: IOCTL = 1
```

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK documentation. For information about trace message format files, see the "Trace Message Prefix" topic in the WDK documentation.

## Remarks

When used with no parameters, **!wmitrace.setprefix** displays the current value of the trace message prefix.

The *trace message prefix* consists of data about the trace message that is prepended to each trace message during Windows software trace preprocessor (WPP) software tracing. This data originates in the trace log (.etl) file and the trace message format (.tmf) file. You can customize the format and data in trace message prefix.

The default trace message prefix is as follows:

```
[%9!d!]%8!04X!.%3!04X!::%4!s! [%1!s!]
```

and produces the following prefix:

```
[CPUNumber]ProcessID. ThreadID::SystemTime [ProviderDirectory]
```

You can change the format and data in the trace message prefix outside of the debugger by setting the

%TRACE\_FORMAT\_PREFIX% environment variable. For an example that illustrates how to set the trace message prefix outside of the debugger, see "Example 7: Customizing the Trace Message Prefix" in the Windows Driver Kit (WDK) documentation. If the trace message prefix of your messages varies from the default, this environment variable might be set on your computer.

The prefix that you set by using this extension command affects only the debugger output. The trace message prefix that appears in the trace log is determined by the default value and the value of the %TRACE\_FORMAT\_PREFIX% environment variable.

This extension is only useful during WPP software tracing, and earlier (legacy) methods of Event Tracing for Windows. Trace events that are produced by other manifested providers do not use trace message format (TMF) files, and therefore this extension does not affect them.

[Send comments about this topic to Microsoft](#)

# !wmitrace.start

5/31/2017 • 2 min to read • [Edit Online](#)

The **!wmitrace.start** extension starts the Event Tracing for Windows (ETW) logger on the target computer.

```
!wmitrace.start LoggerName [-cir Size | -seq Size] [-f File] [-b Size] [-max Num] [-min Num] [-kd] [-ft Time]
```

## Parameters

### *LoggerName*

Supplies a name to be used for the trace session. *LoggerName* cannot contain spaces or quotation marks.

### **-cir** *Size*

Causes the log file to be written in a circular manner. *Size* specifies the maximum file size, in bytes. When the file reaches this length, new data will be written to the file in a circular manner, overwriting the file from beginning to end. This cannot be combined with the **-seq** parameter. If neither **-cir** nor **-seq** is specified, the file is written in buffered mode.

### **-seq** *Num*

Causes the log file to be written in a sequential manner. *Size* specifies the maximum file size, in bytes. When the file reaches this length, the oldest data will be deleted from the beginning of the file whenever new data is appended to the end. This cannot be combined with the **-cir** parameter. If neither **-cir** nor **-seq** is specified, the file is written in buffered mode.

### **-f** *File*

Specifies the name of the log file to be created on the target computer. *File* must include an absolute directory path, and cannot contain spaces or quotation marks.

### **-b** *Size*

Specifies the size of each buffer, in kilobytes. The permissible range of *Size* is between 1 and 2048, inclusive.

### **-max** *Num*

Specifies the maximum number of buffers to use. *Num* can be any positive integer.

### **-min** *Num*

Specifies the minimum number of buffers to use. *Num* can be any positive integer.

### **-kd**

Enables KD filter mode. Messages will be sent to the kernel debugger and displayed on the screen.

### **-ft** *Time*

Specifies the duration of the flush timer, in seconds. Starting in Windows 8, you can specify the flush timer duration in milliseconds by appending **ms** to the *Time* value. For example, **-ft 100ms**.

**Note** If you start a tracing session in KD filter mode (**-kd**), trace buffers on the target computer are sent to the debugger on the host computer for display. This parameter specifies how often the buffers on the target computer are flushed and sent to the host computer.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 7 and later versions of Windows.

## Additional Information

For more details on the parameters of this extension, see [StartTrace Function](#) and [EVENT\\_TRACE\\_PROPERTIES](#) on MSDN. For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

## Remarks

After using this extension, you must resume program execution (for example, by using the **g (Go)** command) in order for it to take effect. After a brief time, the target computer automatically breaks into the debugger again.

When the trace session is started, the system assigns it an ordinal number (the *logger ID*). The session can then be referred to either by the logger name or the logger ID.

To stop the ETW logger, use [!wmitrace.stop](#).

[Send comments about this topic to Microsoft](#)

# !wmitrace.stop

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.stop** extension stops the Event Tracing for Windows (ETW) logger on the target computer.

```
!wmitrace.stop { LoggerID | LoggerName }
```

## Parameters

### *LoggerID*

Specifies the trace session. *LoggerID* is an ordinal number that the system assigns to each trace session on the computer.

### *LoggerName*

Specifies the trace session. *LoggerName* is the text name that was specified when the trace session was started.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 7 and later versions of Windows.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about tracing tools, see the Windows Driver Kit (WDK).

## Remarks

After using this extension, you must resume program execution (for example, by using the **g (Go)** command) in order for it to take effect. After a brief time, the target computer automatically breaks into the debugger again.

To start the ETW logger, use **!wmitrace.start**.

[Send comments about this topic to Microsoft](#)

# !wmitrace.strdump

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.strdump** extension displays the WMI event trace structures. You can limit the display to the structures for a particular trace session.

```
!wmitrace.strdump [LoggerID | LoggerName]
```

## Parameters

### *LoggerID*

Limits the display to the event trace structures for the specified trace session. *LoggerID* specifies the trace session. It is an ordinal number that the system assigns to each trace session on the computer. If no parameter is specified, all trace sessions are displayed.

### *LoggerName*

Limits the display to the event trace structures for the specified trace session. *LoggerName* is the text name that was specified when the trace session was started. If no parameter is specified, all trace sessions are displayed.

### **DLL**

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

### **Additional Information**

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about Tracelog, see the "Tracelog" topic in the Windows Driver Kit (WDK).

## Remarks

To find the logger ID of a trace session, use the **!wmitrace.strdump** extension. Alternatively, you can use the Tracelog command tracelog -l to list the trace sessions and their basic properties, including the logger ID.

[Send comments about this topic to Microsoft](#)

# !wmitrace.tfp

5/26/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.tfp** extension command is obsolete. Use **!wmitrace.setprefix** instead.

[Send comments about this topic to Microsoft](#)

# !wmitrace.tmffile

5/31/2017 • 2 min to read • [Edit Online](#)

The **!wmitrace.tmffile** extension specifies a trace message format (TMF) file. The file specified by this extension is used to format trace messages displayed or written by other WMI tracing extensions.

```
!wmitrace.tmffile TMFFile
```

## Parameters

### *TMFFile*

Specifies a trace message format file.

### **DLL**

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

### Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK. For information about trace message format files, see the "Trace Message Format File" topic in the Windows Driver Kit (WDK).

## Remarks

*Trace message format files* (.tmf) are structured text files that are created during Windows software trace preprocessor (WPP) software tracing. These files contain instructions for formatting trace binary trace messages so that they can be displayed in human-readable form.

In order to display the trace message in a trace buffer (**!wmitrace.logdump**) or write them to a file (**!wmitrace.logsave**), you must first identify the TMF files for the trace messages.

You can use **!wmitrace.searchpath** to specify a directory in which TMF files are stored. The system then searches the directory for a TMF file that contains instructions for the messages that it is formatting. (It uses the message GUID to associate the message with the correct TMF file.)

However, you can use **!wmitrace.tmffile** to specify a particular TMF file. You must use **!wmitrace.tmffile** if the TMF file name is not a message GUID followed by the .tmf extension. Otherwise, the system will not find it.

If you do not use either **!wmitrace.searchpath** or **!wmitrace.tmffile**, the system uses the value of the TRACE\_FORMAT\_SEARCH\_PATH environment variable. If that variable is not present, it uses the default.tmf file. If the system cannot find formatting information for a trace message, it writes a "No format information found" error message, instead of the trace message content.

**Note** If your driver uses UMDF version 1.11 or later, you do not need to use **!wmitrace.searchpath** or **!wmitrace.tmffile**.

This extension is only useful during WPP software tracing, and earlier (legacy) methods of Event Tracing for Windows. Trace events that are produced by other manifested providers do not use trace message format (TMF) files, and therefore this extension cannot be used with them.

[Send comments about this topic to Microsoft](#)

# !wmitrace.traceoperation

5/31/2017 • 1 min to read • [Edit Online](#)

The **!wmitrace.traceoperation** extension displays the progress messages from the tracing components in Windows.

```
!wmitrace.traceoperation {0 | 1 | 2}
```

## Parameters

**0**

Disables the display of tracing progress messages.

**1**

Enables the display of tracing progress messages. All messages generated by the WMI tracing debugger extensions are displayed.

**2**

Enables the display of tracing progress messages. All messages generated by the WMI tracing debugger extensions or by Tracefmt are displayed.

## DLL

This extension is exported by Wmitrace.dll.

This extension is available in Windows 2000 and later versions of Windows. If you want to use this extension with Windows 2000, you must first copy the Wmitrace.dll file from the winxp subdirectory of the Debugging Tools for Windows installation directory to the w2kfre subdirectory.

## Additional Information

For a conceptual overview of event tracing, see the Microsoft Windows SDK.

## Remarks

This extension causes the tracing components to display verbose output. This feature is useful to troubleshoot software tracing.

# Debugger Error and Warning Messages

5/26/2017 • 1 min to read • [Edit Online](#)

This reference section describes some of the error and warning messages that the debugger can display.

[Send comments about this topic to Microsoft](#)

# dbgerr001: PEB is Paged Out

5/26/2017 • 1 min to read • [Edit Online](#)

Debugger error **dbgerr001** displays the message "PEB is paged out." This error indicates that the process environment block (PEB) is not accessible.

To load symbols, the debugger looks at the list of modules loaded by the operating system. The pointer to the user-mode module list is one of the items stored in the PEB.

In order to reclaim memory, the Memory Manager may page out user-mode data to make space for other process or kernel mode components.

When this error occurs, it means that the debugger has detected that the PEB data structure for this process is no longer readable. Most likely, it has been paged out to disk.

Without this data structure, the debugger cannot determine what images the symbols should be loaded for.

**Note** This only affects symbol files for the user-mode modules. Kernel-mode modules and symbols are not affected, as they are tracked in a different list.

[Send comments about this topic to Microsoft](#)

# dbgerr002: Bad Pointer

5/26/2017 • 1 min to read • [Edit Online](#)

Debugger error **dbgerr002** displays the message "Bad pointer." This error indicates a problem retrieving a symbol file.

The symbol server has the file indexed, but is being redirected to another location to find the file. No file is accessible at this other location.

Two common causes of this problem are:

- The path is a UNC path, and the computer containing this server is not available.
- The path indicates a directory or file that has been deleted.

If your symbol store was created by using SymStore, you can find the full path to this file by examining file.ptr. For details, see [Using SymStore](#).

[Send comments about this topic to Microsoft](#)

# dbgerr003: Mismatched Symbols

5/26/2017 • 1 min to read • [Edit Online](#)

Debugger error **dbgerr003** displays the message "*File* has mismatched symbols." This error indicates that DbgHelp found the symbol file represented by *File*, but that the symbol file is not the correct version, or that DbgHelp cannot confirm that the symbol file is the correct version.

The debugger might load the specified symbol file despite this error, depending on other requirements in the path.

[Send comments about this topic to Microsoft](#)

# dbgerr004: Page Not Present in Dump File

5/26/2017 • 1 min to read • [Edit Online](#)

Debugger error **dbgerr004** displays the message "Page *number* not present in dump file." This error indicates that the debugger needed a memory page that was not included in the dump file being debugged.

The specified *number* is the page frame number (PFN) corresponding to the location in the physical memory of the original page.

To suppress this error message, use the [.ignore\\_missing\\_pages 1](#) command. This command allows debugging to proceed, but does not display this error message.

Kernel-mode memory dumps come in three sizes, and the smaller sizes do not include all the memory pages. For details, see [Varieties of Kernel-Mode Dump Files](#).

User-mode memory dumps also come in various sizes. See [User-Mode Dump Files](#) for details.

[Send comments about this topic to Microsoft](#)

# dbgerr005: Private Symbols Required

5/26/2017 • 1 min to read • [Edit Online](#)

Debugger error **dbgerr005** displays the message "Private symbols (symbols.pri) are required for locals." This error indicates that the debugger is unable to perform an action because private symbols are not present.

During kernel-mode debugging, the debugger needs symbols for Microsoft Windows. During user-mode debugging, the debugger needs symbols for the target application, and often needs symbols for Windows as well.

Some basic symbols, such as function names and global variables, are needed for even the most rudimentary debugging. These are called *public symbols*. Symbols such as data structure names, global variables visible in only one object file, local variables, and line number information are not always required for debugging, although they are useful for a more in-depth debugging session. These are called *private symbols*.

Many software manufacturers, including Microsoft, produce two versions of their symbol files. The version released to their customers contains only public symbols. The version used internally contains both public and private symbols.

Most debugging actions can be performed with public symbols alone. But certain actions -- such as displaying local variables -- require private symbols. When an action of this sort is attempted and private symbols are not available, this error message is displayed.

When you see this message, it is usually best to simply continue debugging. The information you were unable to obtain is probably not essential to properly debugging the target.

# Stack Unwind Information Not Available

5/26/2017 • 1 min to read • [Edit Online](#)

When the debugger is examining the call stack, it may display the message "Stack unwind information not available. Following frames may be wrong."

This warning indicates that the debugger is not certain that the frames in the call stack listed after this message are correct.

To trace the call stack, the debugger examines the stack and analyzes the functions that have used the stack. This lets it identify the chain of return addresses that form the call stack. However, this procedure requires symbol information for each module containing the functions that used the stack.

If this symbol information is not available, the debugger is forced to make a best guess about which frames are return addresses. This warning information is displayed to indicate the uncertain nature of the call stack after this point.

[Send comments about this topic to Microsoft](#)

# No Header Information Available

5/26/2017 • 1 min to read • [Edit Online](#)

The debugger identifies the proper symbols by examining the headers of the relevant modules. If these module headers are paged out, the debugger (and the symbol server) are unable to find the proper symbols. When this occurs, "No Header Information Available" is displayed within the symbol error message.

For information about how to debug a target when module headers are paged out, see [Reading Symbols from Paged-Out Headers](#).

# WinDbg Graphical Interface Features

5/26/2017 • 1 min to read • [Edit Online](#)

This section discusses the elements of the WinDbg graphical user interface. These elements include the following:

[File Menu](#)

[Edit Menu](#)

[View Menu](#)

[Debug Menu](#)

[Window Menu](#)

[Help Menu](#)

[Toolbar Buttons](#)

[Shortcut Keys](#)

[Send comments about this topic to Microsoft](#)

# File Menu

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the following commands on the **File** menu of WinDbg:

[File | Open Source File](#)

[File | Close Current Window](#)

[File | Open Executable](#)

[File | Attach to a Process](#)

[File | Open Crash Dump](#)

[File | Connect to Remote Session](#)

[File | Connect to Remote Stub](#)

[File | Kernel Debug](#)

[File | Symbol File Path](#)

[File | Source File Path](#)

[File | Image File Path](#)

[File | Open Workspace](#)

[File | Save Workspace](#)

[File | Save Workspace As](#)

[File | Clear Workspace](#)

[File | Delete Workspaces](#)

[File | Open Workspace in File](#)

[File | Save Workspace to File](#)

[File | Map Network Drive](#)

[File | Disconnect Network Drive](#)

[File | Recent Files](#)

[File | Exit](#)

[Send comments about this topic to Microsoft](#)

# File | Open Source File

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Open Source File** on the **File** menu to load a specific source file.

This command is equivalent to pressing CTRL+O or clicking the **Open source file (Ctrl+O)** button (

## Dialog Box

When you click **Open Source File**, the **Open Source File** dialog box appears. To open a file, do the following:

1. In the **Look in** list, select the directory where the file is located. The directory last opened is selected by default.
2. In the **Files of type** list, select the type of file that you want to open. Only files with the chosen extensions are displayed in the **Open Source File** dialog box. **Note** You can also use wildcard patterns in the **File name** box to display only files with a certain extension. The new wildcard pattern is retained in a session until you change it. You can use any combination of wildcard patterns, separated by semicolons. For example, entering **\*.INC; \*.H; \*.CPP** displays all files with these extensions. The maximum number of characters in a line is 251.
3. If you find the file you want, double-click the file name, or click the file name and click **Open**.

-OR-

To discard changes and close the dialog box, click **Cancel**.

The names of the four files that you opened most recently in WinDbg are displayed when you point to **Recent files** on the **File** menu. To open one of these files, click its name.

## Additional Information

For more information about source files and source paths and for other ways to load source files, see [Source Path](#).

[Send comments about this topic to Microsoft](#)

# File | Close Current Window

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Close Current Window** on the **File** menu to close the active debugging information window.

This command is equivalent to pressing CTRL+F4.

You can also close a debugging information window by clicking the **Close** button in the upper-right corner of the information window inside the WinDbg window.

[Send comments about this topic to Microsoft](#)

# File | Open Executable

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Open Executable** on the **File** menu to start a new user-mode process and debug it.

This command is equivalent to pressing CTRL+E. You can use this command only when WinDbg is in dormant mode.

## Dialog Box

When you click **Open Executable**, the **Open Executable** dialog box appears, and you can do the following:

- Enter the full path of the executable file in the **File name** box. Alternatively, you can use the dialog box to locate and select the proper file. You must specify the exact path to the executable file. Unlike the Microsoft Windows **Run** dialog box and a Command Prompt window, the **Open Executable** dialog box does not search the current path for an executable name.
- If you want to use command-line arguments with the executable file, enter them in the **Arguments** box.
- If you want to change the starting directory from the default directory enter the directory path in the **Start directory** box.
- If you want WinDbg to attach to any *child processes* (additional processes that the original target process started), select **Debug child processes also**.

After you make your selections, click **Open**.

**Note** When you use this command to open a source file, the path to that file is automatically appended to the [source path](#).

If WinDbg is connected to a process server, you cannot use the **Open Executable** command.

## Additional Information

For more information and other methods of starting new processes for debugging, see [Debugging a User-Mode Process Using WinDbg](#).

[Send comments about this topic to Microsoft](#)

# File | Attach to a Process

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Attach to a Process** on the **File** menu to debug a user-mode application that is currently running.

This command is equivalent to pressing F6. You can use this command only when WinDbg is in dormant mode.

## Dialog Box

When you click **Attach to a Process**, the **Attach to Process** dialog box appears, and you can do the following:

- Select the line that contains the proper process ID and name (or enter the process ID in the **Process ID** box).  
**Note** Each listed process has an associated plus sign (+). You can click the plus sign to display information about that process' command line, services, and child processes.

**\*\*Note\*\*** If WinDbg is connected to a process server, the **Attach to Process** dialog box will display processes that are running on the remote computer. For more information about process servers, see [\[\\*\\*Activating a Smart Client\\*\\*\]\(activating-a-smart-client.md\)](#).

- If you want to attach noninvasively to a process, select the **Noninvasive** check box.

After you make your selections, click **OK**.

## Additional Information

For more information and other methods of attaching to a process, see [Debugging a User-Mode Process Using WinDbg](#) and [Noninvasive Debugging \(User Mode\)](#).

[Send comments about this topic to Microsoft](#)

# File | Open Crash Dump

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Open Crash Dump** on the **File** menu to open a user-mode or kernel-mode crash dump file and to analyze it.

This command is equivalent to pressing CTRL+D. You can use this command only when WinDbg is in dormant mode.

## Dialog Box

When you click **Open Crash Dump**, the **Open Crash Dump** dialog box appears. Enter the full path of the crash dump file in the **File name** box, or use the **Look in** list to find and select the proper path and file name. (Dump files typically end with the .dmp or .mdmp extension.)

After you choose the proper file, click **Open**.

## Additional Information

For more information about analyzing crash dump files, see [Analyzing a User-Mode Dump File with WinDbg](#) or [Analyzing a Kernel-Mode Dump File with WinDbg](#).

[Send comments about this topic to Microsoft](#)

# File | Connect to Remote Session

5/31/2017 • 3 min to read • [Edit Online](#)

Click **Connect to Remote Session** on the **File** menu to make WinDbg a debugging client and to connect to an active debugging server.

This command is equivalent to pressing CTRL+R. You can use this command only when WinDbg is in dormant mode.

You cannot use this command to connect to a process server or a KD connection server; for that purpose, use [File | Connect to Remote Stub](#) instead.

## Connect to Remote Debugger Session Dialog Box

When you click **Connect to Remote Session**, the **Connect to Remote Debugger Session** dialog box appears. You can use this dialog box to enter the remote connection parameters or to browse a list of debugging servers.

To manually specify the remote connection parameters, enter one of the following strings in the **Connection string** box:

```
npipe:server=Server,pipe=PipeName[,password=Password]
tcp:server=Server,port=Socket[,password=Password][,ipversion=6]
tcp:clicon=Server,port=Socket[,password=Password][,ipversion=6]
com:port=COMPort,baud=BaudRate,channel=COMChannel[,password=Password]
spipe:proto=Protocol,{certuser=Cert|machuser=Cert},server=Server,pipe=PipeName[,password=Password]
ssl:proto=Protocol,{certuser=Cert|machuser=Cert},server=Server,port=Socket[,password=Password]
ssl:proto=Protocol,{certuser=Cert|machuser=Cert},clicon=Server,port=Socket[,password=Password]
```

The various parameters in the preceding options have the following possible values:

### *Server*

The network name of the computer on which the debugging server was created. Do not precede this name with backslashes (\).

### *PipeName*

If you use the NPIPE or SPIPE protocol, *PipeName* is the name that was given to the pipe when the server was created.

### *Socket*

If you use the TCP or SSL protocol, *Socket* is the same socket port number that was used when the server was created.

### *COMPort*

If you use the COM protocol, *COMPort* specifies the COM port to use. The "COM" prefix is optional (for example, both "com2" and "2" are correct).

### *BaudRate*

If you use the COM protocol, *BaudRate* should match the baud rate that you chose when the server was created.

### *COMChannel*

If you use the COM protocol, *COMChannel* should match the channel number that you chose when the server was created.

#### *Protocol*

(Windows 2000 and later) If you use the SSL or SPIPE protocol, *Protocol* should match the secure protocol that you used when the server was created.

#### *Cert*

(Windows 2000 and later) If you use the SSL or SPIPE protocol, you should use the identical **certuser=Cert** or **machuser=Cert** parameter that was used when the server was created.

#### **clicon**

Specifies that the debugging server will try to connect to the client through a reverse connection. The client must use **clicon** if and only if the server is using **clicon**. In most cases, the debugging client is started before the debugging server when a reverse connection is used.

#### *Password*

If you used a password when the server was created, you must supply *Password* to create the debugging client. This value must match the original password. Passwords are case-sensitive. If the wrong password is supplied, the error message will specify "Error 0x80004005".

#### **ipversion=6**

(Debugging Tools for Windows 6.6.07 and earlier only) Forces the debugger to use IP version 6 rather than version 4 when you are using TCP to connect to the Internet. In Windows Vista and later versions, the debugger attempts to auto-default to IP version 6, making this option unnecessary.

Instead of manually specifying the remote connection parameters, you can press the **Browse** button in the **Connect to Remote Debugger Session** dialog box and use the **Browse Remote Servers** dialog box.

#### **Browse Remote Servers Dialog Box**

In the **Browse Remote Servers** dialog box, in the **Machine** text box, enter the name of the computer that the debugging server is running on. (The two initial backslashes are optional: "MyBox" and "\\MyBox" are both correct.) Then, press the **Refresh** button.

The **Servers** area lists all of the debugging servers that are running on that computer. Select any of the listed servers and then press ENTER or click **OK**. (You can also double-click one of the listed servers.) The proper connection string for the debugging server that you selected will now appear in the **Connection string** box in the **Connect to Remote Debugger Session** dialog box.

If the server is password-protected, the connection string includes **Password=\***. You must replace the asterisk (\*) with the actual password.

After you specify the server and password, click **OK** to open the connection.

This list of servers in the **Browse Remote Servers** dialog box can also include servers that no longer exist but were shut down improperly. If you connect to one of these nonexistent servers, you will receive an error message.

The list of servers does not include process servers and KD connection servers; you can list those servers only by using the [File | Connect to Remote Stub](#) command or by running **cdb -QR Server** from a Command Prompt window.

#### **Additional Information**

For more information and for other methods of joining a remote debugging session, see [Activating a Debugging Client](#).

[Send comments about this topic to Microsoft](#)

# File | Connect to Remote Stub

5/31/2017 • 3 min to read • [Edit Online](#)

Click **Connect to Remote Stub** on the **File** menu to make WinDbg a smart client and connect to a process server or a KD connection server.

This command is equivalent to using the `-premove` command line option in user mode, or the `-k kdsrv` transport protocol command-line option in kernel mode. You can use this command only when WinDbg is in dormant mode.

You cannot use this command to connect to a debugging server; for that purpose, use [File | Connect to Remote Session](#) instead.

## Connect to Remote Stub Server Dialog Box

When you click **Connect to Remote Stub**, the **Connect to Remote Stub Server** dialog box appears. You can use this dialog box to enter the remote connection parameters or to browse a list of process servers and KD connection servers.

To manually specify the remote connection parameters, enter one of the following strings in the **Connection string** box:

```
npipe:server=Server,pipe=PipeName[,password=Password]
tcp:server=Server,port=Socket[,password=Password][,ipversion=6]
tcp:clicon=Server,port=Socket[,password=Password][,ipversion=6]
com:port=COMPort,baud=BaudRate,channel=COMChannel[,password=Password]
spipe:proto=Protocol,{certuser=Cert|machuser=Cert},server=Server,pipe=PipeName[,password=Password]
ssl:proto=Protocol,{certuser=Cert|machuser=Cert},server=Server,port=Socket[,password=Password]
ssl:proto=Protocol,{certuser=Cert|machuser=Cert},clicon=Server,port=Socket[,password=Password]
```

The various parameters in the preceding options have the following possible values:

### *Server*

The network name of the computer on which the process server or KD connection server was created. Do not precede this name with backslashes (\\\).

### *PipeName*

If you use the NPIPE or SPIPE protocol, *PipeName* is the name that was given to the pipe when the server was created.

### *Socket*

If you use the TCP or SSL protocol, *Socket* is the same socket port number that was used when the server was created.

### *COMPort*

If you use the COM protocol, *COMPort* specifies the COM port to use. The "COM" prefix is optional (for example, both "com2" and "2" are correct).

### *BaudRate*

If you use the COM protocol, *BaudRate* should match the baud rate that you chose when the server was created.

### *COMChannel*

If you use the COM protocol, *COMChannel* should match the channel number that you chose when the server was created.

### *Protocol*

(Windows 2000 and later) If you use the SSL or SPIPE protocol, *Protocol* should match the secure protocol that you used when the server was created.

### *Cert*

(Windows 2000 and later) If you use the SSL or SPIPE protocol, you should use the identical **certuser=Cert** or **machuser=Cert** parameter that was used when the server was created.

### **clicon**

Specifies that the process server or KD connection server will try to connect to the client through a reverse connection. The client must use **clicon** if and only if the server is using **clicon**. In most cases, the smart client is started before the server when a reverse connection is used.

### *Password*

If you used a password when the server was created, you must supply *Password* to create the smart client. This value must match the original password. Passwords are case-sensitive. If the wrong password is supplied, the error message will specify "Error 0x80004005".

### **ipversion=6**

(Debugging Tools for Windows 6.6.07 and earlier only) Forces the debugger to use IP version 6 rather than version 4 when you are using TCP to connect to the Internet. In Windows Vista and later versions, the debugger attempts to auto-default to IP version 6, making this option unnecessary.

Instead of manually specifying the remote connection parameters, you can press the **Browse** button in the **Connect to Remote Stub Server** dialog box and use the **Browse Remote Servers** dialog box.

### **Browse Remote Servers Dialog Box**

In the **Browse Remote Servers** dialog box, in the **Machine** text box, enter the name of the computer that the process server or KD connection server is running on. (The two initial backslashes are optional: "MyBox" and "\\MyBox" are both correct.) Then, press the **Refresh** button.

The **Servers** area lists all of the process servers and KD connection servers that are running on that computer. Select any of the listed servers and then press ENTER or click **OK**. (You can also double-click one of the listed servers.) The proper connection string for the process server that you selected will now appear in the **Connection string** box in the **Connect to Remote Stub Server** dialog box.

If the server is password-protected, the connection string includes **Password=\***. You must replace the asterisk (\*) with the actual password.

After you specify the server and password, click **OK** to open the connection.

The list of servers in the **Browse Remote Servers** dialog box can also include servers that no longer exist but were shut down improperly. If you connect to one of these nonexistent servers, you will receive an error message.

The list of servers does not include debugging servers. To view those servers, use the [File | Connect to Remote Session](#) command.

### **Additional Information**

For more information and for other methods of joining a remote stub session, see [Activating a Smart Client](#) and [Activating a Smart Client \(Kernel Mode\)](#).

[Send comments about this topic to Microsoft](#)

# File | Kernel Debug

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Kernel Debug** on the **File** menu to debug a target computer in kernel mode.

This command is equivalent to pressing CTRL+K. You can use this command only when WinDbg is in dormant mode.

## Dialog Box

When you click **Kernel Debug**, the **Kernel Debugging** dialog box appears with these tabs:

- The **COM** tab indicates that the connection will use a COM port. In the **Baud Rate** box, enter the baud rate. In the **Port** box, enter the name of the COM port. For more information, see [Setting Up a Serial Connection Manually](#).

You can also use the COM tab to connect to virtual machine through a named pipe. In the **Port** box, enter `\VMHost\pipe\PipeName`. `VMHost` specifies the name of the physical computer on which the virtual machine is running. If the virtual machine is running on the same computer as the kernel debugger itself, use a single period (.) for `VMHost`. For more information, see [Setting Up a Connection to a Virtual Machine](#).

- The **1394** tab indicates that the connection will use 1394. In the **Channel** box, enter the 1394 channel number. 1394 debugging is supported only if both the host computer and target computer are running Windows XP or later versions of the Windows operating system. For more information, see [Setting Up a 1394 Connection Manually](#).
- The **USB** tab indicates that the connection will use USB 2.0 or USB 3.0. In the **Target Name** box, enter the target name that you created when you configured the target computer. For more information, see [Setting Up a USB 2.0 Connection Manually](#) and [Setting Up a USB 3.0 Connection Manually](#).
- The **NET** tab indicates that the connection will use Ethernet. In the **Port Number** box, enter the port number that you specified when you configured the target computer. In the **Key** box, enter the key that was generated for you (or that you created) when you configured the target computer. For more information, see [Setting Up a Network Connection Manually](#).
- The **Local** tab indicates that WinDbg will perform local kernel debugging. Local kernel debugging is supported only on Windows XP and later.

For more information and for other methods of beginning a kernel debugging session, see [Live Kernel-Mode Debugging Using WinDbg](#).

[Send comments about this topic to Microsoft](#)

# File | Symbol File Path

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Symbol File Path** on the **File** menu to display, set, or append to the symbol path.

This command is equivalent to pressing CTRL+S.

## Symbol Search Path Dialog Box

When you click **Symbol File Path**, the **Symbol Search Path** dialog box appears. This dialog box displays the current symbol path. If the **Symbol path** box is blank, there is no current symbol path.

You can enter a new path or edit the old path. If you want to search more than one directory, separate the directory names with semicolons.

Click **OK** to save changes, or click **Cancel** to discard changes.

If you select the **Reload** check box, the debugger will reload all loaded symbols and images after you click **OK**. The **Reload** command is equivalent to using the [.reload \(Reload Module\)](#) command.

You can also click **Browse** to open the **Browse For Folder** dialog box.

## Browse For Folder Dialog Box

In the **Browse For Folder** dialog box, you can browse through the folders on your computer or your network. You can also click the **Make New Folder** button to create a new folder. If you right-click a file or folder in this dialog box, a standard Windows shortcut menu appears.

Click **OK** to append the selected folder to the symbol path and return to the **Symbol Search Path** dialog box.

## Additional Information

For more information and for other ways to change the symbol path, see [Symbol Path](#).

[Send comments about this topic to Microsoft](#)

# File | Source File Path

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Source File Path** on the **File** menu to display, set, or append to the source path.

This command is equivalent to pressing CTRL+P.

## Source Search Path Dialog Box

When you click **Source File Path**, the **Source Search Path** dialog box appears. This dialog box displays the current source path. If the **Source path** box is blank, there is no current source path.

You can enter a new path or edit the old path. If you want to search more than one directory, separate the directory names with semicolons.

If you are performing remote debugging, the **Local** check box will be available. Select this box to edit your debugging client's local source path; clear it to edit the debugging server's source path.

Click **OK** to save changes, or click **Cancel** to discard changes.

You can also click **Browse** to open the **Browse For Folder** dialog box.

## Browse For Folder Dialog Box

In the **Browse For Folder** dialog box, you can browse through the folders on your computer or your network. You can also click the **Make New Folder** button to create a new folder. If you right-click a file or folder in this dialog box, a standard Windows shortcut menu appears.

Click **OK** to append the selected folder to the source path and return to the **Source Search Path** dialog box.

## Additional Information

For more information and for other ways to change this path, see [Source Path](#).

[Send comments about this topic to Microsoft](#)

# File | Image File Path

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Image File Path** on the **File** menu to display, set, or append to the executable image path.

This command is equivalent to pressing CTRL+I.

## Executable Image Search Path Dialog Box

When you click **Image File Path**, the **Executable Image Search Path** dialog box appears. This dialog box displays the current executable image path. If the **Image path** box is blank, there is no current executable image path.

You can enter a new path or edit the old path. If you want to search more than one directory, separate the directory names with semicolons.

Click **OK** to save changes, or click **Cancel** to discard changes.

If you select the **Reload** check box, the debugger will reload all loaded image and symbol files after you click **OK**.

This command is equivalent to using the [.reload \(Reload Module\)](#) command.

You can also click **Browse** to open the **Browse For Folder** dialog box.

## Browse For Folder Dialog Box

In the **Browse For Folder** dialog box, you can browse through the folders on your computer or your network. You can also use the **Make New Folder** button to create a new folder. If you right-click a file or folder in this dialog box, a standard Windows shortcut menu appears.

Click **OK** to append the selected folder to the executable image path and return to the **Executable Image Search Path** dialog box.

[Send comments about this topic to Microsoft](#)

# File | Open Workspace

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Open Workspace** on the **File** menu to open a saved workspace.

This command is equivalent to pressing CTRL+W.

## Dialog Box

When you click **Open Workspace**, the **Open Workspace** dialog box appears. This dialog box contains a list of all named workspaces in the **Workspaces** area. Default or implicit workspaces are not listed since opening them directly will cause problems with the implicit ordering. If you want to open an implicit workspace directly, you must save it explicitly. For more information on named and default workspaces, see [Creating and Opening a Workspace](#).

Enter the name of the workspace that you want to open in the **Workspace** box or select the workspace name in the **Workspaces** area. Then, click **OK** to open the selected workspace, or click **Cancel** to return the debugger to its previous state.

## Additional Information

For more information about the different levels of workspaces and how to use them, see [Using Workspaces](#).

[Send comments about this topic to Microsoft](#)

# File | Save Workspace

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Save Workspace** on the **File** menu to save the current workspace under its current workspace name.

## Additional Information

For more information about the different levels of workspaces and how to use them, see [Using Workspaces](#).

[Send comments about this topic to Microsoft](#)

# File | Save Workspace As

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Save Workspace As** on the **File** menu to save the current workspace under a new workspace name.

## Dialog Box

When you click **Save Workspace As**, the **Save Workspace As** dialog box appears. This dialog box contains a list of all existing workspace names in the **Workspaces** area. The name of the current workspace is shown in the **Workspace** box.

Enter the name that you want to use to save the workspace in the **Workspace** box, select the workspace name in the **Workspaces** area, or just leave the current name as it exists.

Click **OK** to save the workspace, or click **Cancel** to not save the workspace.

## Additional Information

For more information about the different levels of workspaces and how to use them, see [Using Workspaces](#).

[Send comments about this topic to Microsoft](#)

# File | Clear Workspace

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Clear Workspace** on the **File** menu to erase items in the current workspace.

## Dialog Box

When you click **Clear Workspace**, the **Clear Workspace** dialog box appears. This dialog box contains a list of all of the items that are contained in the current workspace in the **Items in Workspace** area.

Use the **Clear** and **Clear All** buttons to remove items from the **Items in Workspace** area. If you make an error, use the **Save** and **Save All** buttons to return items to this list.

Click **OK** to make these changes, or click **Cancel** to discard these changes.

## Additional Information

For more information about the different levels of workspaces and how to use them, see [Using Workspaces](#).

[Send comments about this topic to Microsoft](#)

# File | Delete Workspaces

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Delete Workspaces** on the **File** menu to delete one or more existing workspaces.

## Dialog Box

When you click **Delete Workspaces**, the **Delete Workspaces** dialog box appears. In this dialog box, select the workspace that you want to delete and click **Delete**.

Click **Close** to close the dialog box.

## Additional Information

For more information about the different levels of workspaces and how to use them, see [Using Workspaces](#).

[Send comments about this topic to Microsoft](#)

# File | Open Workspace in File

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Open Workspace in File** on the **File** menu to load a workspace that was previously saved to a file.

## Dialog Box

When you click **Open Workspace in File**, the **Open Workspace in File** dialog box appears. In this dialog box, enter the name of the file that you want to load, or use the **Look in** list to navigate to the file and select it. (Workspace files should use the .wew extension.)

Click **OK** to load the workspace, or click **Cancel** to close the dialog box.

## Additional Information

For more information about the different levels of workspaces and how to use them, see [Using Workspaces](#).

[Send comments about this topic to Microsoft](#)

# File | Save Workspace to File

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Save Workspace to File** on the **File** menu to save the current workspace to a file.

## Dialog Box

When you click **Save Workspace to File**, the **Save Workspace to File** dialog box appears. In this dialog box, enter the name of the file that you want to save the workspace as. Then, use the **Save in** list to navigate to the directory where you want to save the file, or select a specific file you want to overwrite. (The default file extension is .wew.)

Click **OK** to save the file, or click **Cancel** to exit.

## Additional Information

For more information about the different levels of workspaces and how to use them, see [Using Workspaces](#).

# File | Map Network Drive

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Map Network Drive** on the **File** menu to add network connections and assign drive letters to these connections.

## Dialog Box

When you click **Map Network Drive**, the **Map Network Drive** dialog box appears. Use the **Drive** and **Folder** menus to choose a server and share and assign a drive letter to it.

This dialog box works exactly like the corresponding feature of Windows Explorer.

The **File | Map Network Drive** command affects only the network connections of the computer on which WinDbg is running. If you are using WinDbg as a client in a remote debugging session and you want to change the network connections of the server, you must use a **.shell net use** command.

## Additional Information

For more information about accessing the command shell, see [Using Shell Commands](#).

[Send comments about this topic to Microsoft](#)

# File | Disconnect Network Drive

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Disconnect Network Drive** on the **File** menu to remove network connections.

## Dialog Box

When you click **Disconnect Network Drive**, the **Disconnect Network Drives** dialog box appears. In the **Network Drives** box, select the connection you want to remove and click **OK**.

This dialog box works exactly like the corresponding feature of Windows Explorer.

The **File | Disconnect Network Drive** command affects only the network connections of the computer on which WinDbg is running. If you are using WinDbg as a client in a remote debugging session and you want to change the network connections of the server, you must use a **.shell net use** command.

## Additional Information

For more information about accessing the command shell, see [Using Shell Commands](#).

[Send comments about this topic to Microsoft](#)

# File | Recent Files

5/26/2017 • 1 min to read • [Edit Online](#)

Point to **Recent Files** on the **File** menu to display a list of the four source files that you most recently opened in WinDbg.

To open one of these files, click its name from the menu.

## Additional Information

For more information about source files and source paths, and for other ways to load source files, see [Source Path](#).

[Send comments about this topic to Microsoft](#)

# File | Exit

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Exit** on the **File** menu to end the debugging session and exit WinDbg.

This command is equivalent to pressing ALT+F4.

## Additional Information

For more information about exiting WinDbg or ending the debugging session, see [Ending a Debugging Session in WinDbg](#).

[Send comments about this topic to Microsoft](#)

# Edit Menu

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the following commands on the **Edit** menu of WinDbg:

[Edit | Cut](#)

[Edit | Copy](#)

## **Edit | Copy Formatted**

[Edit | Paste](#)

[Edit | Select All](#)

[Edit | Write Window Text to File](#)

## **Edit | Copy Window Text to Clipboard**

[Edit | Add to Command Output](#)

[Edit | Clear Command Output](#)

[Edit | Evaluate Selection](#)

[Edit | Display Selected Type](#)

[Edit | Find](#)

[Edit | Find Next](#)

[Edit | Go to Address](#)

[Edit | Go to Line](#)

[Edit | Go to Current Instruction](#)

[Edit | Set Current Instruction](#)

[Edit | Breakpoints](#)

[Edit | Open/Close Log File](#)

[Send comments about this topic to Microsoft](#)

# Edit | Cut

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Cut** on the **Edit** menu to delete any text that you have selected and to move it to the clipboard.

This command is equivalent to pressing CTRL+X or SHIFT+DELETE or clicking the **Cut (Ctrl+X)** button (  ) on the toolbar.

You can use the **Cut** command on the **Edit** menu only with docked or tabbed windows, but you can use the shortcut keys and the toolbar button with any window that supports this feature.

## Additional Information

For more information about how to select, copy, cut, and paste text and about how these operations vary from window to window, see [Cutting and Pasting Text](#).

[Send comments about this topic to Microsoft](#)

# Edit | Copy

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Copy** on the **Edit** menu to copy to the clipboard any text that you have selected.

This command is equivalent to pressing CTRL+C or CTRL+INSERT or clicking the **Copy (Ctrl+C)** button (

You can use the **Copy** command only with docked or tabbed windows. You can use the shortcut keys and the toolbar button with any window that supports this feature.

## Additional Information

For more information about how to select, copy, cut, and paste text and about how these operations vary from window to window, see [Cutting and Pasting Text](#).

[Send comments about this topic to Microsoft](#)

# Edit | Paste

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Paste** on the **Edit** menu to paste text from the clipboard to the current cursor location.

This command is equivalent to pressing CTRL+V or SHIFT+INSERT or clicking the **Paste (Ctrl+V)** button (

You can use the **Paste** command only with docked or tabbed windows. But you can use the shortcut keys and the toolbar button with any window that supports this feature.

## Additional Information

For more information about how to select, copy, cut, and paste text and about how these operations vary from window to window, see [Cutting and Pasting Text](#).

[Send comments about this topic to Microsoft](#)

# Edit | Select All

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Select All** on the **Edit** menu to select all of the text in the active [Debugger Command window](#), [Disassembly window](#), [Source window](#), or dialog box.

This command is equivalent to pressing CTRL+A.

## Additional Information

For more information about how to select, copy, cut, and paste text and about how these operations vary from window to window, see [Cutting and Pasting Text](#).

[Send comments about this topic to Microsoft](#)

# Edit | Write Window Text to File

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Write Window Text to File** on the **Edit** menu to save all of the text in the active debugging information window to a file.

This command is available only if the active window is the [Debugger Command window](#), [Calls window](#), or [Scratch Pad](#).

## Dialog Box

When you click **Write Windows Text to File**, the **Write Window Text to File** dialog box appears. In this dialog box, enter the name of the file where you want to save the window text. You can browse in the **Save in** list to the directory that you want or select a specific file that you want to overwrite. The default file name extension is .txt.

Click **Save** to save the file or click **Cancel** to exit.

## Additional Information

For more information about how to select, copy, cut, and paste text and about how these operations vary from window to window, see [Cutting and Pasting Text](#).

[Send comments about this topic to Microsoft](#)

# Edit | Add to Command Output

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Add to Command Output** on the **Edit** menu to insert a comment into the [Debugger Command window](#).

Type a comment into the **Text** box and then click **OK**.

Your comment appears in the Debugger Command window and in any open log file. However, the comment does not appear in any Windows debuggers that are remotely connected to your session.

## Additional Information

For more information about other features of the Debugger Command window, see [Using Debugger Commands](#).

[Send comments about this topic to Microsoft](#)

# Edit | Clear Command Output

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Clear Command Output** on the **Edit** menu to clear all of the text from the [Debugger Command window](#) and clear the command history.

## Additional Information

For more information about other features of the Debugger Command window, see [Using Debugger Commands](#).

[Send comments about this topic to Microsoft](#)

# Edit | Evaluate Selection

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Evaluate Selection** on the **Edit** menu to evaluate the current selection in the [Source window](#) and display the result in the [Debugger Command window](#).

This command is equivalent to pressing CTRL+SHIFT+V, clicking **Evaluate selection** on the Source window's shortcut menu, or using the [?? \(Evaluate C++ Expression\)](#) command together with the selected text as its argument.

If the selected text includes more than one line, a syntax error results. If no text is selected in a Source window, you cannot use this command.

## Additional Information

For more information about other features of Source windows, see [Source Window](#).

[Send comments about this topic to Microsoft](#)

# Edit | Display Selected Type

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Display Selected Type** on the **Edit** menu to determine the data type of the current selection in the [Source window](#) and to display the type in the [Debugger Command window](#).

This command is equivalent to pressing CTRL+SHIFT+Y or clicking **Display selected type** on the Source window's shortcut menu.

If the selected text includes more than a single object, a syntax error or other irregular results might be displayed. If no text is selected in a Source window, you cannot use this command.

## Additional Information

For more information about other features of Source windows, see [Source Window](#).

[Send comments about this topic to Microsoft](#)

# Edit | Find

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Find** on the **Edit** menu to find text in the active debugging information window.

**Note** The active window must be the [Debugger Command window](#) or a [Source window](#).

This command is equivalent to pressing CTRL+F.

## Dialog Box

When you click **Find**, the **Find** dialog box appears. In this dialog box, in the **Find what** box, enter the text that you want to find. If there is already text selected, this text automatically appears in the **Find what** box.

In the **Direction** area, click **Up** or **Down** to specify the direction of your search. The search begins wherever the cursor is in the window. You can put the cursor at any location by using the mouse pointer.

Select **Match whole word only** if you want to search for a single whole word. (If you select this option when you search for multiple words, you always receive a failed search.)

Select **Match case** to perform a case-sensitive search.

The **Find** command only changes the WinDbg display. This command does not affect the execution of the target or any other debugger operations.

After you close the **Find** dialog box, you can repeat the search in a forward direction by using the [Edit | Find Next](#) command or pressing F3. You can repeat the search in a backward direction by pressing SHIFT+F3.

## Additional Information

For more information about other ways to find text in debugging information windows, see [Moving Through a Window](#).

[Send comments about this topic to Microsoft](#)

# Edit | Find Next

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Find Next** on the **Edit** menu to repeat the previous search and find the next match.

This command is equivalent to pressing F3.

To repeat the search in a backward direction, press SHIFT+F3.

If you have not previously performed any searches, use the **Edit | Find Next** command, press F3, or press SHIFT+F3 to open the **Find** dialog box (similar to the **Edit | Find** command).

## Additional Information

For more information about other ways of finding text in debugging information windows, see [Moving Through a Window](#).

[Send comments about this topic to Microsoft](#)

# Edit | Go to Address

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Go to Address** on the **Edit** menu to go to an address in the target's virtual address space.

This command is equivalent to pressing CTRL+G.

## Dialog Box

When you click **Go to Address**, the **View Code Offset** dialog box appears. In this dialog box, enter the address that you want to move to. This address can be an expression (such as a function, symbol, or integer memory address) or any valid address expression. If the address is ambiguous, the dialog box displays a list that contains all of the ambiguous items.

**Note** If you put the cursor on a line within the [Disassembly window](#) or a [Source window](#) and then use the **Go to Address** command, the address of the line that you have selected will appear in the **View Code Offset** dialog box. You can use this address or replace it with any address of your choice.

After you click **OK**, the debugger moves the caret (^) to the beginning of the function or address in the Disassembly window or a Source window.

You can use the **Go to Address** command in any window that is currently active. If the debugger is in disassembly mode, WinDbg finds the address in the Disassembly window. If the debugger is in source mode, WinDbg finds the address in a Source window. If the address cannot be found in a Source window, WinDbg finds it in the Disassembly window. If the appropriate window is not open, WinDbg opens it.

The **Go to Address** command only changes the WinDbg display. This command does not affect the execution of the target or any other debugger operations.

## Additional Information

For more information about other ways of finding text in debugging information windows, see [Moving Through a Window](#).

[Send comments about this topic to Microsoft](#)

# Edit | Go to Line

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Go to Line** on the **Edit** menu to search for a specific line in the currently-active [Source window](#). If the active window is not a Source window, this command has no effect.

This command is equivalent to pressing CTRL+L.

## Dialog Box

When you click **Go to Line**, the **Go to Line** dialog box appears. In this dialog box, enter the line number that you want to find and then click **OK**. The debugger will move the caret (^) to that line. If the line number is bigger than the last line in the file, the cursor will move to the end of the file.

The **Go to Line** command only changes the WinDbg display. This command does not affect the execution of the target or any other debugger operations.

## Additional Information

For more information about other ways of finding text in debugging information windows, see [Moving Through a Window](#).

[Send comments about this topic to Microsoft](#)

# Edit | Go to Current Instruction

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Go to Current Instruction** on the **Edit** menu to open the debugging information window that contains the current instruction and to highlight this instruction.

This command is equivalent to pressing ALT+ASTERISK (using the ASTERISK key on the numeric keypad).

If the current instruction corresponds to a known source file, WinDbg opens the [Source window](#) that contains this source file. If no such window exists, WinDbg opens one. The current line is highlighted.

If the current instruction is not in a known source file and the [Disassembly window](#) is open, WinDbg opens the Disassembly window and the current line is highlighted. However, if the Disassembly window is closed, the **Go to Current Instruction** command does not open it.

This command only changes the WinDbg display. This command does not affect the execution of the target or any other debugger operations.

[Send comments about this topic to Microsoft](#)

# Edit | Set Current Instruction

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Set Current Instruction** on the **Edit** menu to change the value of the instruction pointer to the instruction that corresponds to the current line in the active [Source window](#).

This command is equivalent to pressing CTRL+SHIFT+I or clicking **Set instruction pointer to current line** on the Source window's shortcut menu.

[Send comments about this topic to Microsoft](#)

# Edit | Breakpoints

5/26/2017 • 4 min to read • [Edit Online](#)

Click **Breakpoints** on the **Edit** menu to display or control breakpoints.

This command is equivalent to pressing ALT+F9. If a [source window](#) or the [disassembly window](#) is not active, you can also press f9 or click the **insert or remove breakpoint (f9)** button (

However, if a Source window or the Disassembly window is open, the **Insert or remove breakpoint (F9)** button and the F9 key set a breakpoint on the current line. (If there is already a breakpoint set at the current line, this button or key will remove the breakpoint.)

If a statement or call spans multiple lines, WinDbg sets the breakpoint on the last line of the statement or call. You should insert the caret (^) on or before the statement to set a breakpoint for the whole statement. If the debugger cannot set a breakpoint at the current caret position, it will search in a downward direction for the next allowed position and insert the breakpoint there.

## Dialog Box

When you click **Breakpoints**, the **Breakpoints** dialog box appears. This dialog box displays all current breakpoint information and is presented in the following columns:

- The breakpoint number. This number is a decimal number that you can use to refer to the breakpoint in future commands.
- The breakpoint status. This status can be **e** (enabled) or **d** (disabled).
- (Unresolved breakpoints only) The letter **u**. This letter appears if the breakpoint is unresolved (that is, it does not match any currently-loaded module address). For details, see [Unresolved Breakpoints \(bu Breakpoints\)](#).
- The virtual address of the breakpoint. If you have enabled the loading of source line numbers, the display includes file and line number information instead of address offsets. If the breakpoint is unresolved, the address appears at the end of the listing instead of here.
- (Processor breakpoints only) Type and size information. This information can be **e** (execute), **r** (read/write), **w** (write), or **i** (input/output). These types are followed with the size of the block, in bytes. For details, see [Processor Breakpoints \(ba Breakpoints\)](#).
- The number of passes that are remaining until the breakpoint becomes active, followed by the initial number of passes in parentheses. The number of times that the program counter passes through the breakpoint without breaking is one less than the value of this number. Therefore, this number is never lower than 1. Note also that this number counts only the times the application executes through this point. In other words, stepping over this point does not count. After the full count has been reached, you can reset the count only by clearing and resetting the breakpoint.
- The associated process and thread. If thread is given with three asterisks (\*\*\*) this breakpoint is not a thread-specific breakpoint.
- The module and function, with offset, that correspond to the breakpoint address. If the breakpoint is unresolved, the breakpoint address appears here, in parentheses. If the breakpoint is set on a valid address but symbol information is missing, this column will be blank.
- The command string that is automatically executed when this breakpoint is hit. This command string is displayed in quotation marks. If the breakpoint is hit, the commands in this command string are executed

until application execution resumes. Any command that resumes program execution (such as **g** or **t**) will stop the execution of the command list.

If you select any breakpoint, you can then click the **Remove**, **Disable**, or **Enable** button. The **Remove** button permanently removes the breakpoint. The **Disable** button temporarily deactivates the breakpoint. The **Enable** button re-enables a disabled breakpoint.

The **Remove All** button permanently removes all breakpoints.

You can also enter commands in the **Command** box in the following ways:

- If you enter a **bp (Set Breakpoint)**, **bu (Set Unresolved Breakpoint)**, **bm (Set Symbol Breakpoint)**, **ba (Break on Access)**, **bc (Breakpoint Clear)**, **bd (Breakpoint Disable)**, or **be (Breakpoint Enable)** command, the **Command** box works as if you were entering the command in the [Debugger Command window](#). However, the command itself must be in lowercase letters. The command cannot begin with a thread specifier. If you want to use a thread specifier, enter it in the **Thread** box without the initial tilde (~).
- If you enter any other text, the text will be treated as the argument string for a **bu (Set Unresolved Breakpoint)** command. That is, the debugger prefixes your entry with **bu** and a space and then executes it as a command.

When you are entering a new breakpoint, you can also do the following:

- Create a thread-specific breakpoint by entering a thread specifier in the **Thread** box. Do not include the tilde (~) character that is typically prefixed to a thread specifier.
- Create a conditional breakpoint by entering a condition in the **Condition** box. The condition can be any evaluable expression, and it will be evaluated according to the current expression syntax (see [Evaluating Expressions](#)). For more information about these types of breakpoints, see [Setting a Conditional Breakpoint](#).

## Additional Information

For more information about how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and setting breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

[Send comments about this topic to Microsoft](#)

# Edit | Open/Close Log File

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Open/Close Log File** on the **Edit** menu to write to a new log file, append to an existing log file, or close an open log file.

## Dialog Box

When you click **Open/Close Log File**, the **Open/Close Log File** dialog box appears. This dialog box displays the current log file, if one is already open.

If the **Log file name** box is blank, you can enter a log file name. If this file already exists, WinDbg overwrites the existing file, unless you select the **Append** check box. If you specify a file name but no path, WinDbg puts the file in the default directory that you started WinDbg from.

If the **Log file name** box already displays a file name, you can click **Close Open Log File** to close the file. If you clear the **Log file name** box and enter a new log file name, the previous log file will be closed.

Click **OK** to save changes, or click **Cancel** to discard changes.

If you click **OK** when no log file name appears in the **Log file name** box, it has no effect. That is, WinDbg does not close a log file or open a log file.

However, if a log file is already active and you click **OK** without clearing its name or selecting **Append**, WinDbg deletes the log file and uses a new file that has the same name.

[Send comments about this topic to Microsoft](#)

# View Menu

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the following commands on the **View** menu of WinDbg:

[View | Command](#)

[View | Watch](#)

[View | Locals](#)

[View | Registers](#)

[View | Memory](#)

[View | Call Stack](#)

[View | Disassembly](#)

[View | Scratch Pad](#)

[View | Processes and Threads](#)

[View | Command Browser](#)

**View | Recent Commands**

**[View | Set Browser Start Command](#)**

[View | Verbose Output](#)

**View | Event Timestamps**

[View | Show Version](#)

[View | Toolbar](#)

[View | Status Bar](#)

[View | Font](#)

[View | Options](#)

[View | Source language file extensions](#)

[View | WinDbg Command Line](#)

[Send comments about this topic to Microsoft](#)

# View | Command

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Command** on the **View** menu to open the [Debugger Command window](#). If this window is already open, it becomes active.

This command is equivalent to pressing ALT+1 or clicking the **Command (Alt+1)** button (  ) on the toolbar.

For more information about this window and its uses, see [Debugger Command Window](#).

[Send comments about this topic to Microsoft](#)

# View | Watch

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Watch** on the **View** menu to open the Watch window. If this window is already open, it becomes active.

This command is equivalent to pressing ALT+2 or clicking the **Watch (Alt+2)** button () on the toolbar.

[Send comments about this topic to Microsoft](#)

# View | Locals

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Locals** on the **View** menu to open the Locals window. If this window is already open, it becomes active.

This command is equivalent to pressing ALT+3 or clicking the **Locals (Alt+3)** button (  ) on the toolbar.

For more information about this window and its uses, see [Locals Window](#).

[Send comments about this topic to Microsoft](#)

# View | Registers

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Registers** on the **View** menu to open the [Registers window](#). If this window is already open, it becomes active.

This command is equivalent to pressing ALT+4 or clicking the **Registers (Alt+4)** button (  ) on the toolbar.

For more information about this window and its uses, see [Registers Window](#).

[Send comments about this topic to Microsoft](#)

# View | Memory

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Memory** on the **View** menu to open a new [Memory window](#).

**Note** You can have multiple Memory windows open at the same time. Each window can display a different region of memory. Only the Memory window and the [Source window](#) have this ability. All other debugging information windows are limited to a single instance.

The **View** command is equivalent to pressing ALT+5 or clicking the **Memory window (Alt+5)** button (  ) on the toolbar.

For more information about this window and its uses, see [Memory Window](#).

[Send comments about this topic to Microsoft](#)

# View | Call Stack

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Call Stack** on the **View** menu to open the [Calls window](#). If this window is already open, it becomes active.

This command is equivalent to pressing ALT+6 or clicking the **Call stack (Alt+6)** button () on the toolbar.

For more information about this window and its uses, see [Calls Window](#).

[Send comments about this topic to Microsoft](#)

# View | Disassembly

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Disassembly** on the **View** menu to open the [Disassembly window](#). If this window is already open, it becomes active.

This command is equivalent to pressing ALT+7 or clicking the **Disassembly (Alt+7)** button (  ) on the toolbar.

For more information about this window and its uses, see [Disassembly Window](#).

[Send comments about this topic to Microsoft](#)

# View | Scratch Pad

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Scratch Pad** on the **View** menu to open the Scratch Pad. If this window is already open, it becomes active.

This command is equivalent to pressing ALT+8 or clicking the **Scratch Pad (Alt+8)** button (□) on the toolbar.

[Send comments about this topic to Microsoft](#)

# View | Processes and Threads

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Processes and Threads** on the **View** menu to open the [Processes and Threads window](#). If this window is already open, it becomes active.

This command is equivalent to pressing ALT+9 or clicking the **Processes and Threads (Alt+9)** button (  ) on the toolbar.

For more information about this window and its uses, see [Processes and Threads Window](#).

[Send comments about this topic to Microsoft](#)

# View | Command Browser

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Command Browser** on the **View** menu to open the **Command Browser window**. If this window is already open, it becomes active.

This command is equivalent to pressing CTRL+N or clicking the **Command Browser (Ctrl+N)** button (✉) on the toolbar.

For more information about this window and its uses, see [Command Browser Window](#).

[Send comments about this topic to Microsoft](#)

# View | Verbose Output

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Verbose Output** on the **View** menu to turn verbose mode on and off.

This command is equivalent to pressing CTRL+ALT+V. (and to pressing CTRL+V in KD).

When verbose mode is turned on, some display commands (such as register dumping) produce more detailed output. Every MODULE LOAD operation that is sent to the debugger is displayed. And every time that a driver or DLL is loaded by the operating system, the debugger is notified.

[Send comments about this topic to Microsoft](#)

# View | Show Version

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Show Version** on the **View** menu to display version information about the debugger and all loaded extension DLLs. This information is displayed in the [Debugger Command window](#).

This command is equivalent to pressing CTRL+ALT+W (and pressing CTRL+W in KD).

This command has the same effect as the [version \(Show Debugger Version\)](#) command, except that the latter command also displays the version of the Microsoft Windows operating system.

[Send comments about this topic to Microsoft](#)

# View | Toolbar

5/26/2017 • 1 min to read • [Edit Online](#)

Select or clear **Toolbar** on the **View** menu to cause the toolbar to appear or disappear.

For more information about how to use the toolbar, see [Using the Toolbar and Status Bar](#). For more information about each toolbar button, see [Toolbar Buttons](#).

[Send comments about this topic to Microsoft](#)

# View | Status Bar

5/26/2017 • 1 min to read • [Edit Online](#)

Select or clear **Status Bar** on the **View** menu to cause the status bar to become visible or invisible.

For more information about how to use the status bar, see [Using the Toolbar and Status Bar](#).

[Send comments about this topic to Microsoft](#)

# View | Font

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Font** on the **View** menu to change the font that appears in the debugging information windows.

This command is equivalent to clicking the **Font** button () on the toolbar.

## Dialog Box

When you click **Font**, the **Font** dialog box appears. In this dialog box, you can select the font, style, and size from the appropriate lists. You can also select the script from a drop-down menu to get the appropriate alphabet. To accept your changes, click **OK**.

Click **Cancel** to cancel changes to the font.

## Additional Information

For more information about how to change the character display of the debugging information windows, see [Changing Text Properties](#).

[Send comments about this topic to Microsoft](#)

# View | Options

5/26/2017 • 3 min to read • [Edit Online](#)

Click **Options** on the **View** menu to open the **Options** dialog box. This command is equivalent to clicking the  button on the toolbar.

## Dialog Box

In the **Options** dialog box, you can select or deselect the following options:

### Tab width

The **Tab width** box controls how tab characters are displayed in any Source window. In the **Tab width** box, enter the number of spaces that you want to have between each tab setting. (The default setting is 8. For more information about text properties, see [Changing Text Properties](#).)

### Reuse after opening this many

The **Reuse after opening this many** box controls the number of document, or source, windows that can be open at the same time. If the specified number of source windows has been reached, opening a new window causes an existing window to close. Windows that are marked as tab-dock targets do not close. The last windows to close are the ones you used most recently.

### Parse source languages

If the **Parse source languages** check box is selected, the text of source code in all Source windows is colored according to a simple parse of the source syntax. To change the colors, in the **Colors** area of the dialog box, select a syntax element and then click **Change**. (To turn the syntax colors off in a single Source window, open that window's shortcut menu, click **Select source language**, and then click **<None>**.)

### Evaluate on hover

If the **Evaluate on hover** check box is selected (and the **Parse source languages** check box is selected as well), symbols in a Source window will be evaluated when you select that window and then hover over a symbol with the mouse. The evaluation is the same as that produced by the **dt (Display Type)** command.

### Enter repeats last command

If the **Enter repeats last command** check box is selected, you can press the ENTER key at an empty prompt in the [Debugger Command window](#) to repeat the previous command. If you clear this check box, the ENTER key generates a new prompt.

### Automatically scroll

The **Automatically scroll** check box controls the automatic scrolling that occurs when new text is sent to the Debugger Command window. If you want to turn off this feature, clear the **Automatically scroll** check box. For more information about this scrolling, see [Using Debugger Commands](#).

### Workspace Prompts

In the **Workspace Prompts** area, you can click one of three options to determine when and how frequently the workspace is saved in WinDbg.

- If you click **Always ask**, when a workspace changes (such as when a debugging session ends), the debugger displays the **Workspace save** dialog box where you can save the workspace.

In the **Workspace save** dialog box, if you click **Don't ask again**, WinDbg resets the **Workspace Prompts** option to **Never save** or **Always save**.

- If you click **Always save**, the workspace is saved automatically whenever it changes.

- If you click **Never save**, the workspace is not saved when it changes, and you are not prompted to save it.

### QuickEdit Mode

If the **QuickEdit Mode** check box is selected, you can right-click an item to copy or paste, depending on the window selection state. When you clear this check, QuickEdit is disabled and you can right-click an item to open a shortcut menu for the window. You cannot give individual windows different settings; the QuickEdit setting applies globally to all windows. By default, this box is selected. The QuickEdit setting is saved in the current workspace.

### Colors

To change the color of the source text that is displayed, select an item from the **Colors** area and then click **Change**. Select a color, or select a custom color, and then click **OK**.

In the **Colors** menu, you can change the colors of the following items:

- The first ten items represent text in the [Disassembly window](#) and the [Source window](#).
- The **Changed data text** item represents data entries that have been changed (for example, in the [Registers window](#)).
- The ten **Source Xxx** items control the colors that are used for syntax elements in the Source window.
- The remaining items refer to different kinds of text in the Debugger Command window.

These color changes take effect when you click **OK**. To discard these changes, click **Cancel**.

[Send comments about this topic to Microsoft](#)

# View | Source language file extensions

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Source language file extensions** on the **View** menu to control the file name extensions that WinDbg recognizes as source file name extensions. You can also specify which programming languages are associated with which file name extensions.

## Dialog Box

When you click **Source language file extensions**, the **File Extensions for Source Languages** dialog box appears. In this dialog box, you can add or delete file name extensions by inserting the cursor in the **Extensions and languages** box and typing the appropriate information. Make sure that you specify the appropriate programming language for each file name extension. For example, **cxx=C++** indicates that a .cxx file name extension is a source file and that the corresponding programming language of any file that has that extension is C++. Click **OK** to implement your changes, or click **Cancel** to discard any changes.

[Send comments about this topic to Microsoft](#)

# View | WinDbg Command Line

5/26/2017 • 1 min to read • [Edit Online](#)

Click **WinDbg Command Line** on the **View** menu to display the command that was used to open the current WinDbg session.

The command appears in a small message window. Click **OK** to close this window.

[Send comments about this topic to Microsoft](#)

# Debug Menu

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the following commands on the **Debug** menu of WinDbg:

[Debug | Go](#)

[Debug | Go Unhandled Exception](#)

[Debug | Go Handled Exception](#)

[Debug | Restart](#)

[Debug | Stop Debugging](#)

[Debug | Detach Debuggee](#)

[Debug | Break](#)

[Debug | Step Into](#)

[Debug | Step Over](#)

[Debug | Step Out](#)

[Debug | Run to Cursor](#)

[Debug | Source Mode](#)

[Debug | Resolve Unqualified Symbols](#)

[Debug | Event Filters](#)

[Debug | Modules](#)

[Debug | Kernel Connection | Cycle Baud Rate](#)

[Debug | Kernel Connection | Cycle Initial Break](#)

[Debug | Kernel Connection | Resynchronize](#)

[Send comments about this topic to Microsoft](#)

# Debug | Go

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Go** on the **Debug** menu to resume (or begin) execution on the target. This execution will continue until a breakpoint is reached, an exception or event occurs, the process ends, or the debugger breaks into the target.

This command is equivalent to pressing F5 or clicking the **Go (F5)** button (  ) on the toolbar.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#).

[Send comments about this topic to Microsoft](#)

# Debug | Go Unhandled Exception

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Go Unhandled Exception** on the **Debug** menu to resume execution on the target and to treat the current exception as unhandled.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#). For more information about exceptions and other events, see [Controlling Exceptions and Events](#).

[Send comments about this topic to Microsoft](#)

# Debug | Go Handled Exception

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Go Handled Exception** on the **Debug** menu to resume execution on the target and to treat the current exception as handled.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#). For more information about exceptions and other events, see [Controlling Exceptions and Events](#).

[Send comments about this topic to Microsoft](#)

# Debug | Restart

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Restart** on the **Debug** menu to stop the target's execution and end the target process and all its threads. This command then restarts the target execution at the beginning of the process.

This command is equivalent to pressing CTRL+SHIFT+F5 or clicking the **Restart (Ctrl+Shift+F5)** button (↻) on the toolbar.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#). For more information about how to exit WinDbg or end the debugging session, see [Ending a Debugging Session in WinDbg](#).

[Send comments about this topic to Microsoft](#)

# Debug | Stop Debugging

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Stop Debugging** on the **Debug** menu to stop the target's execution and end the target process and all its threads. This action enables you to start to debug a different target application.

This command is equivalent to pressing SHIFT+F5 or clicking the **Stop debugging (Shift+F5)** button (  ) on the toolbar.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#).

[Send comments about this topic to Microsoft](#)

# Debug | Detach Debuggee

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Detach Debuggee** on the **Debug** menu to detach from the target application and leave it running.

Detaching from the target is supported under one of the following conditions:

- (Microsoft Windows XP and later versions of Windows) You are debugging a running user-mode target.
- You are noninvasively debugging a user-mode target.

If you are debugging a live target on Windows 2000, the **Detach Debuggee** command is not available, because this version of Windows does not support detaching from a target process.

For more information about how to exit the debugger or detach from the target, see [Ending a Debugging Session in WinDbg](#).

[Send comments about this topic to Microsoft](#)

# Debug | Break

5/26/2017 • 2 min to read • [Edit Online](#)

Click **Break** on the **Debug** menu to stop the target's execution and return control to the debugger.

In user mode, this command stops the process and its threads, enabling you to regain control of the debugger. In kernel mode, this command breaks into the target computer.

You can also use this command while the debugger is active. In this situation, the command will truncate long [Debugger Command window](#) displays.

The **Break** command is equivalent to pressing CTRL+BREAK or clicking the **Break (Ctrl+Break)** button (  ) on the toolbar.

## ALT+DEL

You can use **ALT+DEL** to send a **Break**. **ALT+DEL** works the same as **Break (Ctrl+Break)**.

## User-Mode Effects

In user mode, the **Break** command causes the target application to break into the debugger. The target application stops, the debugger becomes active, and you can enter debugger commands.

If the debugger is already active, **Break** does not affect the target application. However, you can use this command to terminate a debugger command. For example, if you have requested a long display and do not want to see any more of it, **Break** will end the display and return you to the debugger command prompt.

When you are performing remote debugging with WinDbg, you can press the Break key on the host computer's keyboard. If you want to issue a break from the target computer's keyboard, use CTRL+C on an x86-based computer.

You can press the F12 key to open a command prompt when the application that is being debugged is busy. Click one of the target application's windows and press F12 on the target computer.

## Kernel-Mode Effects

In kernel mode, the **Break** command causes the target computer to break into the debugger. This command locks the target computer and wakes up the debugger.

When you are debugging a system that is still running, you must press the Break key on the host keyboard to open an initial command prompt.

If the debugger is already active, **Break** does not affect the target computer. However, you can use this command to terminate a debugger command. For example, if you have requested a long display and do not want to see any more of it, **Break** will end the display and return you to the debugger command prompt.

You can also use **Break** to open a command prompt when a debugger command is generating a long display or when the target computer is busy. When you are debugging an x86-based computer, you can also press CTRL+C on the target keyboard to have the same effect.

The SYSRQ key (or pressing ALT+SYSRQ on an enhanced keyboard) is similar. This key works from the host or target keyboard on any processor. However, this key works only if you have opened the prompt by pressing CTRL+C at least one time before.

You can disable the SYSRQ key by editing the registry. In the `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\i8042prt\Parameters` registry key, create a value named **BreakOnSysRq** and set it equal to DWORD 0x0. Then, restart the computer. After you have restarted the

computer, you can press the SYSRQ key on the target computer's keyboard and it will not break into the kernel debugger.

#### **Additional Information**

The corresponding key in KD and CDB is **CTRL+C**. For more information about other ways to control program execution, see [Controlling the Target](#).

[Send comments about this topic to Microsoft](#)

# Debug | Step Into

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Step Into** on the **Debug** menu to execute a single instruction on the target. If the instruction is a function call, the debugger steps into the function.

This command is equivalent to pressing F11 or F8 or clicking the **Step into (F11 or F8)** button (

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#).

[Send comments about this topic to Microsoft](#)

# Debug | Step Over

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Step Over** on the **Debug** menu to execute a single instruction on the target. If the instruction is a function call, the whole function is executed.

This command is equivalent to pressing F10 or clicking the **Step over (F10)** button (F10) on the toolbar.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#).

[Send comments about this topic to Microsoft](#)

# Debug | Step Out

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Step Out** on the **Debug** menu to resume running on the target. This command executes the rest of the current function and breaks when the function return is completed.

This command is equivalent to pressing SHIFT+F11 or clicking the **Step out (Shift+F11)** button  on the toolbar.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#).

[Send comments about this topic to Microsoft](#)

# Debug | Run to Cursor

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Run to Cursor** on the **Debug** menu to resume running on the target. If you insert the cursor on an instruction in the [Disassembly window](#) or a [Source window](#) and then execute this action, WinDbg executes all instructions from the current instruction up to the instruction you have selected.

This command is equivalent to pressing F7 or CTRL+F10 or clicking the **Run to cursor (Ctrl+F10 or F7)** button (  ) on the toolbar.

## Additional Information

For more information about the effects of this action, other methods of issuing this command, and other ways to control program execution, see [Controlling the Target](#).

[Send comments about this topic to Microsoft](#)

# Debug | Source Mode

5/26/2017 • 1 min to read • [Edit Online](#)

Select **Source Mode** on the **Debug** menu to switch the debugger to source mode. Clear **Source Mode** to switch the debugger to assembly mode.

You can click the **Source mode on** button (shown on the left in the following figure) to change the debugger to source mode or click the **Source mode off** button (shown on the right in the following figure) to change the debugger to assembly mode.

When source mode is active, ASM is unavailable on the status bar. When assembly mode is active, ASM is displayed on the status bar.

## Additional Information

For more information about source-mode debugging, see [Debugging in Source Mode](#). For more information about assembly-mode debugging, see [Debugging in Assembly Mode](#).

[Send comments about this topic to Microsoft](#)

# Debug | Resolve Unqualified Symbols

5/26/2017 • 1 min to read • [Edit Online](#)

Select **Resolve Unqualified Symbols** on the **Debug** menu to resolve symbols that have no module prefix.

If you clear **Resolve Unqualified Symbols**, the debugger cannot resolve symbols that have no module prefix. If you do not select **Resolve Unqualified Symbols** and a variable that has no prefix is not already loaded, the debugger does not load any additional symbols to resolve it. You can still use unqualified symbols when this option is clear, but only if they have been previously loaded.

Although we always recommend that you use module qualifiers, you can clear the **Resolve Unqualified Symbols** option to avoid loading symbols that resolve incorrect or misspelled symbols when module qualifiers are not used.

## Additional Information

For more information about symbols, loading symbols, and verifying symbols, see [Symbols](#).

[Send comments about this topic to Microsoft](#)

# Debug | Event Filters

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Event Filters** on the **Debug** menu to open the **Event Filters** dialog box. In this dialog box, you can configure the break status and handling status of exceptions and events.

## Dialog Box

The **Event Filters** dialog box lists all events that the debugger recognizes. You may add numbered exceptions to the list that will then be displayed.

To change the break status for an event, select the event and then click one of the **Execution** option buttons (**Enabled**, **Disabled**, **Output**, or **Ignore**).

To change the handling status for an event, select the event and then click one of the **Continue** option buttons (**Handled** or **Not Handled**).

To add a new numbered exception, click **Add**. When the **Exception Filter** dialog box appears, enter the exception code, click the appropriate button for the break status and handling status, and then click **OK**.

To remove a numbered exception, select the exception and then click **Remove**. You cannot remove the standard events.

When you set the status for the **Load module** or **Unload module** events, you can limit this status to a specific module. Click **Argument**, enter the name of the module or the base address of the module in the **Filter Argument** dialog box, and then click **OK**. You can use **wildcards** when you specify the base address. If you do not specify a module, the break occurs when any module is loaded or unloaded.

When you set the status for the **Debuggee output** event, you can limit this status to a specific output pattern. Click **Argument**, enter the output pattern in the **Filter Argument** dialog box, and then click **OK**. If you do not specify an output pattern, the break occurs for any output.

If you want to set automatic commands that are executed if the event breaks into the debugger, select the event and then click **Commands**. The **Filter Command** dialog box will appear. Enter any commands that you want into the **Command** or **Second-chance Command** box. Separate multiple commands by using semicolons and do not enclose these commands in quotation marks.

## Additional Information

For more information about break status and handling status, all event codes, the default status for all events, and other methods of controlling this status, see [Controlling Exceptions and Events](#).

[Send comments about this topic to Microsoft](#)

# Debug | Modules

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Modules** on the **Debug** menu to display the current list of loaded modules.

## Dialog Box

When you click **Modules**, the **Module List** dialog box appears. This dialog box lists all modules that are currently loaded into memory.

**Module List** is divided into the following columns:

- The **Name** column specifies the module name.
- The **Start** and **End** columns specify the first and last address of the module's memory image.
- The **Timestamp** column specifies the build date and time for the module.
- The **Checksum** column specifies the checksum value.
- The **Symbols** column displays information about the symbols that this module uses. For more information about the values that appear in this column, see [Symbol Status Abbreviations](#).
- The **Symbol file** column specifies the path and file name of the associated symbol file. If the debugger is unaware of any symbol file, the name of the executable file is given instead.

If you click the title bar of a column, the display is sorted by the data in that column. If you click the title bar again, the sort order reverses.

If you select a line and then click **Reload**, that module's symbol information is reloaded.

If you select a line and press CTRL+C, the whole line is copied to the clipboard.

Click **Close** to close this dialog box.

[Send comments about this topic to Microsoft](#)

# Debug | Kernel Connection | Cycle Baud Rate

5/26/2017 • 1 min to read • [Edit Online](#)

Point to **Kernel Connection** and then click **Cycle Baud Rate** on the **Debug** menu to change the baud rate that is used in the kernel debugging connection.

This command is equivalent to pressing CTRL+ALT+A. (You can also press CTRL+A in KD.)

This command cycles through all available baud rates for the kernel debugging connection. Supported baud rates are 19200, 38400, 57600, and 115200. Every time that you use this command, the next baud rate is selected. If the baud rate is already at 115200, it is reduced to 19200.

You cannot use this command to change the baud rate at which you are debugging. The baud rate of the host computer and the target computer must match, and you cannot change the baud rate of the target computer without restarting the computer. Therefore, you must change the baud rate only if the two computers are trying to communicate at different rates. In this case, you must change the host computer's baud rate to match that of the target computer.

[Send comments about this topic to Microsoft](#)

# Debug | Kernel Connection | Cycle Initial Break

5/26/2017 • 1 min to read • [Edit Online](#)

Point to **Kernel Connection** and then click **Cycle Initial Break** on the **Debug** menu to change the conditions on which the debugger automatically breaks into the target computer.

This command is equivalent to pressing CTRL+ALT+K. (You can also press CTRL+K in KD.)

This command causes the kernel debugger to cycle through the following three states:

## **No break**

The debugger does not break into the target computer unless you press **CTRL+BREAK** or **Debug | Break**.

## **Break on reboot**

The debugger breaks into a restarted target computer after the kernel initializes. This command is equivalent to starting WinDbg with the **-b command-line option**.

## **Break on first module load**

The debugger breaks into a restarted target computer after the first kernel module is loaded. (This action causes the break to occur earlier than in the **Break on reboot** state.) This command is equivalent to starting WinDbg with the **-d command-line option**.

When you use the **Cycle Initial Break** command, the new break state is displayed.

## **Additional Information**

For more information about related commands and an explanation of how the restart process affects the debugger, see [Crashing and Rebooting the Target Computer](#).

[Send comments about this topic to Microsoft](#)

# Debug | Kernel Connection | Resynchronize

5/26/2017 • 1 min to read • [Edit Online](#)

Point to **Kernel Connection** and then click **Resynchronize** on the **Debug** menu to cause the debugger to try to reestablish a kernel debugging connection with the target computer.

This command is equivalent to pressing CTRL+ALT+R. (You can also press CTRL+R in KD.)

Use this command if the target is not responding.

## Additional Information

For more information about reestablishing contact with the target, see [Synchronizing with the Target Computer](#).

[Send comments about this topic to Microsoft](#)

# Window Menu

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the following commands on the **Window** menu of WinDbg:

[Window | Close All Source Windows](#)

[Window | Close All Error Windows](#)

[Window | Open Dock](#)

[Window | Dock All](#)

[Window | Undock All](#)

**Window | Cascade Floating Windows**

**Window | Horizontally Tile Floating Windows**

**Window | Vertically Tile Floating Windows**

[Window | MDI Emulation](#)

[Window | Automatically Open Disassembly](#)

[List of Open Windows](#)

[Send comments about this topic to Microsoft](#)

# Window | Close All Source Windows

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Close All Source Windows** on the **Window** menu to close all Source windows.

[Send comments about this topic to Microsoft](#)

# Window | Close All Error Windows

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Close All Error Windows** on the **Window** menu to close all error message boxes that have opened from source files that were not found.

[Send comments about this topic to Microsoft](#)

# Window | Open Dock

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Open Dock** on the **Window** menu to create a new dock. A *dock* is an independent window that you can drag debugging information windows to. For more information about docks, see [Creating New Docks](#).

## Additional Information

For more information about docked, tabbed, and floating windows, see [Positioning the Windows](#).

[Send comments about this topic to Microsoft](#)

# Window | Dock All

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Dock All** on the **Window** menu to dock all of the floating windows, except for those with **Always floating** selected on their shortcut menus.

WinDbg automatically positions each floating window. If a window has never been docked before, WinDbg moves it to a new untabbed location. If a window has been docked before, WinDbg moves it to its most recent docking location, which might be either tabbed or untabbed.

## Additional Information

For more information about docked, tabbed, and floating windows, see [Positioning the Windows](#).

[Send comments about this topic to Microsoft](#)

# Window | Undock All

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Undock All** on the **Window** menu to change all of the docked windows to floating windows.

WinDbg returns each docked window to the position that it occupied the last time that it was a floating window.

## Additional Information

For more information about docked, tabbed, and floating windows, see [Positioning the Windows](#).

[Send comments about this topic to Microsoft](#)

# Window | MDI Emulation

5/26/2017 • 1 min to read • [Edit Online](#)

Select **MDI Emulation** on the **Window** menu to cause WinDbg to emulate the Multiple Document Interface (MDI) style of windowing. This kind of windowing differs from docking mode because all windows are floating, but floating windows are constrained within the frame window. This behavior emulates the behavior of WinDbg before docking mode was introduced.

Clear **MDI Emulation** on the **Window** menu to return WinDbg to docking mode.

## Additional Information

For more information about docked, tabbed, and floating windows, see [Positioning the Windows](#).

[Send comments about this topic to Microsoft](#)

# Window | Automatically Open Disassembly

5/26/2017 • 1 min to read • [Edit Online](#)

Select **Automatically Open Disassembly** on the **Window** menu to cause the [Disassembly window](#) to open every time WinDbg begins a debugging session.

If you clear this command, you can still open the Disassembly window by clicking **Disassembly** on the **View** menu, pressing ALT+7, or clicking the **Disassembly (Alt+F7)** button () on the toolbar.

[Send comments about this topic to Microsoft](#)

# List of Open Windows

5/26/2017 • 1 min to read • [Edit Online](#)

At the bottom of the **Window** menu, there is a list of all currently open debugging information windows. Click any window from this list to open the window.

[Send comments about this topic to Microsoft](#)

# Help Menu

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes the following commands on the **Help** menu of WinDbg:

[Help | Contents](#)

[Help | Window](#)

[Help | Selection](#)

[Help | Index](#)

[Help | Search](#)

[Help | About](#)

[Send comments about this topic to Microsoft](#)

# Help | Contents

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Contents** on the **Help** menu to open the **Contents** tab in this Help documentation.

This command is equivalent to pressing F1.

## Additional Information

For more information about how to use this Help file, see [Using the Help File](#).

[Send comments about this topic to Microsoft](#)

# Help | Index

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Index** on the **Help** menu to open the **Index** tab in this Help documentation.

## Additional Information

For more information about how to use this Help file, see [Using the Help File](#).

[Send comments about this topic to Microsoft](#)

# Help | Search

5/26/2017 • 1 min to read • [Edit Online](#)

Click **Search** on the **Help** menu to open the **Search** tab in this Help documentation.

## Additional Information

For more information about how to use this Help file, see [Using the Help File](#).

[Send comments about this topic to Microsoft](#)

# Help | About

5/26/2017 • 1 min to read • [Edit Online](#)

Click **About** on the **Help** menu to open a message box that shows the version information for the WinDbg binaries that you are using.

Click **OK** to close this message box.

[Send comments about this topic to Microsoft](#)

# Toolbar Buttons

5/26/2017 • 2 min to read • [Edit Online](#)

Except for the breakpoint button, each button on the toolbar is equivalent to a menu command. For a full description of each button's effects, see the page for the corresponding menu command.

The buttons on the toolbar have the following effects.

| BUTTON | DESCRIPTION                                                                                                                                                                                                                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | Opens a source file as a read-only file. Equivalent to <a href="#">File   Open Source File</a> .                                                                                                                                                                                                               |
|        | Removes the selected text from the active window and puts it on the clipboard. Equivalent to <a href="#">Edit   Cut</a> .                                                                                                                                                                                      |
|        | Copies the selected text from the active window to the clipboard. Equivalent to <a href="#">Edit   Copy</a> .                                                                                                                                                                                                  |
|        | Pastes the text on the clipboard to where the cursor is located. Equivalent to <a href="#">Edit   Paste</a> .                                                                                                                                                                                                  |
|        | Starts or resumes execution. Execution continues until a breakpoint is reached, an exception or event occurs, the process ends, or the debugger breaks into the target. Equivalent to <a href="#">Debug   Go</a> .                                                                                             |
|        | Restarts execution at the beginning of the process. Equivalent to <a href="#">Debug   Restart</a> .                                                                                                                                                                                                            |
|        | Stops execution and terminates the target process permanently. Equivalent to <a href="#">Debug   Stop Debugging</a> .                                                                                                                                                                                          |
|        | In user mode, this button stops the process and its threads. In kernel mode, this button breaks into the target computer. Control is returned to the debugger. This button is also useful for cutting off long <a href="#">Debugger Command window</a> displays. Equivalent to <a href="#">Debug   Break</a> . |
|        | Executes a single instruction. If the instruction is a function call, the debugger steps into the function. Equivalent to <a href="#">Debug   Step Into</a> .                                                                                                                                                  |
|        | Executes a single instruction. If the instruction is a function call, the debugger executes the whole function in one step. Equivalent to <a href="#">Debug   Step Over</a> .                                                                                                                                  |

| BUTTON | DESCRIPTION                                                                                                                                                                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        | Executes the rest of the current function, and breaks when the function return is completed. Equivalent to <a href="#">Debug   Step Out</a> .                                                                                                                                                                             |
|        | Executes all instructions from the current instruction up to the instruction marked in the active Disassembly window or Source window. Equivalent to <a href="#">Debug   Run to Cursor</a> .                                                                                                                              |
|        | <p><b>If the active window is a Source or Disassembly window:</b> Inserts a breakpoint at the current line. (If there already is a breakpoint set at the current line, this button removes the breakpoint.)</p> <p><b>Otherwise:</b> Opens the <b>Breakpoints</b> dialog box like <a href="#">Edit   Breakpoints</a>.</p> |
|        | Opens or activates the <b>Debugger Command</b> window. Equivalent to <a href="#">View   Command</a> .                                                                                                                                                                                                                     |
|        | Opens or activates the <b>Watch</b> window. Equivalent to <a href="#">View   Watch</a> .                                                                                                                                                                                                                                  |
|        | Opens or activates the <b>Locals</b> window. Equivalent to <a href="#">View   Locals</a> .                                                                                                                                                                                                                                |
|        | Opens or activates the <b>Registers</b> window. Equivalent to <a href="#">View   Registers</a> .                                                                                                                                                                                                                          |
|        | Opens a new <b>Memory</b> window. Equivalent to <a href="#">View   Memory</a> .                                                                                                                                                                                                                                           |
|        | Opens or activates the <b>Calls</b> window. Equivalent to <a href="#">View   Call Stack</a> .                                                                                                                                                                                                                             |
|        | Opens or activates the <b>Disassembly</b> window. Equivalent to <a href="#">View   Disassembly</a> .                                                                                                                                                                                                                      |
|        | Opens or activates the <b>Scratch Pad</b> . Equivalent to <a href="#">View   Scratch Pad</a> .                                                                                                                                                                                                                            |
|        | Switches between source-mode and assembly-mode debugging. Equivalent to selecting or clearing <a href="#">Debug   Source Mode</a> .                                                                                                                                                                                       |

| BUTTON                                                                                           | DESCRIPTION                                                                                                                   |
|--------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
|  A <sub>A</sub> | Enables you to change the font that is used in the debugging information windows. Equivalent to <a href="#">View   Font</a> . |
|  A              | Displays the <b>Options</b> dialog box. Equivalent to <a href="#">View   Options</a> .                                        |

# Keyboard Shortcuts

5/26/2017 • 4 min to read • [Edit Online](#)

You can use the following keyboard shortcuts to switch between windows. For more information about how to move between the windows, see [Positioning the Windows](#).

| KEYS     | EFFECT                                                                                                                                                                                                                                  |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CTRL+TAB | Switches between debugging information windows. By using this key repeatedly, you can scan through all of the windows, regardless of whether they are floating, docked by themselves, or part of a tabbed collection of docked windows. |
| ALT+TAB  | Switches between the windows that are currently on your desktop. You can also use this keyboard shortcut to switch between the WinDbg frame and any additional docks you have created.                                                  |

You can use the following keyboard shortcuts instead of the mouse to select menu commands. For more information about each command, see the individual command topics.

| KEYS          | MENU EQUIVALENT                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------|
| F1            | <a href="#">Help   Contents</a>                                                                     |
| F3            | <a href="#">Edit   Find Next</a>                                                                    |
| SHIFT+F3      | Same as <a href="#">Edit   Find Next</a> , except the search is performed in the reverse direction. |
| ALT+F4        | <a href="#">File   Exit</a>                                                                         |
| CTRL+F4       | <a href="#">File   Close Current Window</a>                                                         |
| F5            | <a href="#">Debug   Go</a>                                                                          |
| SHIFT+F5      | <a href="#">Debug   Stop Debugging</a>                                                              |
| CTRL+SHIFT+F5 | <a href="#">Debug   Restart</a>                                                                     |
| F6            | <a href="#">File   Attach to a Process</a>                                                          |

| KEYS        | MENU EQUIVALENT                                                                                                                                                                                                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F7          | <a href="#">Debug   Run to Cursor</a>                                                                                                                                                                                                                                                                           |
| F8          | <a href="#">Debug   Step Into</a>                                                                                                                                                                                                                                                                               |
| F9          | <p>If the active window is a Source or Disassembly window:<br/>Inserts a breakpoint at the current line. (If there already is a breakpoint set at the current line, this button removes the breakpoint.)</p> <p>Otherwise: Opens the <b>Breakpoints</b> dialog box like <a href="#">Edit   Breakpoints</a>.</p> |
| ALT+F9      | <a href="#">Edit   Breakpoints</a>                                                                                                                                                                                                                                                                              |
| F10         | <a href="#">Debug   Step Over</a>                                                                                                                                                                                                                                                                               |
| CTRL+F10    | <a href="#">Debug   Run to Cursor</a>                                                                                                                                                                                                                                                                           |
| F11         | <a href="#">Debug   Step Into</a>                                                                                                                                                                                                                                                                               |

| ALT+DEL               | <a href="#">Debug   Break</a>                    |

The following shortcut keys are equivalent to KD / CDB control keys.

| KEYS       | MENU EQUIVALENT                                             | KD / CDB CONTROL KEY |
|------------|-------------------------------------------------------------|----------------------|
| CTRL+ALT+A | <a href="#">Debug   Kernel Connection   Cycle Baud Rate</a> | CTRL+A               |

| KEYS       | MENU EQUIVALENT                                                 | KD / CDB CONTROL KEY                       |
|------------|-----------------------------------------------------------------|--------------------------------------------|
| CTRL+ALT+D |                                                                 | <a href="#">CTRL+D (Toggle Debug Info)</a> |
| CTRL+ALT+K | <a href="#">Debug   Kernel Connection   Cycle Initial Break</a> | CTRL+K                                     |
| CTRL+ALT+R | <a href="#">Debug   Kernel Connection   Resynchronize</a>       | CTRL+R                                     |
| CTRL+ALT+V | <a href="#">View   Verbose Output</a>                           | CTRL+V                                     |
| CTRL+ALT+W | <a href="#">View   Show Version</a>                             | CTRL+W                                     |

You can use the following keyboard shortcuts to move the caret (^) in most of the debugging information windows.

| CARET MOVEMENT                | KEY        |
|-------------------------------|------------|
| One character left            | LEFT       |
| One character right           | RIGHT      |
| Word left                     | CTRL+LEFT  |
| Word right                    | CTRL+RIGHT |
| Line up                       | UP         |
| Line down                     | DOWN       |
| Page up                       | PAGE UP    |
| Page down                     | PAGE DOWN  |
| Beginning of the current line | HOME       |
| End of the line               | END        |
| Beginning of the file         | CTRL+HOME  |

| CARET MOVEMENT  | KEY      |
|-----------------|----------|
| End of the file | CTRL+END |

**Note** In the [Debugger Command window](#), the UP and DOWN keys browse through the command history. You can use the INSERT key to turn insert mode on and off.

Use the following keyboard shortcuts to select text.

| SELECT                       | KEYS                                   |
|------------------------------|----------------------------------------|
| Character to the left        | SHIFT+LEFT                             |
| Character to the right       | SHIFT+RIGHT                            |
| Word to the left             | SHIFT+CTRL+LEFT                        |
| Word to the right            | SHIFT+CTRL+RIGHT                       |
| Current line                 | SHIFT+DOWN if the caret is in column 1 |
| Line above                   | SHIFT+UP if the caret is in column 1   |
| To the end of the line       | SHIFT+END                              |
| To the beginning of the line | SHIFT+HOME                             |
| Screen up                    | SHIFT+PAGE UP                          |
| Screen down                  | SHIFT+PAGE DOWN                        |
| To beginning of file         | SHIFT+CTRL+HOME                        |
| To end of file               | SHIFT+CTRL+END                         |
