 - If you specified NTSD with the -ddefer and -server options, NTSD is launched without a console window. You can then connect to the debugging session by using both a kernel debugger and a user-mode remote debugger, running on a different computer than the service (but possibly the same computer as each other). For instructions, see [Combining This Method with Remote Debugging](#).
5. When the debugger starts, the service pauses at the initial process breakpoint, the exception, or the **DebugBreak** command. This enables you to examine the current state of the service application, set

breakpoints, and make any other desired configuration choices.

6. Use **g (Go)** or another execution command to resume the execution of the service application.

Debugging the Service Application Manually

5/26/2017 • 1 min to read • [Edit Online](#)

Manually attaching to a service application after it has been started is much like debugging any running user-mode process.

Use [the TList tool](#) with the **/s** option to display the process ID (PID) of each running process and the services active in each process.

If the service application you want to debug is combined with other services in a single process, you must isolate it before debugging it. To do this, perform the procedure described in [Isolating the Service](#). At the end of this procedure, restart the service.

To determine the new PID of the service, issue the following Service Configuration tool (Sc.exe) command, where *ServiceName* is the name of the service:

```
sc queryex ServiceName
```

Now start WinDbg or CDB with this service application as the target. There are three ways to do this: by specifying the PID with the **-p** option, by specifying the executable name with the **-pn** option (if the executable name is unique), or by specifying the service name with the **-psn** option.

For example, if the process SpoolSv.exe has a PID of 651 and contains the service named *Spooler*, the following three commands are equivalent:

```
windbg -p 651 [AdditionalOptions]
windbg -pn spoolsv.exe [AdditionalOptions]
windbg -psn spooler [AdditionalOptions]
```

After the debugger starts, proceed as you would in any other user-mode debugging session.

Attaching to a Target Computer Running Hyper-V

5/26/2017 • 1 min to read • [Edit Online](#)

Windows Server 2008 Hyper-V is a virtualization platform that enables multiple operating systems to run on a single computer. Each operating system runs in an isolated virtual space known as a *partition*. The first partition, known as the *root partition* or *parent partition*, must run Windows Server 2008 or a later version of Windows. The other partitions, known as *guest partitions* or *child partitions*, may run other operating systems. Windows hypervisor, a component of Hyper-V, runs as a thin layer between these partitions and the hardware.

Debugging Tools for Windows supports kernel debugging of the root partition, as well as kernel debugging of Windows hypervisor itself. This debugging can be done across a null-modem cable or a 1394 connection.

The procedures used to perform this debugging are described in the following sections:

[Debugging Hyper-V via a Null-modem Cable Connection](#)

[Debugging Hyper-V via a 1394 Cable Connection](#)

[Troubleshooting Hyper-V Debugging](#)

[Send comments about this topic to Microsoft](#)

Debugging Hyper-V via a Null-modem Cable Connection

5/26/2017 • 3 min to read • [Edit Online](#)

To debug either the root partition or Windows hypervisor across a null-modem cable connection, use the following procedure.

1. Verify that you have the proper version of Debugging Tools for Windows installed on the host computer. If you are unsure of which version to use, see [Choosing a 32-Bit or 64-Bit Debugger Package](#). To debug Hyper-V across a null-modem cable, the x64 package must be used. If a different version of the package is required for your target, use a 1394 cable to debug Hyper-V,
2. Copy the file Kdhvcom.dll from the Debugging Tools for Windows package to the Windows\system32 directory on the root partition of the target computer.
3. On the target computer, use the BCDEdit tool to set the boot configuration settings to allow the debugging that you want. If you intend to debug the root partition, use the following commands:

```
bcdedit /set dbgtransport kdhvcom.dll
bcdedit /dbgsettings serial DEBUGPORT:Port BAUDRATE:Baud
bcdedit /debug on
```

If you intend to debug Windows hypervisor, use the following commands:

```
bcdedit /hypervisorsettings serial DEBUGPORT:Port BAUDRATE:Baud
bcdedit /set hypervisordebug on
bcdedit /set hypervisorlauchtype auto
```

In these commands, *Port* represents the number of the COM port that you are using, and *Baud* represents the rate of the connection. For example, if you are using COM1 with a baud of 115,200, *Port* is **1** and *Baud* is **115200**. For details on the use of BCDEdit, see [Editing Boot Options](#).

If you want to enable debugging of both the root partition and Window hypervisor, use both sets of BCDEdit commands described in this step.

After issuing these BCDEdit commands, restart the target computer.

4. Connect the host computer and the target computer by connecting a null-modem cable between their COM ports. This is done exactly as in standard kernel debugging; for details, see [Setting Up a Null-Modem Cable Connection](#).
5. Open a Command Prompt window on the host computer, and change the current directory to the root directory of the Debugging Tools for Windows installation. Run the vmdemux (virtual machine demultiplexer) tool, using the following command line:

```
vmdemux -src com:port=Port,baud=Baud
```

In this command, *Port* represents the number of the COM port you are using (including the "com" prefix), and *Baud* represents the rate of the connection. For example, if you are using COM1 with a baud of 115,200, *Port* is **com1** and *Baud* is **115200**. If you have already begun debugging Windows hypervisor and are

restarting vmdemux, include the -channel 0 parameter as well.

Vmdemux creates multiple named-pipe sessions across the COM connection: one channel for debugging Windows hypervisor and one channel for debugging the root partition. For each channel, vmdemux displays a connection string that can be used to connect a kernel debugger across that channel.

6. The actual debugging session is started by using the Remote tool (Remote.exe) to launch KD. To begin debugging the root partition, use the following command:

```
remote.exe /s "DbgPath\kd -k RPConnectionString -y SymPath" HyperV_ROOT
```

To begin debugging Windows hypervisor, use the following command:

```
remote.exe /s "DbgPath\kd -k HVConnectionString -y SymPath" HyperV_HV
```

In these commands, *RPConnectionString* and *HVConnectionString* represent the connection strings for the root partition and Windows hypervisor, respectively, which were displayed in the output of vmdemux in the previous step. *DbgPath* represents the root directory of the Debugging Tools for Windows installation, and *SymPath* represents the symbol path. You may include other KD options as well. If you want to connect remotely to KD from another computer (using WinDbg or a second instance of KD), include the **-server** parameter followed by any permissible transport options. If you include the **-server** parameter, it must be the first parameter used.

For example, the command to debug the root partition is similar to this:

```
remote.exe /s "\debuggers\kd -k com:port=\\.\\pipe\\Vm1,pipe, resets=0, reconnect -y
srv*c:\\localstore*https://msdl.microsoft.com/download/symbols" HyperV_ROOT
```

And the command to debug Windows hypervisor is similar to this:

```
remote.exe /s "c:\\debuggers\\kd -k com:port=\\.\\pipe\\Vm0,pipe, resets=0, reconnect -y
srv*c:\\localstore*https://msdl.microsoft.com/download/symbols" HyperV_HV
```

At this point, you can debug the target normally.

[Send comments about this topic to Microsoft](#)

Debugging Hyper-V via a 1394 Cable Connection

5/26/2017 • 2 min to read • [Edit Online](#)

To debug the root partition or Windows hypervisor across a 1394 cable connection, use the following procedure.

1. Verify that you have the proper version of Debugging Tools for Windows installed on the host computer. If you are unsure of which version to use, see [Choosing a 32-Bit or 64-Bit Debugger Package](#).
2. On the target computer, use the BCDEdit tool to set the boot configuration settings to allow the debugging that you want. If you intend to debug the root partition, use the following commands:

```
bcdedit /set dbgtransport kd1394.dll
bcdedit /dbgsettings 1394 CHANNEL:ChannelNumber
bcdedit /debug on
```

If you intend to debug Windows hypervisor, use the following commands:

```
bcdedit /hypervisorsettings 1394 CHANNEL:ChannelNumber
bcdedit /set hypervisordebug on
bcdedit /set hypervisorlauchtype auto
```

In these commands, *ChannelNumber* represents the number of the 1394 channel that you are using. For details on the use of BCDEdit, see [Editing Boot Options](#).

If you want to enable debugging of both the root partition and Window hypervisor, use both sets of BCDEdit commands described in this step, with two different 1394 channel numbers.

After issuing these BCDEdit commands, restart the target computer.

3. Connect the host computer and the target computer by connecting a null-modem cable between their COM ports. This is done exactly as in standard kernel debugging; for details, see [Setting Up a 1394 Cable Connection](#).
4. The actual debugging session is started by using the Remote tool (Remote.exe) to launch KD. To begin debugging, use the following command:

```
remote.exe /s "DbgPath\kd -k 1394:channel=ChannelNumber -y SymPath" RemoteID
```

In this command, *ChannelNumber* represents the 1394 channel number you used in the BCDEdit command. To debug the root partition, use the channel number you specified for it; to debug Windows hypervisor, use the channel number you specified for it. *RemoteID* represents an identifying string that is used by the Remote tool (for example, **HyperV_ROOT** or **HyperV_HV**). *DbgPath* represents the root directory of the Debugging Tools for Windows installation, and *SymPath* represents the symbol path. You may include other KD options as well. If you want to connect remotely to KD from another computer, (using WinDbg or a second instance of KD), include the **-server** parameter followed by any permissible transport options. If you include the **-server** parameter, it must be the first parameter used.

For example, the command to debug the root partition is similar to this:

```
remote.exe /s "\debuggers\kd -k 1394:channel=50 -y  
srv*c:\localstore*https://msdl.microsoft.com/download/symbols" HyperV_ROOT
```

At this point, you can debug the target normally.

Troubleshooting Hyper-V Debugging

5/26/2017 • 1 min to read • [Edit Online](#)

This section discusses some problems that can arise during Hyper-V debugging.

Cabling and Configuration Problems

If there is no connection string when the root partition starts up, this is usually caused by a cabling or configuration issue. For example, output such as the following might be displayed:

```
Waiting to reconnect...
Connected to Windows 6001 x64 target, ptr64 TRUE
Kernel Debugger connection established.
Symbol search path is: c:\mysymbols\
Executable search path is:
Loading symbols for fffff800`01602000  ntkrnlmp.exe ->  ntkrnlmp.exe
ModLoad: fffff800`01602000 fffff800`01b17000  ntkrnlmp.exe
Windows Kernel Version 6001 MP (1 procs) Free x64
```

To address this problem, check the configuration of the root partition by typing **bcdedit** at a command prompt, and verify that the values are correct.

Vmdemux Problems

If you restart vmdemux (virtual machine demultiplexer) after you have begun debugging Windows hypervisor, you must add -channel 0 to its command-line options in order to have the hypervisor channel re-created. This is typically done automatically by Windows hypervisor, but in this case it is not possible, because Windows hypervisor is already being debugged.

For a full list of the VMDemux command-line options, type vmdemux -? at the command prompt.

Problems with Unmodified Partitions

If you have already set up Hyper-V debugging across a null-modem cable, and have copied the Kdhvcom.dll file to the root partition, and then you later restart the target computer in another partition that does not have this file installed, the debugger may freeze. In this case, restart vmdemux. This problem arises because unmodified partitions cannot handle multiplexed traffic. Typically, vmdemux closes down all the pipes on a clean shutdown. However, a non-clean shutdown, such as doing a hard restart, is not detectable.

Symbols for Windows debugging (WinDbg, KD, CDB, NTSD)

5/26/2017 • 1 min to read • [Edit Online](#)

Symbols for the Windows debuggers (WinDbg, KD, CDB, and NTSD) are available from a public symbol server. You can also download entire symbol packages.

This section includes:

[Introduction to Symbols](#)

[Accessing Symbols for Debugging](#)

[How the Debugger Recognizes Symbols](#)

[Symbol Problems While Debugging](#)

These topics explain what symbols are, how to access them during a debugging session, how to control the debugger's symbol options and symbol matching, and how to respond to various symbol-related problems during debugging.

If you simply want to configure your debugger to access symbols for your own programs and for Windows, you may find it quicker to read the less-detailed introductory topics [Symbol Path](#) and [Using a Symbol Server](#).

[Send comments about this topic to Microsoft](#)

Introduction to Symbols

5/26/2017 • 1 min to read • [Edit Online](#)

This section includes:

[Symbols and Symbol Files](#)

[Public and Private Symbols](#)

[Send comments about this topic to Microsoft](#)

Symbol path for Windows debuggers

5/31/2017 • 6 min to read • [Edit Online](#)

The symbol path specifies locations where the Windows debuggers (WinDbg, KD, CDB, NTST) look for symbol files. For more information about symbols and symbol files, see [Symbols](#).

Some compilers (such as Microsoft Visual Studio) put symbol files in the same directory as the binary files. The symbol files and the checked binary files contain path and file name information. This information frequently enables the debugger to find the symbol files automatically. If you are debugging a user-mode process on the computer where the executable was built, and if the symbol files are still in their original location, the debugger can locate the symbol files without you setting the symbol path.

In most other situations, you have to set the symbol path to point to your symbol file locations.

Symbol Path Syntax

The debugger's symbol path is a string that consists of multiple directory paths, separated by semicolons.

Relative paths are supported. However, unless you always start the debugger from the same directory, you should add a drive letter or a network share before each path. Network shares are also supported.

For each directory in the symbol path, the debugger looks in three directories. For example, if the symbol path includes the c:\MyDir directory, and the debugger is looking for symbol information for a DLL, the debugger first looks in c:\MyDir\symbols\dll, then in c:\MyDir\dll, and finally in c:\MyDir. The debugger then repeats this process for each directory in the symbol path. Finally, the debugger looks in the current directory and then in the current directory with \dll appended to it. (The debugger appends \dll, \exe, or \sys, depending on which binaries it is debugging.)

Symbol files have date and time stamps. You do not have to worry that the debugger will use the wrong symbols that it may find first in this sequence. It always looks for the symbols that match the time stamp on the binary files that it is debugging. For more information about responses when symbols files are not available, see [Compensating for Symbol-Matching Problems](#).

One way to set the symbol path is by entering the **.sympath** command. For other ways to set the symbol path, see [Controlling the Symbol Path](#) later in this topic.

Caching Symbols Locally

We strongly recommend that you always cache your symbols locally. One way to cache symbols locally is to include **cache***; or **cache\localsymbolcache*** in your symbol path.

If you include the string **cache***; in your symbol path, symbols loaded from any element that appears to the right of this string are stored in the default symbol cache directory on the local computer. For example, the following command tells the debugger to get symbols from the network share \\someshare and cache the symbols in the default location on the local computer.

```
.sympath cache*;\\someshare
```

If you include the string **cache\localsymbolcache*** in your symbol path, symbols loaded from any element that appears to the right of this string are stored in the *localsymbolcache* directory.

For example, the following command tells the debugger to obtain symbols from the network share \\someshare

and cache the symbols in the c:\MySymbols directory.

```
.sympath cache*c:\MySymbols;\someshare
```

Using a Symbol Server

If you are connected to the Internet or a corporate network, the most efficient way to access symbols is to use a symbol server. You can use a symbol server by using the **srv\ **srv\symbolstore, or **srv\localsymbolcache**symbolstore** string in your symbol path.

If you include the string **srv*** in your symbol path, the debugger uses a symbol server to get symbols from the default symbol store. For example, the following command tells the debugger to use a symbol server to get symbols from the default symbol store. These symbols are not cached on the local computer.

```
.sympath srv*
```

If you include the string **srv*symbolstore** in your symbol path, the debugger uses a symbol server to get symbols from the *symbolstore* store. For example, the following command tells the debugger to use a symbol server to get symbols from the symbol store at <https://msdl.microsoft.com/download/symbols>. These symbols are not cached on the local computer.

```
.sympath srv*https://msdl.microsoft.com/download/symbols
```

If you include the string **srv\localcache**symbolstore** in your symbol path, the debugger uses a symbol server to get symbols from the *symbolstore* store and caches them in the *localcache* directory. For example, the following command tells the debugger to use a symbol server to get symbols from the symbol store at <https://msdl.microsoft.com/download/symbols> and cache the symbols in c:\MyServerSymbols.

```
.sympath srv*c:\MyServerSymbols*https://msdl.microsoft.com/download/symbols
```

If you have a directory on your computer where you manually place symbols, do not use that directory as the cache for symbols obtained from a symbol server. Instead, use two separate directories. For example, you can manually place symbols in c:\MyRegularSymbols and then designate c:\MyServerSymbols as a cache for symbols obtained from a server. The following example shows how to specify both directories in your symbol path.

```
.sympath c:\MyRegularSymbols;srv*c:\MyServerSymbols*https://msdl.microsoft.com/download/symbols
```

For more information about symbol servers, see [Symbol Stores and Symbol Servers](#).

Combining cache* and srv*

If you include the string **cache***; in your symbol path, symbols loaded from any element that appears to the right of this string are stored in the default symbol cache directory on the local computer. For example, the following command tells the debugger to use a symbol server to get symbols from the store at <https://msdl.microsoft.com/download/symbols> and cache them in the default symbol cache directory.

```
.sympath cache*;srv*https://msdl.microsoft.com/download/symbols
```

If you include the string **cache\localsymbolcache,*** in your symbol path, symbols loaded from any element

that appears to the right of this string are stored in the *localsymbolcache* directory.

For example, the following command tells the debugger to use a symbol server to get symbols from the store at <https://msdl.microsoft.com/download/symbols> and cache the symbols in the c:\MySymbols directory.

```
.sympath cache*c:\MySymbols;srv*https://msdl.microsoft.com/download/symbols
```

Using AgeStore to Reduce the Cache Size

You can use the AgeStore tool to delete cached files that are older than a specified date, or to delete enough old files that the resulting size of the cache is less than a specified amount. This can be useful if your downstream store is too large. For details, see [AgeStore](#).

For more information about symbol servers and symbol stores, see [Symbol Stores and Symbol Servers](#).

Lazy Symbol Loading

The debugger's default behavior is to use *lazy symbol loading* (also known as *deferred symbol loading*). This kind of loading means that symbols are not loaded until they are required.

When the symbol path is changed, for example by using the [.sympath](#) command, all loaded modules with export symbols are lazily reloaded.

Symbols of modules with full PDB symbols will be lazily reloaded if the new path no longer includes the original path that was used to load the PDB symbols. If the new path still includes the original path to the PDB symbol file, those symbols will not be lazily reloaded.

For more information about lazy symbol loading, see [Deferred Symbol Loading](#).

You can turn off lazy symbol loading in CDB and KD by using the [-s](#) command-line option. You can also force symbol loading by using the [!ld \(Load Symbols\)](#) command or by using the [.reload \(Reload Module\)](#) command together with the [/f](#) option.

Controlling the Symbol Path

To control the symbol path, you can do one of the following:

- Use the [.sympath](#) command to display, set, change, or append to the path. The [.symfix \(Set Symbol Store Path\)](#) command is similar to [.sympath](#) but saves you some typing.
- Before you start the debugger, use the [_NT_SYMBOL_PATH](#) and [_NT_ALT_SYMBOL_PATH](#) environment variables to set the path. The symbol path is created by appending [_NT_SYMBOL_PATH](#) after [_NT_ALT_SYMBOL_PATH](#). (Typically, the path is set through the [_NT_SYMBOL_PATH](#). However, you might want to use [_NT_ALT_SYMBOL_PATH](#) to override these settings in special cases, such as if you have private versions of shared symbol files.) If you try to add an invalid directory through these environment variables, the debugger ignores this directory.
- When you start the debugger, use the [-y](#) command-line option to set the path.
- (WinDbg only) Use the [File | Symbol File Path](#) command or press **CTRL+S** to display, set, change, or append to the path.

If you use the [-sins](#) command-line option, the debugger ignores the symbol path environment variable.

Symbols and Symbol Files

5/26/2017 • 1 min to read • [Edit Online](#)

When applications, libraries, drivers, or operating systems are linked, the linker that creates the .exe and .dll files also creates a number of additional files known as *symbol files*.

Symbol files hold a variety of data which are not actually needed when running the binaries, but which could be very useful in the debugging process.

Typically, symbol files might contain:

- Global variables
- Local variables
- Function names and the addresses of their entry points
- Frame pointer omission (FPO) records
- Source-line numbers

Each of these items is called, individually, a *symbol*. For example, a single symbol file Myprogram.pdb might contain several hundred symbols, including global variables and function names and hundreds of local variables. Often, software companies release two versions of each symbol file: a full symbol file containing both *public symbols* and *private symbols*, and a reduced (stripped) file containing only public symbols. For details, see [Public and Private Symbols](#).

When debugging, you must make sure that the debugger can access the symbol files that are associated with the target you are debugging. Both live debugging and debugging crash dump files require symbols. You must obtain the proper symbols for the code that you wish to debug, and load these symbols into the debugger.

Windows Symbols

Windows keeps its symbols in files with the extension .pdb.

The compiler and the linker control the symbol format. The Visual C++ linker, places all symbols into .pdb files.

The Windows operating system is built in two versions. The *free build* (or *retail build*) has relatively small binaries, and the *checked build* (or *debug build*) has larger binaries, with more debugging symbols in the code itself. Each of these builds has its own symbol files. When debugging a target on Windows, you must use the symbol files that match the build of Windows on the target.

The following table lists several of the directories which exist in a standard Windows symbol tree:

DIRECTORY	CONTAINS SYMBOL FILES FOR
ACM	Microsoft Audio Compression Manager files
COM	Executable files (.com)
CPL	Control Panel programs

DIRECTORY	CONTAINS SYMBOL FILES FOR
DLL	Dynamic-link library files (.dll)
DRV	Driver files (.drv)
EXE	Executable files (.exe)
SCR	Screen-saver files
SYS	Driver files (.sys)

[Send comments about this topic to Microsoft](#)

Public and Private Symbols

5/31/2017 • 8 min to read • [Edit Online](#)

When a full-sized .pdb or .dbg symbol file is built by a linker, it contains two distinct collections of information: the *private symbol data* and a *public symbol table*. These collections differ in the list of items they contain and the information they store about each item.

The private symbol data includes the following items:

- Functions
- Global variables
- Local variables
- Information about user-defined structures, classes, and data types
- The name of the source file and the line number in that file corresponding to each binary instruction

The public symbol table contains fewer items:

- Functions (except for functions declared **static**)
- Global variables specified as **extern** (and any other global variables visible across multiple object files)

As a general rule, the public symbol table contains exactly those items that are accessible from one source file to another. Items visible in only one object file--such as **static** functions, variables that are global only within a single source file, and local variables--are not included in the public symbol table.

These two collections of data also differ in what information they include for each item. The following information is typically included for each item contained in the private symbol data:

- Name of the item
- Address of the item in virtual memory
- Frame pointer omission (FPO) records for each function
- Data type of each variable, structure, and function
- Types and names of the parameters for each function
- Scope of each local variable
- Symbols associated with each line in each source file

On the other hand, the public symbol table stores only the following information about each item included in it:

- The name of the item.
- The address of the item in the virtual memory space of its module. For a function, this is the address of its entry point.
- Frame pointer omission (FPO) records for each function.

In other words, the public symbol data can be thought of as a subset of the private symbol data in two ways: it contains a shorter list of items, and it also contains less information about each item. For example, the public symbol data does not include local variables at all. Each local variable is included only in the private symbol data,

with its address, data type, and scope. Functions, on the other hand, are included both in the private symbol data and public symbol table, but while the private symbol data includes the function name, address, FPO records, input parameter names and types, and output type, the public symbol table includes just the function name, address, and FPO record.

There is one other difference between the private symbol data and the public symbol table. Many of the items in the public symbol table have names that are *decorated* with a prefix, a suffix, or both. These decorations are added by the C compiler, the C++ compiler, and the MASM assembler. Typical prefixes include a series of underscores or the string `_imp_` (designating an imported function). Typical suffixes include one or more at signs (@) followed by addresses or other identifying strings. These decorations are used by the linker to disambiguate the symbol, since it is possible that function names or global variable names could be repeated across different modules. These decorations are an exception to the general rule that the public symbol table is a subset of the private symbol data.

Full Symbol Files and Stripped Symbol Files

A *full symbol file* contains both the private symbol data and the public symbol table. This kind of file is sometimes referred to as a *private symbol file*, but this name is misleading, for such a file contains both private and public symbols.

A *stripped symbol file* is a smaller file that contains only the public symbol table - or, in some cases, only a subset of the public symbol table. This file is sometimes referred to as a *public symbol file*.

Creating Full and Stripped Symbol Files

If you build your binaries with Visual Studio, you can create either full or stripped symbol files. When building a "debug build" of a binary, Visual Studio typically will create full symbol files. When building a "retail build", Visual Studio typically creates no symbol files, but a full or stripped symbol file will be created if the proper options are set.

If you build your binaries with the Build utility, the utility will create full symbol files.

Using the BinPlace tool, you can create a stripped symbol file from a full symbol file. When the most common BinPlace options are used (`-a -x -s -n`), the stripped symbol files are placed in the directory that is listed after the `-s` switch, and the full symbol files are placed in the directory that is listed after the `-n` switch. When BinPlace strips a symbol file, the stripped and full versions of the file are given identical signatures and other identifying information. This allows you to use either version for debugging.

Using the PDBCopy tool, you can create a stripped symbol file from a full symbol file by removing the private symbol data. PDBCopy can also remove a specified subset of the public symbol table. For details, see [PDBCopy](#).

Using the SymChk tool, you can determine whether a symbol file contains private symbols. For details, see [SymChk](#).

Viewing Public and Private Symbols in the Debugger

You can use WinDbg, KD, or CDB to view symbols. When one of these debuggers has access to a full symbol file, it has both the information listed in the private symbol data and the information listed in the public symbol table. The private symbol data is more detailed, while the public symbol data contains symbol decorations.

When accessing private symbols, private symbol data is always used because these symbols are not included in the public symbol table. These symbols are never decorated.

When accessing public symbols, the debugger's behavior depends on certain [symbol options](#):

- When the `SYMOPT_UNDNAME` option is on, decorations are not included when the name of a public symbol is displayed. Moreover, when searching for symbols, decorations are ignored. When this option is off, decorations are displayed when displaying public symbols, and decorations are used in searches. Private symbols are never decorated in any circumstances. This option is on by default in all debuggers.

- When the `SYMOPT_PUBLICS_ONLY` option is on, private symbol data is ignored, and only the public symbol table is used. This option is off by default in all debuggers.
- When the `SYMOPT_NO_PUBLICS` option is on, the public symbol table is ignored, and searches and symbol information use the private symbol data alone. This option is off by default in all debuggers.
- When the `SYMOPT_AUTO_PUBLICS` option is on (and both `SYMOPT_PUBLICS_ONLY` and `SYMOPT_NO_PUBLICS` are off), the first symbol search is performed in the private symbol data. If the desired symbol is found there, the search terminates. If not, the public symbol table is searched. Since the public symbol table contains a subset of the symbols in the private data, normally this results in the public symbol table being ignored.
- When the `SYMOPT_PUBLICS_ONLY`, `SYMOPT_NO_PUBLICS`, and `SYMOPT_AUTO_PUBLICS` options are all off, both private symbol data and the public symbol table are searched each time a symbol is needed. However, when matches are found in both places, the match in the private symbol data is used. Therefore, the behavior in this instance is the same as when `SYMOPT_AUTO_PUBLICS` is on, except that using `SYMOPT_AUTO_PUBLICS` may cause symbol searches to happen slightly faster.

Here is an example in which the command **x (Examine Symbols)** is used three times. The first time, the default symbol options are used, and so the information is taken from the private symbol data. Note that this includes information about the address, size, and data type of the array **typingString**. Next, the command `.symopt+ 4000` is used, causing the debugger to ignore the private symbol data. When the **x** command is then run again, the public symbol table is used; this time there is no size and data type information for **typingString**. Finally, the command `.symopt- 2` is used, which causes the debugger to include decorations. When the **x** command is run this final time, the decorated version of the function name, **_typingString**, is shown.

```
0:000> x /t /d *!*typingstring*
00434420 char [128] TimeTest!typingString = char [128] ""

0:000> .symopt+ 4000

0:000> x /t /d *!*typingstring*
00434420 <NoType> TimeTest!typingString = <no type information>

0:000> .symopt- 2

0:000> x /t /d *!*typingstring*
00434420 <NoType> TimeTest!_typingString = <no type information>
```

Viewing Public and Private Symbols with the DBH Tool

Another way to view symbols is by using the [the DBH tool](#). DBH uses the same symbol options as the debugger. Like the debugger, DBH leaves `SYMOPT_PUBLICS_ONLY` and `SYMOPT_NO_PUBLICS` off by default, and turns `SYMOPT_UNDNAME` and `SYMOPT_AUTO_PUBLICS` on by default. These defaults can be overridden by a command-line option or by a DBH command.

Here is an example in which the DBH command **addr 414fe0** is used three times. The first time, the default symbol options are used, and so the information is taken from the private symbol data. Note that this includes information about the address, size, and data type of the function **fgets**. Next, the command `symopt +4000` is used, which causes DBH to ignore the private symbol data. When the **addr 414fe0** is then run again, the public symbol table is used; this time there is no size and data type information for the function **fgets**. Finally, the command `symopt -2` is used, which causes DBH to include decorations. When the **addr 414fe0** is run this final time, the decorated version of the function name, **_fgets**, is shown.

```
pid:4308 mod:TimeTest[400000]: addr 414fe0
```

```
fgets
  name : fgets
  addr : 414fe0
  size : 113
  flags : 0
  type : 7e
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagFunction (5)
  index : 7d
```

```
pid:4308 mod:TimeTest[400000]: symopt +4000
```

```
Symbol Options: 0x10c13
Symbol Options: 0x14c13
```

```
pid:4308 mod:TimeTest[400000]: addr 414fe0
```

```
fgets
  name : fgets
  addr : 414fe0
  size : 0
  flags : 0
  type : 0
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagPublicSymbol (a)
  index : 7f
```

```
pid:4308 mod:TimeTest[400000]: symopt -2
```

```
Symbol Options: 0x14c13
Symbol Options: 0x14c11
```

```
pid:4308 mod:TimeTest[400000]: addr 414fe0
```

```
_fgets
  name : _fgets
  addr : 414fe0
  size : 0
  flags : 0
  type : 0
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagPublicSymbol (a)
  index : 7f
```

Accessing Symbols for Debugging

5/26/2017 • 2 min to read • [Edit Online](#)

Setting up symbols correctly for debugging can be a challenging task, particularly for kernel debugging. It often requires that you know the names and releases of all products on your computer. The debugger must be able to locate each of the symbol files corresponding to the product releases and service packs.

This can result in an extremely long symbol path consisting of a long list of directories.

To simplify these difficulties in coordinating symbol files, the symbol files can be gathered into a *symbol store*, which is then accessed by a *symbol server*.

A symbol store is a collection of symbol files, an index, and a tool that can be used by an administrator to add and delete files. The files are indexed according to unique parameters such as the time stamp and image size. A symbol store can also hold executable image files which can be extracted using a symbol server. Debugging Tools for Windows contains a symbol store creation tool called [SymStore](#).

A symbol server enables the debuggers to automatically retrieve the correct symbol files from a symbol store without the user needing to know product names, releases, or build numbers. Debugging Tools for Windows contains a symbol server called [SymSrv](#). The symbol server is activated by including a certain text string in the symbol path. Each time the debugger needs to load symbols for a newly loaded module, it calls the symbol server to locate the appropriate symbol files.

If you wish to use a different method for your symbol search than that provided by SymSrv, you can create your own symbol server DLL. For details on implementing such a symbol server, see [Other Symbol Servers](#).

If you are performing user-mode debugging, you will need symbols for the target application. If you are performing kernel-mode debugging, you will need symbols for the driver you are debugging, as well as the Windows public symbols. Microsoft has created a symbol store with public symbols for Microsoft products; this symbol store is available on the internet. These symbols can be loaded using the [.symfix \(Set Symbol Store Path\)](#) command, as long as you have access to the internet while your debugger is running. For more information or to determine how to manually install these symbols, see [Installing Windows Symbol Files](#).

This section includes:

[Installing Windows Symbol Files](#)

[Symbol Stores and Symbol Servers](#)

[Deferred Symbol Loading](#)

[Send comments about this topic to Microsoft](#)

Installing Windows Symbol Files

5/26/2017 • 3 min to read • [Edit Online](#)

Before you debug the Windows kernel or a driver or application running on Windows, you need access to the proper symbol files.

If you have access to the internet while your debugger is running, you may wish to use Microsoft's public symbol store. You can connect to this with one simple use of the [.symfix \(Set Symbol Store Path\)](#) command. For full details, see [Microsoft Public Symbols](#).

If you plan to install symbols manually, it is crucial that you remember this basic rule: the symbol files on the host computer are required to match the version of Windows installed on the target computer. If you are planning to do a kernel mode debug of a Windows XP target from a Windows 2000 host, you need to install the Windows XP symbol files on the Windows 2000 system. If you plan to perform user-mode debugging on the same computer as the target application, then install the symbol files that match the version of Windows running on that system. If you are analyzing a memory dump file, then the version of symbol files needed on the debug computer are those that match the version of the operating system that produced the dump file, not necessarily those matching the version of the operating system on the machine running the debug session.

Note If you are going to use your host computer to debug several different target computers, you may need symbols for more than one build of Windows. In this case, be sure to install each symbol collection in a distinct directory path.

If you are debugging from a Windows computer attached to a network, it may be useful to install symbols for a variety of different builds on a network server. Microsoft debuggers will accept a network path (`\server\share\dir`) as a valid symbol directory path. This avoids the need for each debugging computer on the network to install the symbol files separately.

Symbol files stored on a crashed target computer are not usable by the debugger on the host computer.

To install symbol files for Windows XP or later

1. Make sure you have at least 1000 MB of available space on the disk drive of the host computer.
2. Open the [Windows Symbols](#) Web site in your internet browser.
3. Follow the links to download the appropriate symbol package.

To install symbol files for Windows 2000 from the Web

1. Make sure you have at least 1000 MB of available space on the disk drive of the host computer.
2. Open the [Windows Symbols](#) Web site in your internet browser.
3. Follow the links to download Windows 2000 symbols.

To install symbol files for Windows 2000 from the Support CD

1. Make sure you have at least 500 MB of available space on the disk drive of the host computer.
2. Insert the Windows 2000 Customer Support Diagnostics CD.
3. Click **Install Symbols**.
4. Select either **Install Retail Symbols** (free build) or **Install Debug Symbols** (checked build). The symbols must match the version of the operating system being debugged.

5. Enter the path where the symbols are to be stored, or accept the default path. The default path is %windir%\symbols.

Sequence of Symbol File Installation

If you intend to keep your symbols in a single directory tree, the installation sequence of symbol files should mirror the installation sequence of operating system files:

To install the symbol files in correct sequence

1. Install the operating system symbol files.
2. Install the symbol files for the currently installed Service Pack (if any).
3. Install the symbol files for any Hot Fixes that were installed after the current Service Pack was installed (if any).

However, a superior setup would be to install the symbols from each Service Pack and Hot Fix in a separate directory tree, and put all these directories in your symbol search path. The debugger will then find the proper symbols. (Since the symbol files have date and time stamps, the debugger will be able to tell which are the most recent.) See [Symbol Path](#) for details.

Installing User-Mode Symbols

If you are going to debug a user-mode application, you need to install the symbols for this application as well.

You can debug an application if you have its symbols but not Windows symbols. However, your results will be much more limited. You will still be able to step through the application code, but any debugger activity which requires analysis of the kernel (such as getting a stack trace) is likely to fail.

Symbol Stores and Symbol Servers

5/26/2017 • 1 min to read • [Edit Online](#)

A *symbol store* is a collection of symbol files, an index, and a tool for adding and deleting files. A symbol store may also contain executable image files. The debugger accesses the files in a symbol store by using a *symbol server*. Debugging Tools for Windows includes both a symbol store creation tool, [SymStore](#), and a symbol server, [SymSrv](#). It also includes a tool, [SymProxy](#), for setting up an HTTP symbol store on a network to serve as a proxy for all symbol stores that the debugger may need to access.

This section includes:

[SymSrv](#)

[Using a Symbol Server](#)

[HTTP Symbol Stores](#)

[File Share \(SMB\) Symbol Server](#)

[SymStore](#)

[SymProxy](#)

[SymStore](#)

If you are not setting up your own symbol store, but just intend to use the public Microsoft symbol store, see [Microsoft Public Symbols](#).

[Send comments about this topic to Microsoft](#)

Using a Symbol Server

5/26/2017 • 1 min to read • [Edit Online](#)

A symbol server enables the debugger to automatically retrieve the correct symbol files from a symbol store - an indexed collection of symbol files - without the user needing to know product names, releases, or build numbers. The Debugging Tools for Windows package includes the symbol server [SymSrv](#) (symsrv.exe).

Using SymSrv with a Debugger

SymSrv can be used with WinDbg, KD, NTSD, or CDB.

To use this symbol server with the debugger, simply include the text **srv*** in the symbol path. For example:

```
set _NT_SYMBOL_PATH = srv*DownstreamStore*SymbolStoreLocation
```

where *DownstreamStore* specifies the local directory or network share that will be used to cache individual symbol files, and *SymbolStoreLocation* is the location of the symbol store either in the form `\server\share` or as an internet address. For more syntax options, see [Advanced SymSrv Use](#).

Microsoft has a Web site that makes Windows symbols publicly available. You can refer directly to this site in your symbol path in the following manner:

```
set _NT_SYMBOL_PATH=srv*DownstreamStore*https://msdl.microsoft.com/download/symbols
```

where, again, *DownstreamStore* specifies the local directory or network share that will be used to cache individual symbol files. For more information, see [Microsoft Public Symbols](#).

If you plan to create a symbol store, configure a symbol store for web (HTTP) access, or write your own symbol server or symbol store, see [Symbol Stores and Symbol Servers](#).

Using AgeStore to Reduce the Cache Size

Any symbol files downloaded by SymSrv will remain on your hard drive after the debugging session is over. To control the size of the symbol cache, the AgeStore tool can be used to delete cached files that are older than a specified date, or to reduce the contents of the cache below a specified size. For details, see [AgeStore](#).

[Send comments about this topic to Microsoft](#)

SymSrv

5/26/2017 • 1 min to read • [Edit Online](#)

SymSrv (symsrv.dll) is a symbol server that is included in the Debugging Tools for Windows package.

Many users of Debugging Tools for Windows use the public symbol store on the Microsoft Web site to access symbols for Microsoft products. If this is your goal, you only need to read the first topic listed below.

This section includes:

[Microsoft Public Symbols](#)

[Advanced SymSrv Use](#)

[Firewalls and Proxy Servers](#)

[Send comments about this topic to Microsoft](#)

Microsoft public symbol server

5/31/2017 • 1 min to read • [Edit Online](#)

The Microsoft symbol server makes Windows debugger symbols publicly available.

You can refer directly to the public symbol server in your symbol path in the following manner:

```
set _NT_SYMBOL_PATH=srv*DownstreamStore*https://msdl.microsoft.com/download/symbols
```

DownstreamStore must specify a directory on your local computer or network that will be used to cache symbols. This downstream store holds symbols that the debugger has accessed; the vast majority of symbols that have never been accessed remain on the symbol store at Microsoft. This keeps your downstream store relatively small and allows the symbol server to work quickly, only downloading each file once.

To avoid typing this long symbol path, use the [.symfix \(Set Symbol Store Path\)](#) command. The following command appends the public symbol store to your existing symbol path:

```
.symfix+ DownstreamStore
```

Note To successfully access Microsoft's public symbol store, you will need a fast internet connection. If your internet connection is only 56 Kbps or slower, you should install Windows symbols directly onto your hard drive. For details, see [Installing Windows Symbol Files](#).

For more information about the public symbol store, see the [Windows Symbols](#) Web site.

Symbol File Compression

The Microsoft Symbol Server provides compressed versions of the symbol files. The files have an underscore at the end of the filename's extension to indicate that they are compressed. For example, the PDB for ntdll.dll is available as ntdll.pd_. When SymProxy downloads a compressed file, it will store the file decompressed in the local file system. The DontUncompress registry key can be set to disable this behavior in SymProxy.

Refer to the Debugger topic [SymStore](#) for information on using SymStore.exe /compress to store your own symbols compressed on your symbol server.

[Send comments about this topic to Microsoft](#)

Advanced SymSrv Use

5/31/2017 • 10 min to read • [Edit Online](#)

SymSrv can deliver symbol files from a centralized symbol store. This store can contain any number of symbol files, corresponding to any number of programs or operating systems. The store can also contain binary files (this is useful when debugging minidumps).

The store can contain the actual symbol and binary files, or it can simply contain pointers to symbol files. If the store contains pointers, SymSrv will retrieve the actual files directly from their sources.

SymSrv can also be used to separate a large symbol store into a smaller subset that is appropriate for a specialized debugging task.

Finally, SymSrv can obtain symbol files from an HTTP or HTTPS source using the logon information provided by the operating system. SymSrv supports HTTPS sites protected by smartcards, certificates, and regular logins and passwords. For more information, see [HTTP Symbol Stores](#).

Setting the Symbol Path

To use this symbol server, `symsrv.dll` must be installed in the same directory as the debugger. The symbol path can be set as shown here:

```
set _NT_SYMBOL_PATH = symsrv*ServerDLL*DownstreamStore*\Server\Share
set _NT_SYMBOL_PATH = symsrv*ServerDLL*\Server\Share
set _NT_SYMBOL_PATH = srv*DownstreamStore*\Server\Share
set _NT_SYMBOL_PATH = srv*\Server\Share
```

The parts of this syntax are explained as follows:

symsrv

This keyword must always appear first. It indicates to the debugger that this item is a symbol server, not just a normal symbol directory.

ServerDLL

Specifies the name of the symbol server DLL. If you are using the SymSrv symbol server, this will always be `symsrv.dll`.

srv

This is shorthand for **symsrv*symsrv.dll**.

DownstreamStore

Specifies the downstream store. This is a local directory or network share that will be used to cache individual symbol files.

You can specify more than one downstream store, separated by asterisks. Multiple downstream stores are explained in **Cascading Downstream Stores** further down on this page.

If you include two asterisks in a row where a downstream store would normally be specified, then the default downstream store is used. This store will be located in the `sym` subdirectory of the home directory. The home directory defaults to the debugger installation directory; this can be changed by using the **!homedir** extension or by setting the `DBGHELP_HOMEDIR` environment variable.

If *DownstreamStore* specifies a directory that does not exist, SymStore will attempt to create it.

If the *DownstreamStore* parameter is omitted and no extra asterisk is included -- in other words, if you use **srv** with exactly one asterisk or **symsrv** with exactly two asterisks -- then no downstream store will be created. The debugger will load all symbol files directly from the server, without caching them locally.

Note If you are accessing symbols from an HTTP or HTTPS site, or if the symbol store uses compressed files, a downstream store is always used. If no downstream store is specified, one will be created in the sym subdirectory of the home directory.

\Server\Share

Specifies the server and share of the remote symbol store.

If a downstream store is used, the debugger will first look for a symbol file in this store. If the symbol file is not found, the debugger will locate the symbol file from the specified *Server* and *Share*, and then cache a copy of this file in the downstream store. The file will be copied to a subdirectory in the tree under *DownstreamStore* which corresponds to its location in the tree under **\Server\Share**.

The symbol server does not have to be the only entry in the symbol path. If the symbol path consists of multiple entries, the debugger checks each entry for the needed symbol files, in order (from left to right), regardless of whether a symbol server or an actual directory is named.

Here are some examples. To use SymSrv as the symbol server with a symbol store on **\mybuilds\mysymbols**, set the following symbol path:

```
set _NT_SYMBOL_PATH= symsrv*symsrv.dll*\mybuilds\mysymbols
```

To set the symbol path so that the debugger will copy symbol files from a symbol store on **\mybuilds\mysymbols** to your local directory **c:\localsymbols**, use:

```
set _NT_SYMBOL_PATH=symsrv*symsrv.dll*c:\localsymbols*\mybuilds\mysymbols
```

To set the symbol path so that the debugger will copy symbol files from the HTTP site www.company.com/manysymbols to a local network directory **\localserver\myshare\mycache**, use:

```
set _NT_SYMBOL_PATH=symsrv*symsrv.dll*\localserver\myshare\mycache*http://www.company.com/manysymbols
```

This last example can also be shortened as such:

```
set _NT_SYMBOL_PATH=srv*\localserver\myshare\mycache*http://www.company.com/manysymbols
```

In addition, the symbol path can contain several directories or symbol servers, separated by semicolons. This allows you to locate symbols from multiple locations (or even multiple symbol servers). If a binary has a mismatched symbol file, the debugger cannot locate it using the symbol server because it checks only for the exact parameters. However, the debugger may find a mismatched symbol file with the correct name, using the traditional symbol path, and successfully load it. Even though the file is technically not the correct symbol file, it might provide useful information.

Compressed Files

SymSrv is compatible with symbol stores that contain compressed files, as long as this compression has been done with the compress.exe tool, which is available [here](#). Compressed files should have an underscore as the last character in their file extensions (for example, module1.pd_ or module2.db_). For details, see [SymStore](#).

If the files on the store are compressed, you must use a downstream store. SymSrv will uncompress all files before

caching them on the downstream store.

Deleting the Cache

If you are using a *DownstreamStore* as a cache, you can delete this directory at any time to save disk space.

It is possible to have a vast symbol store that includes symbol files for many different programs or Windows versions. If you upgrade the version of Windows used on your target computer, the cached symbol files will all match the earlier version. These cached files will not be of any further use, and therefore this might be a good time to delete the cache.

Cascading Downstream Stores

You can specify any number of downstream stores, separated by asterisks. These stores are known as *cascading symbol stores*.

After the initial **srv*** or **symsrv\ServerDLL****, each subsequent token represents a symbol location. The token furthest left is checked first. An empty token -- indicated by two asterisks in a row, or by an asterisk at the end of the string -- represents the default downstream store.

Here is an example of a symbol path that uses two downstream stores to hold information from the main symbol store being accessed. These could be called the master store, the mid-level store, and the local cache:

```
srv*c:\localcache*\\\interim\store*https://msdl.microsoft.com/download/symbols
```

In this scenario, SymSrv will first look in `c:\localcache` for a symbol file. If it is found there, it will return a path to it. If it is not found there, it will look in `\\interim\store`. If the symbol file is found there, SymSrv will copy it to `c:\localcache` and return the path. If it is not found there, SymSrv will look in the [Microsoft public symbol store](https://msdl.microsoft.com/download/symbols) at <https://msdl.microsoft.com/download/symbols>; if the file is found there, SymSrv will copy it to both `\\interim\store` and `c:\localcache`.

A similar behavior would be obtained by using the following path:

```
srv**\\interim\store*http://internetsite
```

In this case, the local cache is the default downstream store and the master store is an internet site. A mid-level store of `\\interim\store` has been specified for use in between the other two.

When SymSrv processes a path that contains cascading stores, it will skip any store that it cannot read or write to. So if a share goes down, it will copy the file to the store downstream from the missing store without any error. A nice side effect of this error is that the user can specify more than one master store that feeds a single stream of downstream stores as long as the master stores are not writable.

When a compressed symbol file is retrieved from the master store, it will be stored in compressed form in any mid-level store. The file will be uncompressed in the bottom-most store in the path.

Working With HTTP and SMB Symbol Server Paths

As previously discussed, chaining (or cascading) refers to the copy that occurs between each `"**"` separator in the symbol path. The symbols are searched for in a left-to-right order. On each miss, the next (upstream) symbol server is queried, until the file is found.

If found, the file is copied from the (upstream) symbol server to the previous (downstream) symbol server. This is repeated for each (downstream) symbol server. In this way, the (shared) downstream symbol servers are populated with the collective efforts of all clients using the symbol servers.

Even though chained UNC paths can be used without the SRV* prefix, we recommend that SRV* be specified so that the advanced error handling of symsrv.dll be used.

When including a HTTP symbol server in the path, only one can be specified (per chain), and it must be at the end of the path (as it can't be written to serve as a cache). If an HTTP-based symbol store was located in the middle or the left of the store list, it would not be possible to copy any found files to it and the chain would be broken. Furthermore, because the symbol handler cannot open a file from a web site, an HTTP-based store should not be the leftmost or only store on the list. If SymSrv is ever presented with this symbol path, it will attempt to recover by copying the file to the default downstream store and open it from there, regardless of whether the default downstream store is indicated in the symbol path or not.

HTTP is only supported when using the SRV* prefix (implemented by the symsrv.dll symbol handler).

Example HTTP and SMB Share Symbol Server Scenarios

A common UNC-only deployment involves a central office hosting all of the files (\MainOffice\Symbols), branch offices caching a subset (\BranchOfficeA\Symbols), and desktops (C:\Symbols) caching the files that they reference.

```
srv*C:\Symbols*\BranchOfficeA\Symbols*\MainOffice\Symbols
```

When the SMB share is the primary (upstream) symbol store, Read is required.

```
srv*C:\Symbols*\MachineName\Symbols
```

When the SMB share is an intermediate (downstream) symbol store, Read/Change is required. The client will copy the file from the primary symbol store to the SMB share, and then from the SMB share to the local folder.

```
srv*C:\Symbols*\MachineName\Symbols*https://msdl.microsoft.com/download/symbols
srv*C:\Symbols*\MachineName\Symbols*\MainOffice\Symbols
```

When the SMB share is an intermediate (downstream) symbol store in a SymProxy deployment, only Read is required. The SymProxy ISAPI Filter will perform the writes, not the client.

```
srv*C:\Symbols*\MachineName\Symbols*https://SymProxyName/Symbols
```

Multiple HTTP and SMB Share Symbol Server Cache Scenarios

It is possible to specify multiple chains of symbol servers and cache locations, separated by a semi colon ;. If the symbols are located in the first chain, the second chain is not traversed. If the symbols are not located in the first chain, the second chain will be traversed and if the symbols are located in the second chain, they will be cached in the specified location. This approach will allow a primary symbol server to normally be used, with a secondary server only being used, if the symbols are not available on the primary symbol server specified in the first chain.

```
srv*C:\Symbols*\Machine1\Symbols*http://SymProxyName/Symbols;srv*C:\WebSymbols*
https://msdl.microsoft.com/download/symbols
```

cache*localsymbolcache

Another way to create a local cache of symbols is by using the **cache*localsymbolcache** string in your symbol path. This is not part of the symbol server element, but a separate element in your symbol path. The debugger will use the specified directory *localsymbolcache* to store any symbols loaded from any element that appears in your symbol path to the right of this string. This allows you to use a local cache for symbols downloaded from any location, not just those downloaded by a symbol server.

For example, the following symbol path will not cache symbols taken from \\someshare. It will use c:\mysymbols

to cache symbols taken from *anothershare*, because the element beginning with *anothershare* appears to the right of the **cache*c:\mysymbols** element. It will also use c:\mysymbols to cache symbols taken from the Microsoft public symbol store, because of the usual syntax used by the symbol server (**srv** with two or more asterisks). Moreover, if you subsequently use the **.sympath+** command to add additional locations to this path, these new elements will also be cached, since they will be appended to the right side of the path.

```
_NT_SYMBOL_PATH=\\someshare\\that\\cachestar\\ignores;srv*c:\\mysymbols*https://msdl.microsoft.com/download/symbols;cache*c:\\mysymbols;\\anothershare\\that\\gets\\cached
```

How SymSrv Locates Files

SymSrv creates a fully qualified UNC path to the desired symbol file. This path begins with the path to the symbol store recorded in the _NT_SYMBOL_PATH environment variable. The **SymbolServer** routine is then used to identify the name of the desired file; this name is appended to the path as a directory name. Another directory name, consisting of the concatenation of the *id*, *two*, and *three* parameters passed to **SymbolServer**, is then appended. If any of these values is zero, they are omitted.

The resulting directory is searched for the symbol file, or a symbol store pointer file.

If this search is successful, **SymbolServer** passes the path to the caller and returns **TRUE**. If the file is not found, **SymbolServer** returns **FALSE**.

Using AgeStore to Reduce the Cache Size

The AgeStore tool can be used to delete cached files that are older than a specified date, or to reduce the contents of the cache below a specified size. This can be useful if your downstream store is too large. For details, see [AgeStore](#).

[Send comments about this topic to Microsoft](#)

Firewalls and Proxy Servers

5/26/2017 • 2 min to read • [Edit Online](#)

If you are using SymSrv to access symbols, and your computer is on a network that uses a proxy server or the symbol store is outside your firewall, authentication may be required for data transmission to take place.

When SymSrv receives authentication requests, the debugger can either display the authentication request or automatically refuse the request, depending on how it has been configured.

SymSrv has integrated support for a proxy server. It can either use the default proxy server, [SymProxy](#), or it can use another proxy server of your choice.

Authentication Requests

The debugger can be configured to allow authentication requests. When a firewall or proxy server requests authorization, a dialog box will appear. You will have to enter some sort of information (usually a user name and password) before the debugger can download symbols. If you enter incorrect information, the dialog box will be redisplayed. If you select the **Cancel** button, the dialog box will vanish and no symbol information will be transferred.

If the debugger is configured to refuse all authentication requests, no dialog box will appear, and no symbols will be transferred if authentication is required.

If you refuse an authentication request, or if the debugger automatically refuses an authentication request, SymSrv will make no further attempts to contact the symbol store. If you wish to renew contact, you must either restart the debugging session or use [!symsrv close](#).

Note If you are using KD or CDB, the authentication dialog box may appear behind an open window. If this occurs, you may have to move or minimize some windows in order to find this dialog box.

In WinDbg, authentication requests are allowed by default. In KD and CDB, authentication requests are automatically refused by default.

To allow authentication requests, use either [!sym prompts](#) or [.symopt-0x80000](#). To refuse all requests, use either [!sym prompts off](#) or [.symopt+0x80000](#). To display the current setting, use [!sym](#).

You must use [.reload \(Reload Module\)](#) after making any changes to the authentication permission status.

Choosing a Proxy Server

To select a default proxy server for Windows, open **Internet Options** in Control Panel, select the **Connections** tab, and then select the **LAN Settings** button. You can then enter the proxy server name and port number, or select **Advanced** to configure multiple proxy servers. For more details, see Internet Explorer's help file.

To select a specific proxy server for symsrv to use, set the `_NT_SYMBOL_PROXY` environment variable equal to the name or IP of the proxy server, followed by a colon and then the port number. For example:

```
set _NT_SYMBOL_PROXY=myproxyserver:80
```

When a proxy server is chosen in this way, it will be used by any Windows debugger that is using SymSrv to access a symbol server. It will also be used by any other debugging tool that uses DbgHelp as its symbol handler. No other programs will be affected by this setting.

HTTP Symbol Stores

5/31/2017 • 5 min to read • [Edit Online](#)

By using the SRV protocol supported through symsrv.dll (shipped with debugger), the symbol store can be accessed using HTTP (instead of just UNC/SMB).

HTTP is commonly used instead of SMB when a firewall doesn't allow SMB between the client and the server. Production and Lab environments are good examples of this.

An HTTP symbol server can't be a downstream store in a symbol path chain due to its read-only nature. Symbol Server Proxy (ISAPI Filter) works around this limit. SymProxy downloads the missing files to the server's file system using preconfigured upstream symbol stores. The filter downloads the file to the file system, allowing IIS to download the file to the client, thereby restoring the concept of symbol store chaining. Refer to [SymProxy](#) for more information.

Configuring IIS as a symbol store is relatively easy as the symbol files are just served as static files. The only non-default setting is the configuration of the MIME Types to allow the download of the symbol files as binary streams. This can be done by using a "*" wildcard applied to the virtual directory of the symbol folder.

In order to make a symbol store accessible over the Internet, you must configure both the directories containing the symbol files and Internet Information Services (IIS).

Note Because of the way IIS will be configured to serve symbol files, it is not recommended that the same server instance be used for any other purpose. Typically the desired security settings for a symbol server will not make sense for other uses, for example for an external facing commerce server. Make sure that the sample configuration described here makes sense for your environment and adapt it as appropriate for your specific needs.

Creating the Symbol Directory

Begin by selecting the directory you will use as your symbol store. In our examples, we call this directory c:\symstore and the name of the server on the network is \SymMachineName.

For details on how to populate your symbol store, see [SymStore](#) and [Symbol Store Folder Tree](#).

Configuring IIS

Internet Information Services (IIS) must be configured to serve the symbols by creating a virtual directory and configuring MIME types. After this has been done, the authentication method may be chosen.

To create a virtual directory

1. From **Administrative Tools** open **Internet Information Services (IIS) Manager**.
2. Navigate to **Web Sites**.
3. Right-click **Default Web Site** or the name of the site being used and select **Add Virtual Directory...**.
4. Type **Symbols** for **Alias** and click **Next**.

For ease of administration, it's recommended that the same name be used for the Folder, Share and Virtual Directory.

5. For the **Path** enter **c:\SymStore** and click **Next**.
6. Click **OK** to finish the adding the virtual directory.

Perform the subdirectory configuration process once for the server. Note that this is a global setting and will effect

applications not hosted in the root folder of a site.

Subdirectory Configuration

1. Navigate to **[Computer]**.
2. Open the **Configuration Editor**.
3. Navigate to **system ApplicationHost/sites**.
4. Expand **virtualDirectoryDefaults**.
5. Set **allowSubDirConfig** to *False*.

Perform this process once for the server. Note that this is a global setting and will effect applications not hosted in the root folder of a site.

Optional Make the Symbol Files Browseable

1. Navigate to **[Computer] | Sites | [Web Site] | Symbols**.
2. Double click **Directory Browsing** in the center pane.
3. Click **Enable** in the right pane.

The MIME Type for the downloaded content needs to be set to application/octet-stream to allow all symbols files to be delivered by IIS.

Configuring MIME types

1. Right-click the **Symbols** virtual directory and choose **Properties**.
2. Select **HTTP Headers**.
3. Click **MIME Types**.
4. Click **New**.
5. For **Extension**, type *****.
6. For **MIME type**, type **application/octet-stream**.
7. To exit the **MIME Types** dialog box, click **OK**.
8. To exit **Symbols Properties**, click **OK**.

You can edit the web.config file to configure MIME types for Symbols. This approach clears the inherited MIME Types and adds a catch-all wild card * MIME Type. This approach may be necessary when MIME types are being inherited in certain IIS configurations.

Using web.config to configure MIME types

1. Edit the web.config file as shown here.

```
<?xml version="1.0" encoding="UTF-8"?>
<configuration>
  <system.webServer>
    <directoryBrowse enabled="true" />
    <staticContent>
      <clear />
      <mimeMap fileExtension=".*"
        mimeType="application/octet-stream" />
    </staticContent>
  </system.webServer>
</configuration>
```

2. Restart IIS.

IIS is now ready to serve symbol files of all types from the symbol store.

Configuring Authentication

It is possible to configure IIS to use “Integrated Windows Authentication” so that clients (windbg.exe for example) can automatically authenticate against IIS without prompting the end-user for credentials.

Note Only configure Windows Authentication on IIS to control access to the symbol server if that is appropriate for your environment. There are other security options available to further control access to IIS if that is required for your environment.

To configure the authentication method as Anonymous

1. Launch the **Internet Information Services (IIS) Manager**.
2. Navigate to **[Computer] | Sites | [Web Site] | Symbols**.
3. Double click **Authentication** in the center pane.
4. Under **Authentication and access control** click **Edit**.
5. Right click **Windows Authentication** and select **Enable**.
6. For all other authentication providers, right click each provider and select **Disable**.
7. Click **OK** to finish configuring authentication.

If Window Authentication is not listed, use **Turn Windows features on and off** to enable the feature. The location of the feature is different in each version of Windows. In Windows 8.1/Windows 2012 R2, it is located under Internet Information Services | World Wide Web Services | Security.

Disable Kerberos Support

SymSrv.dll does not support Kerberos authentication when connecting to IIS. As such, Kerberos authentication must be disabled in IIS and NTLM needs to be set as the only Windows Authentication protocol.

Note Only disable Kerberos security if that is appropriate for your environment.

Disable Kerberos Support Using appcmd.exe

1. Open a Command Prompt window
2. To disable Kerberos and force the use of NTLM, use this command:

```
appcmd.exe set config -section:system.webServer/security/authentication/windowsAuthentication
/+"providers.[value='NTLM']" /commit:apphost
```

3. To return to the default value with Kerberos enabled, use this command:

```
appcmd.exe set config -section:system.webServer/security/authentication/windowsAuthentication  
/+"providers.[value='Negotiate,NTLM']" /commit:apphost
```

Configuring SymSrv Client Authentication Prompts

When SymSrv receives authentication requests, the debugger can either display the authentication dialog box or automatically refuse the request, depending on how it has been configured. You can configure this behavior using !sym prompts on|off. For example to turn prompts on, use this command.

```
!sym prompts on
```

To check the current setting, use this command.

```
!sym prompts
```

For more information see [!sym](#) and [Firewalls and Proxy Servers](#) on MSDN.

[Send comments about this topic to Microsoft](#)

File Share (SMB) Symbol Server

5/31/2017 • 2 min to read • [Edit Online](#)

Running a SMB Symbol Server is simply a matter of creating a file share and granting users access to that file share.

Creating a SMB File Share Symbol Store

Use Windows Explorer or Computer Management to create the File Share and assign security. These steps assume that the symbols will be located in *D:\SymStore\Symbols*. Complete these steps using Windows Explorer:

1. Open **Windows Explorer**.
2. Right-click *D:\SymStore\Symbols* and choose **Properties**.
3. Click on the **Sharing** tab.
4. Click on **Advanced Sharing...**.
5. Check *Share this folder*.
6. Click on **Permissions**.
7. Remove the *Everyone* group.
8. Using **Add...**, add the Users/Security Groups requiring access.
9. For each User/Security Group added, grant Read or Read/Change access.
10. Click on **OK** (Permissions dialog).
11. Click on **OK** (Advanced Sharing dialog).
12. Press **Close** (Properties dialog).

Complete these steps using Computer Management:

1. Type *Computer* in Window Start (resolves as This PC in Windows 8).
2. Right-click and select *Manage*.
3. Navigate to *System Tools | Shared Folders | Shares*.
4. Right-click and select **New | Share...**.
5. Press **Next** (Create a Shared Folder Wizard dialog).
6. Enter **D:\SymStore\Symbols** as the Folder Path.
7. Press **Next** twice.
8. Select **Customize permissions**.
9. Press **Custom...**.
10. Remove *Everyone*.
11. Using **Add...**, add the Users/Security Groups requiring access.
12. For each User/Security Group added, grant Read or Read/Change access.

13. Press **OK** (Customize Permissions dialog).
14. Press **Finish** twice to complete the process.

Test The SMB File Share

Configure a debugger to use this symbol path:

```
srv*C:\Symbols*\MachineName\Symbols
```

To view the location of the PDBs being referenced in the debugger, use the `lm` (list modules) command. The path to the PDBs should all begin with `C:\Symbols`. By running `!sym noisy`, and `.reload /f`, you will see extensive symbol logging of the download of the symbols and images from the `\MachineName\Symbols` file server to `C:\Symbols`.

File Share Symbol Path

There are multiples ways to configure your debugger's symbol path (.sympath) to use a File Share. The syntax of the symbol path determines if the symbol file will be cached locally or not, and where it is cached.

Direct File Share use (no local caching):

```
srv*\MachineName\Symbols
```

Local Caching of the File Share's files to a particular local folder (e.g. `c:\Symbols`):

```
srv*c:\Symbols*\MachineName\Symbols
```

Local Caching of the File Share's files to the `%DBGHELP_HOMEDIR%\Sym` folder:

```
srv**\MachineName\Symbols
```

The second `**` in the example shown above, represents the default local server cache.

If the `DBGHELP_HOMEDIR` variable is not set, `DBGHELP_HOMEDIR` defaults to the debugger executable folder (for example `C:\Program Files\Windows Kits\10.0\Debuggers\x86`) and causes caching to occur in `C:\Program Files\Windows Kits\10.0\Debuggers\x86\Sym`.

[Symbol Store Folder Tree](#)

[Send comments about this topic to Microsoft](#)

Symbol Store Folder Tree

5/31/2017 • 1 min to read • [Edit Online](#)

The symbol store backing SMB and HTTP requests is a folder tree residing on a local disk.

To keep administration simple, the sub-folder name (e.g. Symbols) can also be used as the File Share name and also the Virtual Directory name. If a new symbol store was to be added, a new sub-folder would be made under D:\SymStore, and a new File Share and Virtual Directory of that name would be made to expose the store to clients.

The folder tree's location should be chosen carefully as well as the disk's file system. The symbol store can get extremely big (terabytes) when caching files from (internal) build servers and the Internet. The folder tree should reside on a disk that is capable of a high number of reads and low number of writes. The file system can affect performance - ReFS may perform better than NTFS and should be investigated for large deployments. Equally, the networking to the server should be of sufficient speed to handle the load from the clients and also the load to the upstream symbol stores to retrieve the symbols for cache population.

Symbol Store Single-Tier or Two-Tier Structure

Normally files are placed in a single tier directory structure in which a single subdirectory exists for each filename cached. Under each filename folder, additional folders are made to store each version of the file. The tree will have this structure:

```
D:\SymStore\Symbols\ntdll.dll\...\  
D:\SymStore\Symbols\ntdll.pdb\...\  
D:\SymStore\Symbols\kernel32.dll\...\  
D:\SymStore\Symbols\kernel32.pdb\...\
```

If a large number of files are to be stored, a two-tier structure can be used at the root of the symbol store. The first 2 letters of the filename are used as an intermediate folder name.

To use a two-tier structure, place a file called index2.txt in the root of D:\SymStore\Symbols. The content of the file is of no importance. When this file exists, symsrv.dll will create and consume files from the two-tier tree using this structure:

```
D:\SymStore\Symbols\nt\ntdll.dll\...\  
D:\SymStore\Symbols\nt\ntdll.pdb\...\  
D:\SymStore\Symbols\ke\kernel32.dll\...\  
D:\SymStore\Symbols\ke\kernel32.pdb\...\
```

If you want to convert the structure after the symbol store is populated, use the convertstore.exe application in the debugger folder. To allow the tool to work, create a folder called 000Admin in the root folder. This folder is required by convertstore.exe so that it can control the locking of the symbol store.

[File Share \(SMB\) Symbol Server](#)

[Send comments about this topic to Microsoft](#)

SymProxy

5/26/2017 • 2 min to read • [Edit Online](#)

You can configure your HTTP-based symbol store to act as a proxy between client computers and other symbol stores. The implementation is through an Internet Server Application Programming Interface (ISAPI) filter called SymProxy (Symproxy.dll). The SymProxy server can be used as a gateway computer to the Internet or other sources within your company network. The following diagram shows an example SymProxy configuration.

SymProxy is useful in many situations. For example:

- You are debugging many systems within a lab environment in which the computers are not attached to the company network, but the symbols are stored in the network and must be accessed using Integrated Windows Authentication (IWA).
- Your corporate computing environment includes a firewall that prevents access to the Internet from computers that are debugging and you must obtain symbols from an internet Web site.
- You want to present a single symbol path for all users in your company so that they need not know or care about where symbols are located, and you can add new symbol stores without user intervention.
- You have a remote site that is physically far from the rest of your company resources, and network access is slow. This system can be used to acquire symbols and cache them to the remote site.

To install SymProxy, you must manually copy the files to the correct location, configure the registry, choose network security credentials, and configure Internet Information Services (IIS). To ensure that your HTTP symbol store is properly configured, see [HTTP Symbol Stores](#).

Multiple Symbol Server Performance Considerations

Each Virtual Directory can be associated with multiple (upstream) symbol stores. Each symbol store is queried independently. For performance, local SMB servers should be processed before internet HTTP servers. Unlike a debugger symbol path, multiple HTTP symbol stores can be specified in a SymProxy symbol path. A maximum of 10 entries are supported per Virtual Directory.

SymProxy Symbol Path

SymProxy splits the (registry defined) symbol path value up into the individual entries and uses each entry to generate a SRV* based symbol path to retrieve the file. It uses the Virtual Directory's folder as the downstream store in each of the queries – in effect, merging the upstream stores into a single downstream symbol store.

The (generated) symbol path used by SymProxy is equivalent to this:

```
SRV*<Virtual Directory Folder>*<SymbolPath Entry #N>
```

In this example, a UNC path and two HTTP paths are associated with a Virtual Directory to merge the symbols from a corporate symbol server, Microsoft and a 3rd party (Contoso). The SymProxy SymbolPath would be set like this:

```
\MainOffice\Symbols;https://msdl.microsoft.com/download/symbols;  
http://symbols.contoso.com/symbols
```

The Main Office Symbol file share is queried first using a (generated) symbol path of:

```
SRV*D:\SymStore\Symbols*\MainOffice\Symbols
```

If the symbol file is not found, the Microsoft Symbol Store is queried using a (generated) symbol path of:

```
SRV*D:\SymStore\Symbols*https://msdl.microsoft.com/download/symbols
```

If the file is still not found, the Contoso Symbol Store (<http://symbols.contoso.com/symbols>) is queried using a (generated) symbol path of:

```
SRV*D:\SymStore\Symbols*http://symbols.contoso.com/symbols
```

Installing SymProxy

5/26/2017 • 1 min to read • [Edit Online](#)

Summary of installation tasks

The following summarizes the tasks to install and configure SymProxy.

- The SymProxy files need to be copied to the %WINDIR%\system32\inetsrv folder for IIS. This task is discussed below.
- The registry needs to be configured for SymProxy. For more information see [Configuring the Registry](#).
- The manifest needs to be registered as Performance Counters and ETW events, and the Event Log needs to be configured.
- IIS needs to be configured. For more information, see [Choosing Network Security Credentials](#) and [Configuring IIS for SymProxy](#).
- Confirm that SymProxy is running as expected using the status page. For more information see [Checking and Updating Status](#).

These steps can be automated using the Install.cmd file. For more information, see [SymProxy Automated Installation](#).

Copy the SymProxy files to IIS

The SymProxy files are included in the Debuggers directory of the Windows Driver Kit. For example this is the location of the 64 bit files for Windows 10 kit. C:\Program Files (x86)\Windows Kits\10\Debuggers\x64\symproxy.

To install SymProxy on the server, copy symproxy.dll, symsrv.dll and symproxy.man to %WINDIR%\system32\inetsrv.

In order to prevent problems that could occur in accessing the Microsoft Symbol Store at <http://msdl.microsoft.com/downloads/symbols>, create a blank file called %WINDIR%\system32\inetsrv\symsrv.yes. The contents of this file are not important. When symsrv.yes file is present, it automatically accepts the EULA for the Microsoft Public Symbol Store.

[Send comments about this topic to Microsoft](#)

Configuring the Registry

5/31/2017 • 9 min to read • [Edit Online](#)

SymProxy stores its settings in this registry key.

```
HKLM\Software\Microsoft\Symbol Server Proxy
```

This registry key controls the location from which to find symbols to store in the Web site, the logging level, and whether or not SymProxy operates with a direct connection to the network. You can create this key by running the SymProxy registration tool (Symproxy.reg) provided with Debugging Tools for Windows. Type **symproxy.reg** at the command prompt or double-click it from Windows Explorer.

This will add entries for the settings that will be prefixed with an "x" so that they are disabled. To enable a setting, remove the "x" from in front of the desired setting.

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Symbol Server Proxy]
"Available Settings"="Remove the 'x' prefix to use the setting"
"xLogLevel"=dword:0000000f
"xNoInternetProxy"=dword:00000001
"xNoFilePointers"=dword:00000001
"xNoUncompress"=dword:00000001
"xNoCache"=dword:00000001
"xMissTimeout"=dword:00000e10
"xMissAgeTimeout"=dword:00015180
"xMissAgeCheck"=dword:00000e10
"xMissFileCache"=dword:00000001
"xMissFileThreads"=dword:00000010
"xFailureCount"=dword:00000004
"xFailurePeriod"=dword:00000078
"xFailureTimeout"=dword:00002d
"xFailureBlackout"=dword:0000384
```

The symproxy.reg registry file assumes a virtual directory name of Symbols and configures the Symbol Path to use the Microsoft Public Symbol Server.

```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Symbol Server Proxy\Web Directories]
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Symbol Server Proxy\Web Directories\Symbols]
"SymbolPath"="https://msdl.microsoft.com/download/symbols"
```

The event logging entries in symproxy.reg are covered latter in the Event Log section of this topic.

```
[HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog\Application\Microsoft-Windows-SymProxy]
"ProviderGuid"="{0876099c-a903-47ff-af14-52035bb479ef}"
"EventMessageFile"=hex(2):25,00,53,00,79,00,73,00,74,00,65,00,6d,00,52,00,6f, \
  00,6f,00,74,00,25,00,5c,00,73,00,79,00,73,00,74,00,65,00,6d,00,33,00,32,00, \
  5c,00,69,00,6e,00,65,00,74,00,73,00,72,00,76,00,5c,00,53,00,79,00,6d,00,50, \
  00,72,00,6f,00,78,00,79,00,2e,00,64,00,6c,00,6c,00,00,00,00
"TypesSupported"=dword:00000007
```

The web directory entries in symproxy.reg are discussed in this topic.

Web Directories

For each virtual directory generated in IIS that you are using as a symbol store, you must setup a registry key below the **Web Directories** subkey of the following registry key.

HKLM\Software\Microsoft\Symbol Server Proxy

To edit the registry key for a symbol store virtual directory

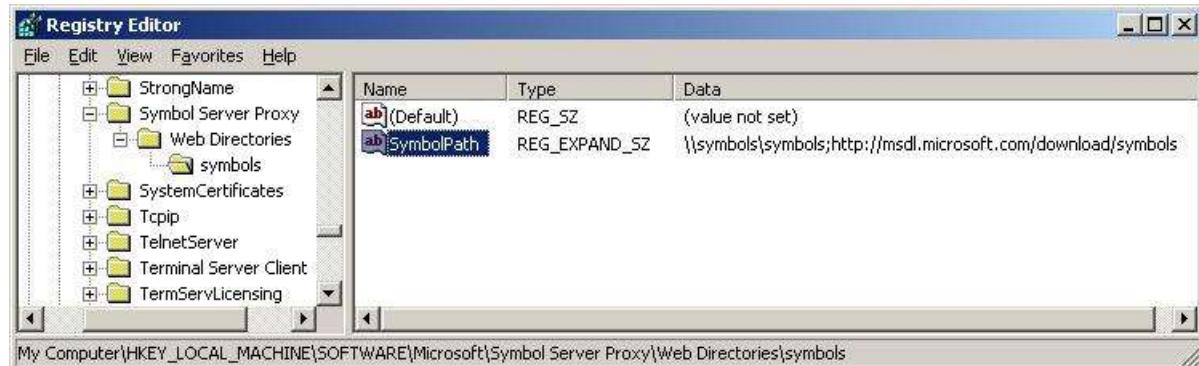

- Edit the contents of **SymbolPath** to contain all of the symbol stores used by the SymProxy symbol store. If there is more than one symbol store being used, separate them with semicolons. A maximum of 10 stores is supported for each value. HTTP paths must include the **http:// prefix**, and UNC paths must include the **** prefix.

For example, if one of the virtual directories is called Symbols, and the symbols stores that it accesses are located at the UNC store **\symbols\symbols** and the HTTP store **<https://msdl.microsoft.com/download/symbols>**, create the following registry key.

HKLM\Software\Microsoft\Symbol Server Proxy\Web Directories\Symbols

After this key is created, edit its **SymbolPath** to be

\symbols\symbols;https://msdl.microsoft.com/download/symbols. This can be seen in the following screenshot of the Registry Editor.

In this example, SymProxy first searches for symbols in **\symbols\symbols**. If the files are not found there, the Microsoft Symbol Store will be used.

- In each of the keys under Web Directories that match the Virtual Directory names, a REG_SZ called **SymbolPath** needs to be created. The value contains all the upstream symbol stores that will be used to populate the SymProxy symbol store.
- A maximum of 10 entries are supported.
- Separate entries with semicolons.
- UNC paths need to include the **** prefix
- HTTP paths need to include the **"http://" prefix**
- Order the values from least expensive to most expensive.
 - You will need to balance usage performance goals vs. server and data communications costs in the calculation.
 - In general, put local SMB/HTTP servers before internet HTTP servers.

SymProxy Performance Counters

SymProxy can emit performance counters via a provider called SymProxy.

To enable the performance counters support, register the symproxy manifest file in an administrator command window:

```
C:\> lodctr.exe /m:%WINDIR%\system32\inetsrv\symproxy.man
```

To disable the performance counters support, unregister the manifest:

```
C:\> unlodctr.exe /m:%WINDIR%\system32\inetsrv\symproxy.man
```

SymProxy Event Tracing for Windows

SymProxy can create ETW events via a provider called Microsoft-Windows-SymProxy.

```
C:\> logman query providers | findstr SymProxy
Microsoft-Windows-SymProxy {0876099C-A903-47FF-AF14-52035BB479EF}
```

To enable the ETW support, register the manifest file:

```
C:\> wevtutil.exe install-manifest %WINDIR%\system32\inetsrv\symproxy.man
```

To disable the ETW support, unregister the manifest file:

```
C:\> wevtutil.exe uninstall-manifest %WINDIR%\system32\inetsrv\symproxy.man
```

Event Log

If ETW is configured, the events are recorded as events in the *Operational and Analytic* channels under *Applications and Services Logs\Microsoft\Windows\SymProxy* in the Event Log.

To correctly view the message of the Event Log entries, the Event Log area of the symproxy.reg file needs to be added to the registry:

```
[HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog\Application\Microsoft-Windows-SymProxy]
"ProviderGuid"="{0876099C-a903-47ff-af14-52035bb479ef}"
"EventMessageFile"=hex(2):25,00,53,00,79,00,73,00,74,00,65,00,6d,00,52,00,6f,\n
00,6f,00,74,00,25,00,5c,00,73,00,79,00,73,00,74,00,65,00,6d,00,33,00,32,00,\n
5c,00,69,00,6e,00,65,00,74,00,73,00,72,00,76,00,5c,00,53,00,79,00,6d,00,50,\n
00,72,00,6f,00,78,00,79,00,2e,00,64,00,6c,00,6c,00,00,00,00
"TypesSupported"=dword:00000007
```

SymProxy Events

SymProxy logs the following events:

Event ID	Description	Channel
1	Start of the ISAPI filter	Admin
2	Stop of the ISAPI filter	Admin
3	Configuration of the ISAPI filter	Admin

4	Miss Cache Statistics	Admin
10	URL Request - Local Cache Hit	Operational
11	URL Request - Local Cache Miss	Operational
20	Symbol Download via SymSrv	Operational
30	Critical Symbol Missing	Admin
31	Critical Image Missing	Admin
40	SymSrv – Path Not Found	Admin
41	SymSrv – File Not Found	Admin
42	SymSrv – Access Denied	Admin
43	SymSrv – Path Too Long	Admin
49	SymSrv – Error Code	Admin
90	Lock Contention	Operational
100	General Critical Message	Analytic
101	General Error Message	Analytic
102	General Warning Message	Analytic
103	General Informational Message	Analytic
104	General Analytic Message	Analytic
105	General Debug Message	Debug

Symbol Server Proxy Configuration

SymProxy stores its configuration settings in the following registry key area:

HKLM/Software/Microsoft/Symbol Server Proxy

From this location, SymProxy acquires its global settings and the symbol paths of upstream symbol stores.

You can create this key by merging in the symproxy.reg file you customized as discussed earlier.

Symbol Server Proxy' key

The Symbol Server Proxy registry key supports the following global settings (all REG_DWORD). Settings can be applied live by recycling the application pool. A new w3wp.exe process will be created and it will read the new values. Once all pending requests to the old w3wp.exe process have completed, the old w3wp.exe process will end. IIS by default recycles w3wp.exe processes every 1,740 minutes (29 hours).

REG_DWORD	Description
LogLevel	<p>By default, SymProxy doesn't log an extensive amount of information about its use of SymSrv.dll. Creating REG_DWORD:"LogLevel" with a value of 5 (Analytic) or 6 (Debug), enables the additional logging.</p>
NoInternetProxy	<p>When running as a service, SymSrv.dll uses WinHTTP instead of WinInet to make HTTP requests. Consequently, you may need to set up HTTP proxy settings so that the service can access outside network resources. You can do this using the netsh program. Type "netsh.exe winhttp -?" for instructions.</p> <p>By default, SymProxy uses the designated HTTP proxy. If no HTTP proxy is configured, SymProxy will use a dummy proxy. This allows secure access to HTTP sites within your intranet. As a side effect, this prevents SymProxy from directly connecting to non-secure sites.</p> <p>Creating the REG_DWORD:"NoInternetProxy" value configures SymProxy to operate without a proxy, allowing a direct connection.</p>
NoFilePointers	<p>By default, for symbols that don't exist, SymProxy will look for a file.ptr file next to the requested file (in the local cache). If found, it will return the location specified by the file.ptr file. This ability is only required when the local cache is being populated by SymStore.exe.</p> <p>Create the REG_DWORD:"NoFilePointers" value to skip the lookup.</p>
NoUncompress	<p>By default, SymProxy will decompress downloaded symbols before returning the file to the caller. This reduces CPU at the client, but increases I/O.</p> <p>Create the REG_DWORD:"NoUncompress" value to skip the decompression.</p>
NoCache	<p>By default, SymProxy will cache downloaded symbols to the local file system, defined by the virtual directory's path.</p> <p>Create the REG_DWORD:"NoCache" value to skip the download and to provide the remote path of the file to the client instead.</p>

<p>MissTimeout</p>	<p>Timeout period, in seconds, for which missing symbols are reported as missing without re-querying the upstream symbol servers.</p> <p>A miss is associated with a UTC based time. Subsequent requests for the file are immediately rejected for N seconds.</p> <p>The first request for the file after N seconds causes the upstream symbol stores to be re-queried.</p> <p>On success, the symbol file is returned and the miss is deleted.</p> <p>On failure, the miss is moved forward to the current time (in UTC) to start a new timeout period.</p> <p>Use the "Miss Cache" counters to monitor the misses.</p> <ul style="list-style-type: none"> • Unspecified - (default) 300 seconds/5 minutes • 0 – Feature disabled • N – Timeout lasts N seconds
<p>MissAgeCheck</p>	<p>Period between Miss Age checks. The Miss cache is scanned and records older than MissAgeTimeout seconds are removed.</p> <p>The current statistics are saved to the Event Log using Event ID 4.</p> <ul style="list-style-type: none"> • Unspecified - (default) 3600 seconds / 1 hour • 0 – Feature disabled • N – Period between checks in N seconds
<p>MissFileCache</p>	<p>By default, SymProxy does not save miss information to disk. Create the REG_DWORD:"MissFileCache" value to cache miss information in the symbol folder tree. Create the REG_DWORD:"MissFileCache" value to cache miss information in the symbol folder tree.</p> <p>Enable MissFileCache when miss information needs to be shared across an IIS farm. Enabling MissFileCache also makes worker process recycling more efficient.</p> <p>MissFileCache causes an I/O operation on the first request for a missing symbol (Miss File Read), the download of a symbol (Miss File Delete), and a failed symbol lookup (Miss File Write).</p> <p>Use the "Miss File XXX/sec" counters to monitor the operations.</p> <p>It is safe to delete .miss files while the SymProxy is running:</p> <p>C:> del C:\SymStore\Symbols\miss /s</p>

<p>MissFileThreads</p>	<p>By default, SymProxy performs up to 16 concurrent asynchronous file I/O operations for the Miss File feature. Creating the REG_DWORD:" MissFileThreads" value overrides the default limit. Values can be between 1 and 64.</p> <p>Use the "Miss File Queue Depth" counter to monitor the load.</p>
<p>FailureTimeout</p> <p>FailureCount</p> <p>FailurePeriod</p> <p>FailureBlackout</p>	<p>The Blackout feature is used to temporarily disable upstream symbol stores that are unresponsive. The Blackout feature uses 4 REG_DWORD values to define the behaviour. By default, the feature is disabled.</p> <p>For each upstream symbol store defined in a Symbol Path, failures are individually recorded. If a request takes longer than FailureTimeout (msec), the failure count is incremented.</p> <p>The Symbol Path is marked as dead after FailureCount failures in FailurePeriod seconds. At this time, all requests are ignored until FailureBlackout seconds have elapsed. The first caller after the timeout tests the upstream symbol store. On success, the timeout is removed and requests are allowed. On failure, the time is set to Now+FailureBlackout seconds. After that time, the upstream symbol store is tested again.</p>

Accessing Outside Network Resources

When SymSrv is used in conjunction with SymProxy, it runs as a service and uses the WinHTTP API to access symbols over an HTTP connection. This differs from its usual behavior of using WinInet for this purpose.

Consequently, you may need to set up HTTP proxy settings so that this service can access outside network resources. Use one of the following methods to configure these settings:

- In Windows Vista, Windows Server 2008, and later versions of Windows, use the Netsh tool (netsh.exe). For instructions, type the following in a Command Prompt window: `netsh winhttp -?`

The default behavior of SymProxy is to use whatever HTTP proxy is designated by either ProxyCfg or Netsh. If no HTTP proxy is configured, SymProxy uses a dummy proxy to allow access to secure HTTP sites within your intranet. As a side effect, this technique prevents SymProxy from working with direct connections to the external Internet. If you wish to permit SymProxy to operate with a direct connection to the Internet, create a REG_DWORD value named **NoInternetProxy** in the **Symbol Server Proxy** key of your registry. Set the value of **NoInternetProxy** to 1 and verify that there is no HTTP proxy indicated by ProxyCfg.

Choosing Network Security Credentials

5/26/2017 • 3 min to read • [Edit Online](#)

The symbol proxy server must run from a security context with the appropriate privileges for access to the symbol stores that you plan to use. If you obtain symbols from an external Web store such as <https://msdl.microsoft.com/download/symbols>, the symbol proxy server must access the Web from outside of any firewalls. If you obtain files from other computers on your network, the symbol proxy server must have appropriate privileges to read files from those locations. Two possible choices are to set the symbol proxy server to authenticate as the **Network Service** account or to create a user account that is managed within Active Directory Domain Services along with other user accounts.

Note It is a good practice to limit privileges of this account to only those necessary to read files and copy them to c:\symstore. This restriction prevents clients that access your HTTP store from corrupting the system.

Note Make sure the options presented here make sense in your environment. Different organizations have different security needs and requirements. Modify the process outlined here to support the security requirements of your organization.

Authenticate as a Network Service

The **Network Service** account is built in to Windows, so there is no extra step of creating a new account. For this example, we name the computer where the symbol proxy server is being configured *SymMachineName* on a domain named *corp*.

External symbol stores or Internet proxies must be configured to allow this computer's **Network Service** account (Machine Account) to authenticate successfully. There are two ways to achieve this:

- Allow access to the **Authenticated Users** group on the external store or Internet proxy.
- Allow access to the Machine Account *corp\SymMachineName\$*. This option is more secure because it limits access to just the symbol proxy server's "Network Service" account.

Authenticate as a Domain User

For this example, we will presume the user account is named *SymProxyUser* on a domain called *corp*.

To add the user account to the IIS_USRS group

1. From **Administrative Tools** open **Computer Management**.
2. Expand **Local Users and Groups**.
3. Click **Groups**.
4. Double-click **IIS_USRS** in the center pane and select **Properties**.
5. Under the **Members** section, click **Add**.
6. Type *corp\SymProxyUser* in the pane labeled **Enter the object name to select**.
7. To exit the **Select Users, Computer, or Groups** dialog box, click **OK**.
8. To exit **IIS_USRS Properties**, click **OK**.
9. Close the **Computer Management** console.

Set up IIS to use the account

1. From **Administrative Tools** open **Internet Information Services (IIS) Manager**.
2. Expand **Web Sites**.
3. Right click **Default Web Site** and choose **Properties**.
4. Click the **Directory Security** tab.
5. In the **Authentication and access control** section, click **Edit...**.
6. Make sure that *Enable anonymous access* is checked.
7. Enter the credentials of the account that has permissions to access the remote symbol server store(s) ("corp\SymProxyUser") , then click **OK**.
8. Re-enter the password when asked and click **OK**.
9. To exit **Default Web Site Properties**, click **OK**.
10. You may be presented with the *Inheritance Overrides* dialog. If so, select which virtual directories you want to have this apply to.

Authenticate as a Domain User Using the IIS_WPG group

For this example, the user account is named *SymProxyUser* on a domain named *corp*. To authenticate this user account, it must be added to the **IIS_WPG** group.

To add the user account to the IIS_WPG group

1. From **Administrative Tools** open **Computer Management**.
2. Expand **Local Users and Groups**.
3. Click **Groups**.
4. Double-click **IIS_WPG** in the right pane.
5. Click **Add**.
6. Type *corp\SymProxyUser* in the pane labeled **Enter the object name to select**.
7. To exit the **Select Users, Computer, or Groups** dialog box, click **OK**.
8. To exit **IIS_WPG Properties**, click **OK**.
9. Close the **Computer Management** console.

Configuring IIS for SymProxy

5/26/2017 • 1 min to read • [Edit Online](#)

Internet Information Services (IIS) must be configured to use SymProxy as an Internet Server Application Programming Interface (ISAPI) filter. Furthermore, permissions must be set so that IIS can obtain symbols.

To configure the application pool

1. From **Administrative Tools** open **Internet Information Services (IIS) Manager**.
2. Expand the entry with the computer name on the left and locate **Application Pools**.
3. Right-click **Application Pools** and choose **Add Application Pool**.
4. For the **Name** type *SymProxy App Pool*.
5. Under **.Net Framework version** select *None*
6. Click **OK** to create the application pool.
7. Next, right click the entry for the new application pool and select **Advanced Settings....**
8. Under **Process Model**, you will see **Identity**. Click the button at the right labeled "....".
 - a. If you are authenticating as a network service, select **Predefined** for the **Application Pool Identity** and then select **Network Service**.
 - b. If you are authenticating as a domain user, select **Custom account** and then click the **Set** button. Type the credentials of the account that has permissions to access the remote symbol server store (for example, *corp\SymProxyUser*), and click **OK**.
9. Click **OK** to exit the **Application Pool Identity** dialog.
10. Click **OK** to exit the **Advanced Settings** dialog.

To set up the Virtual Directory

1. Expand **Web Sites**.
2. Select **Default Web Site**.
3. Right-click the **Symbols** virtual directory and choose **Properties**.
4. In the **Virtual Directory** tab, click **Create**.
5. From the **Application Pool** drop-down menu, choose **SymProxy App Pool**.
6. To exit **Symbols Properties**, click **OK**.

Configure the ISAPI Filter

1. Right-click the **Default Web Site** and select **Properties**.
2. Double-click **ISAPI Filters**.
3. Right click the center pane under the column **Name** and select Click **Add**.
4. For **Filter Name** type **SymProxy** or some other meaningful name.
5. For **Executable** type *c:\windows\system32\inetsrv\symproxy.dll*.

6. To exit the **Filter Properties** dialog, click **OK**.
7. To exit **Default Web Site Properties**, click **OK**.

Setting Up Exclusion Lists

5/26/2017 • 1 min to read • [Edit Online](#)

In some environments, you may find yourself debugging systems that have a large quantity of modules loaded for which you cannot obtain symbols. This is often the case if you have code that is called by a third-party vendor. This can result in a lot of failed attempts to find symbols, which is time-consuming and clogs up network resources. To alleviate this situation, you can use an *exclusion list* to specify symbols that should be excluded from the search. This feature exists in the client debugger, but you can also configure the SymProxy filter to use its own the exclusion list and prevent such network activity where it is most likely to take up resources.

The exclusion list is made up of the names of the files for which you want to prevent processing. The file names can contain wildcards. For example:

```
dbghelp.pdb
symsrv.*
mso*
```

The list can be implemented in two ways. The first is in an .ini file, %WINDIR%\system32\inetsrv\Symsrv.ini. A section called "exclusions" should contain the list:

```
[exclusions]
dbghelp.pdb
symsrv.*
mso*
```

Alternatively, you can store the exclusions in the registry. Create a key named

```
HKLM\ Software\Microsoft\Symbol Server\Exclusions
```

Store the file name list as string values (REG_SZ) within this key. The name of the string value acts as the file name to exclude. The contents of the string value can be used as a comment describing why the file is being excluded.

SymProxy reads from the exclusion list every half-hour so that you do not need to restart the Web service to see changes take effect. Add files to the list in the registry or .ini file and wait a short period for the exclusions to be used.

Note SymProxy does not support the use of both Symsrv.ini and the registry. If the .ini file exists, it is used. Otherwise, the registry is checked.

Dealing with Unavailable Symbol Stores

5/26/2017 • 1 min to read • [Edit Online](#)

If one of the symbol stores that SymSrv is configured to obtain files from is down or otherwise unavailable, the result can be long waits from the client for every file request. When SymSrv is called from SymProxy, you can avoid most of these waits by setting up SymSrv to stop trying to access the store in question. When this feature is engaged, SymSrv stops trying to use the store for a set period of time after it experiences a specified number of timeouts from the same store during a set interval. The values of these variables can be controlled either by an .ini file or from the registry.

To control symbol store access using a .ini file

1. In %WINDIR%\system32\inetsrv\Symsrv.ini, create a section called **timeouts**.
2. Add the values **trigger**, **count**, and **blackout** to this section.

Trigger indicates the amount of time in minutes to watch for timeouts. **Count** indicates the number of timeouts to look for during the **trigger** period. **Blackout** indicates the length of time in minutes to disable the store after the threshhold is reached.

For example, we recommend the following settings:

```
[timeouts]
trigger=10
count=5
blackout=15
```

In this example, the store access is turned off if five timeouts are experienced in a 10-minute period. At the completion of a 15-minute blackout, the store is reactivated.

To control symbol store access using the registry

1. Create a key named

```
HKLM\ Software\Microsoft\Symbol Server\Timeouts
```

2. Add three REG_DWORD values **trigger**, **count**, and **blackout** to this key. Set these values as you would in the .ini file.

Whether using the registry or an .ini file, if any of the trigger, count, or blackout values are set to 0 or if any of the keys or values do not exist, this functionality is disabled.

This feature of SymSrv is currently available only when running as a service. This means that the only practical application of this feature is when it is called from SymProxy.

Checking and Updating Status

5/26/2017 • 1 min to read • [Edit Online](#)

It is possible to see where SymProxy is configured to acquire symbols by using a web browser. Add `\status` to the server URL get the status information. For example, if the symbols Web site is <http://symbols.contoso.com>, go to <http://symbols.contoso.com/status>. You can also use this to cause symproxy to re-read its configuration information after making a change to the registry. This changes the paths without having to restart the IIS service.

[Send comments about this topic to Microsoft](#)

Handling File Pointers

5/26/2017 • 1 min to read • [Edit Online](#)

A UNC symbol store supports placing the actual files to be served in a separate location, with the client code finding the location of the files through file pointers. These pointers are generated in the symbol store using SymStore with the **/p** option. This handling is supported with other HTTP-based symbol stores only if the file pointers point to a UNC location that is directly accessible by the client. When SymProxy is loaded into the Web server, file-pointer handling is automatically enhanced. The client no longer needs to be able to directly access the target files because SymProxy serves them through the HTTP interface.

Because this feature is automatically applied, an option exists to turn it off in case you must use the proxy for serving some files and regular file pointer implementation for others. To do this, create a REG_DWORD called "NoFilePointerHandler" in **HKLM\Software\Microsoft\Symbol Server**. Set this value to 1 (or anything other than 0) to turn off the internal file pointer handler in SymProxy.

[Send comments about this topic to Microsoft](#)

Caching Acquired Symbol Files

5/26/2017 • 1 min to read • [Edit Online](#)

Typically, SymProxy caches the files that it acquires in the directory designated within Internet Information Services (IIS) as the virtual root for the associated Web site. Then IIS makes the file available to the client debugger. Because the debugger cannot open a file directly from HTTP, it copies the file to a local cache, specified by the symbol path:

```
srv*c:\localcache*http://server/symbols
```

In this example, the client debugger copies the file to c:\localcache. In a situation such as this, the file is copied twice - once by SymProxy to the virtual root of the Web site, and again by the debugger to its local cache.

It is possible to avoid the second copy operation and speed up processing. To do this, you must first share the virtual root of the Web site as a UNC path that can be accessed by the debuggers. For sake of example, this path is named \\server\symbols. You must then remove the IIS configuration for MIME types:

To remove the IIS configuration for MIME types

1. From **Administrative Tools** open **Internet Information Services (IIS) Manager**.
2. Expand **Web Sites**.
3. Right-click **Default Web Site**.
4. Right-click the **Symbols** virtual directory and select **Properties**.
5. Click the **HTTP Headers** tab.
6. Click **MIME Types**.
7. Select all types in the list box labeled **Registered MIME Types**.
8. Click **Remove**.
9. To exit the **MIME Types** dialog, click **OK**.
10. To exit **Symbols Properties**, click **OK**.

This causes IIS to return **file not found** to the debugging client for all transactions on the Web site. However, it does not prevent SymProxy from populating the virtual root with the file.

After you remove the IIS configuration for MIME types, configure the debugger clients to look for symbols first in the HTTP store and in the share that maps to the virtual root of the store with the command:

```
srv**http://server/symbols;srv*\server\symbols
```

In the preceding example, the first element of the symbol path (srv**http://server/symbols) says to get files from the HTTP store and copy them to the default symbol store as a local cache. The specified cache is of no importance because no file is ever received from the HTTP store. After this failure, it attempts to obtain the file from the actual location of the virtual root of the store (srv*\server\symbols). This attempt succeeds because the file is copied to that location as a side effect of the previous path processing.

SymProxy Automated Installation

5/31/2017 • 2 min to read • [Edit Online](#)

These steps along with the Install.cmd script below can help automate the installation of SymProxy to a default IIS installation. You will likely need to adapt these steps to the specific needs of your environment.

1. Create D:\SymStore\Symbols folder.
 - Grant Read to Everyone
 - Grant Read\Write to the SymProxy App Pool user account (Domain\User)
2. Share D:\SymStore\Symbols as Symbols.
 - Grant Read to Everyone (or be more specific)
3. (Optionally) Create an empty file called index2.txt in D:\SymStore\Symbols.
4. (Optionally) Create an empty file called %WINDIR%\system32\inetsrv\symsrv.yes. This accepts the EULA for the Microsoft Public Symbol Store.
5. Determine the parameters for Install.cmd and run it.
6. Configure the clients symbol path using the server name that you created.

```
SRV*\MachineName\Symbols*http://MachineName/Symbols
```

The Install.cmd script requires 3 parameters:

- Virtual Directory path (e.g. D:\SymStore\Symbols)
- Username (for the Application Pool)
- Password (for the Application Pool)

To clear the MIME Type inheritance, an XML file is needed to drive the associated AppCmd.exe command. Place the staticContentClear.xml file shown below in the same folder as the Install.cmd script to achieve this result.

Example Install.Cmd parameter usage:

```
Install.cmd D:\SymStore\Symbols CONTOSO\SymProxyService Pa$$word
```

Install.cmd

```

@echo off

SET VirDirectory=%1
SET UserName=%2
SET Password=%3

::

:: SymProxy dll installation.
::

[name='SymProxy',path='%windir%\system32\inetsrv\SymProxy.dll',enabled='True']

rem Clear the MIME Types on the 'Default Web Site'
%windir%\system32\inetsrv\appcmd.exe set config -in "Default Web Site" < staticContentClear.xml

rem Add * to the MIME Types of the 'Default Web Site'
%windir%\system32\inetsrv\appcmd.exe set config "Default Web Site" -section:staticContent /+
[fileExtension='.*',mimeType='application/octet-stream']"

```

staticContentClear.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<appcmd>
  <CONFIG CONFIG.SECTION="system.webServer/staticContent" path="MACHINE/WEBROOT/APPHOST">
    <system.webServer-staticContent>
      <clear />
    </system.webServer-staticContent>
  </CONFIG>
```

Testing the SymProxy Installation

The system should now be ready to acquire and serve files. To test it, start by restarting the IISAdmin service by running `iisreset.exe`. This will reload the ISAPI filter with the current IIS and SymProxy configuration.

Configure a debugger to use this symbol path:

```
srv*\MachineName\Symbols*http://MachineName/Symbols
```

If `MissTimeout` is enabled (it is set to 300 seconds by default), running the `.reload /f` command twice should result in much faster execution the second time.

To view the location of the PDBs being referenced, use the `lm` (list modules) command. The path to the PDBs should all begin with `\MachineName\Symbols`.

If directory browsing is enabled on the web site, browse to <http://MachineName/Symbols> to see the files that are cached.

Open the Performance Monitor and view the Symbol Proxy counters.

Open the Event Viewer and view the `Microsoft\Windows\SymProxy` events.

Other Symbol Stores

5/26/2017 • 1 min to read • [Edit Online](#)

It is possible to write your own symbol store creation program, rather than using SymStore.

Since SymStore transactions are all logged in CSV-format text files, you can leverage any existing SymStore log files for use in your own database program.

If you plan to use the SymSrv program provided with Debugging Tools for Windows package, it is recommended that you use SymStore as well. Updates to these two programs will always be released together, and therefore their versions will always match.

[Send comments about this topic to Microsoft](#)

Other Symbol Servers

5/26/2017 • 2 min to read • [Edit Online](#)

If you wish to use a different method for your symbol search, you can provide your own symbol server DLL rather than using SymSrv.

Setting the Symbol Path

When implementing a symbol server other than SymSrv, the debugger's symbol path is set in the same way as with SymSrv. See [SymSrv](#) for an explanation of the symbol path syntax. The only change you need to make is to replace the string **symsrv.dll** with the name of your own symbol server DLL.

If you wish, you are free to use a different syntax within the parameters to indicate the use of different technologies such as UNC paths, SQL database identifiers, or Internet specifications.

Implementing Your Own Symbol Server

The central portion of the server is the code that communicates with DbgHelp to find the symbols. Every time DbgHelp requires symbols for a newly loaded module, it calls the symbol server to locate the appropriate symbol files. The symbol server locates each file according to unique parameters such as the time stamp or image size. The server returns a validated path to the requested file. To implement this, the server must export the **SymbolServer** function.

The server should also support the **SymbolServerSetOptions** and **SymbolServerGetOptions** functions. And DbgHelp will call the **SymbolServerClose** function, if it is exported by the server. See [Symbol Server API](#) for information about where these routines are documented.

You must not change the actual symbol file name returned by your symbol server. DbgHelp stores the name of a symbol file in multiple locations. Therefore, the server must return a file of the same name as that specified when the symbol was requested. This restriction is needed to assure that the symbol names displayed during symbol loading are the ones that the programmer will recognize.

Restrictions on Multiple Symbol Servers

DbgHelp supports the use of only one symbol server at a time. Your symbol path can contain multiple instances of the same symbol server DLL, but not two different symbol server DLLs. This is not much of a restriction, since you are still free to include multiple instances of a symbol server in your symbol path, each pointing to a different symbol store. But if you want to switch between two different symbol server DLLs, you will have to change the symbol path each time.

Installing Your Symbol Server

The details of your symbol server installation will depend on your situation. You might wish to set up an installation process that copies your symbol server DLL and sets the `_NT_SYMBOL_PATH` environment variable automatically.

Depending on the technology used in your server, you may also need to install or access the symbol data itself.

[Send comments about this topic to Microsoft](#)

Deferred Symbol Loading

5/26/2017 • 1 min to read • [Edit Online](#)

By default, symbol information is not actually loaded when the target modules are loaded. Instead, symbols are loaded by the debugger as they are needed. This is called *deferred symbol loading* or *lazy symbol loading*. When this option is enabled, the debugger loads symbols whenever it encounters an unrecognized symbol.

When the symbol path is changed, for example by using the **.sympath (Set Symbol Path)** command, all loaded modules with export symbols are lazily reloaded. Symbols of modules with full PDB symbols will be lazily reloaded if the new path no longer includes the original path that was used to load the PDB symbols. If the new path still includes the original path to the PDB symbol file, those symbols will not be lazily reloaded.

When deferred symbol loading is disabled, process startup can be much slower, because all symbols are read whenever a module is loaded.

In WinDbg, the deferred symbol loading behavior can be modified for symbols that have no module prefix by using the **Resolve Unqualified Symbols** option on the **Debug** menu.

You can override deferred symbol loading by using the **!ld (Load Symbols)** command or the **.reload (Reload Module)** command with the **/f** option. These force the specified symbols to be loaded immediately, although the loading of other symbols is deferred.

By default, deferred symbol loading is enabled. In CDB and KD, the **-s command-line option** will turn this option off. It can also be turned off in CDB by using the *LazyLoad* variable in the *tools.ini* file. Once the debugger is running, this option can be turned on or off by using **.sympopt+0x4** or **.sympopt-0x4**, respectively.

Avoiding debugger searches for unneeded symbols

5/26/2017 • 4 min to read • [Edit Online](#)

Last updated:

- May 27, 2007

You arrive at an interesting breakpoint while debugging your driver, only to have the debugger pause for a very long time while it attempts to load symbols for drivers that you don't own and that don't even matter for the debugging task at hand. What's going on?

By default, symbols are loaded by the debugger as they are needed. (This is called deferred symbol loading or lazy symbol loading.) The debugger looks for symbols whenever it executes a command that calls for the display of symbols. This can happen at a breakpoint if you have set a watch variable that is not valid in the current context, such as a function parameter or local variable that doesn't exist in the current stack frame, because they become invalid when the context changes. It can also happen if you simply mistype a symbol name or execute an invalid debugger command—the debugger starts looking for a matching symbol.

Why does this sometimes take so long? That depends on whether the symbol name is qualified or unqualified. A qualified symbol name is preceded with the name of the module that contains the symbol—for example, `myModule!myVar`. An unqualified symbol name does not specify a module name—for example, `myOtherVar`.

In the case of the qualified name, the debugger looks for the symbol in the specified module and, if the module is not already loaded, loads the module (assuming the module exists and contains the symbol). This happens fairly quickly.

In the case of an unqualified name, the debugger doesn't "know" which module contains the symbol, so it must look in all of them. The debugger first checks all loaded modules for the symbol and then, if it cannot match the symbol in any loaded module, the debugger continues its search by loading all unloaded modules, starting with the downstream store and ending with the symbol server, if you're using one. Obviously, this can take a lot of time.

How to prevent automatic loading for unqualified symbols

The **SYMOPT_NO_UNQUALIFIED_LOADS** option disables or enables the debugger's automatic loading of modules when it searches for an unqualified symbol. When **SYMOPT_NO_UNQUALIFIED_LOADS** is set and the debugger attempts to match an unqualified symbol, it searches only modules that have already been loaded, and stops searching when it cannot match the symbol, instead of loading unloaded modules to continue its search. This option does not affect searching for qualified names.

SYMOPT_NO_UNQUALIFIED_LOADS is off by default. To activate this option, use the **-snul** command-line option or, while the debugger is running, use **.symopt+0x100** or **.symopt-0x100** to turn the option on or off, respectively.

To see the effect of **SYMOPT_NO_UNQUALIFIED_LOADS**, try this experiment:

1. Activate noisy symbol loading (**SYMOPT_DEBUG**) by using the **-n** command-line option or, if the debugger is already running, use **.symopt+0x80000000** or the **!sym noisy** debugger extension command.
SYMOPT_DEBUG instructs the debugger to display information about its search for symbols, such as the name of each module as it is loaded or an error message if the debugger cannot find a file.
2. Instruct the debugger to evaluate a nonexistent symbol (for example, type **?asdasdasd**). The debugger should report numerous errors while it searches for the nonexistent symbol.
3. Activate **SYMOPT_NO_UNQUALIFIED_LOADS** by using **.symopt+0x100**.

4. Repeat step 2. The debugger should search only loaded modules for the nonexistent symbol, and it should finish the task much faster.
5. To disable **SYMOPT_DEBUG**, use **.symopt-0x80000000** or the **!sym quiet** debugger extension command.

A number of options are available to control how the debugger loads and uses symbols. For a complete list of symbol options and how to use them, see "Setting Symbol Options" in the online documentation provided with Debugging Tools for Windows. The latest release of the Debugging Tools for Windows package is available as a free download from the web, or you can install the package from the Windows DDK, Platform SDK, or Customer Support Diagnostics CD.

What should you do?

- To speed up symbol searching, use qualified names in breakpoints and debugger commands whenever possible. If you want to see a symbol from a known module, qualify it with the module name; if you don't know where the symbol is, use an unqualified name. For local variables and function arguments, use **\$** as the module name (for example, **\$/MyVar**).
- To diagnose the causes of slow symbol loading, activate noisy symbol loading (**SYMOPT_DEBUG**) by using the **-n** command-line option or, if the debugger is already running, by using **.symopt+0x80000000** or the **!sym noisy** debugger extension command.
- To prevent the debugger from searching for symbols in unloaded modules, activate **SYMOPT_NO_UNQUALIFIED_LOADS** by using the **-snul** command-line option or, if the debugger is already running, by using **.symopt+0x100**.
- To explicitly load the modules you need for your debugging session, use debugger commands such as **.reload** or **!ld**.

SymStore

5/26/2017 • 1 min to read • [Edit Online](#)

SymStore (symstore.exe) is a tool for creating symbol stores. It is included in the Debugging Tools for Windows package.

SymStore stores symbols in a format that enables the debugger to look up the symbols based on the time stamp and size of the image (for a .dbg or executable file), or signature and age (for a .pdb file). The advantage of the symbol store over the traditional symbol storage format is that all symbols can be stored or referenced on the same server and retrieved by the debugger without any prior knowledge of which product contains the corresponding symbol.

Note that multiple versions of .pdb symbol files (for example, public and private versions) cannot be stored on the same server, because they each contain the same signature and age.

SymStore Transactions

5/26/2017 • 4 min to read • [Edit Online](#)

Every call to SymStore is recorded as a transaction. There are two types of transactions: add and delete.

When the symbol store is created, a directory, called "000admin", is created under the root of the server. The 000admin directory contains one file for each transaction, as well as the log files server.txt and history.txt. The server.txt file contains a list of all transactions that are currently on the server. The history.txt file contains a chronological history of all transactions.

Each time SymStore stores or removes symbol files, a new transaction number is created. Then, a file, whose name is this transaction number, is created in 000admin. This file contains a list of all the files or pointers that have been added to the symbol store during this transaction. If a transaction is deleted, SymStore will read through its transaction file to determine which files and pointers it should delete.

The **add** and **del** options specify whether an add or delete transaction is to be performed. Including the **/p** option with an add operation specifies that a pointer is to be added; omitting the **/p** option specifies that the actual symbol file is to be added.

It is also possible to create the symbol store in two separate stages. In the first stage, you use SymStore with the **/x** option to create an index file. In the second stage, you use SymStore with the **/y** option to create the actual store of files or pointers from the information in the index file.

This can be a useful technique for a variety of reasons. For instance, this allows the symbol store to be easily recreated if the store is somehow lost, as long as the index file still exists. Or perhaps the computer containing the symbol files has a slow network connection to the computer on which the symbol store will be created. In this case, you can create the index file on the same machine as the symbol files, transfer the index file to the second machine, and then create the store on the second machine.

For a full listing of all SymStore parameters, see [SymStore Command-Line Options](#).

Note SymStore does not support simultaneous transactions from multiple users. It is recommended that one user be designated "administrator" of the symbol store and be responsible for all **add** and **del** transactions.

Transaction Examples

Here are two examples of SymStore adding symbol pointers for build 2195 of Windows 2000 to \\MyDir\\symsrv:

```
symstore add /r /p /f \\BuildServer\BuildShare\2195free\symbols\*.* /s \\MyDir\symsrv /t "Windows 2000" /v  
"Build 2195 x86 free" /c "Sample add"  
symstore add /r /p /f \\BuildServer\BuildShare\2195free\symbols\*.* /s \\MyDir\symsrv /t "Windows 2000" /v  
"Build 2195 x86 checked" /c "Sample add"
```

In the following example, SymStore adds the actual symbol files for an application project in \\largeapp\\appserver\\bins to \\MyDir\\symsrv:

```
symstore add /r /f \\largeapp\appserver\bins\*.* /s \\MyDir\symsrv /t "Large Application" /v "Build 432" /c  
"Sample add"
```

Here is an example of how an index file is used. First, SymStore creates an index file based on the collection of symbol files in \\largeapp\\appserver\\bins\\. In this case, the index file is placed on a third computer, \\hubserver\\hubshare. You use the **/g** option to specify that the file prefix "\\largeapp\\appserver" might change in the future:

```
symstore add /r /p /g \\largeapp\appserver /f \\largeapp\appserver\bins\*.* /x  
\\hubserver\hubshare\myindex.txt
```

Now suppose you move all the symbol files off of the machine \\largeapp\appserver and put them on \\myarchive\appserver. You can then create the symbol store itself from the index file \\hubserver\hubshare\myindex.txt as follows:

```
symstore add /y \\hubserver\hubshare\myindex.txt /g \\myarchive\appserver /s \\MyDir\symsrv /p /t "Large  
Application" /v "Build 432" /c "Sample Add from Index"
```

Finally, here is an example of SymStore deleting a file added by a previous transaction. See "The server.txt and history.txt Files" section below for an explanation of how to determine the transaction ID (in this case, 0000000096).

```
symstore del /i 0000000096 /s \\MyDir\symsrv
```

The server.txt and history.txt Files

When a transaction is added, several items of information are added to server.txt and history.txt for future lookup capability. The following is an example of a line in server.txt and history.txt for an add transaction:

```
0000000096,add,ptr,10/09/99,00:08:32,Windows Vista SP 1,x86 fre 1.156c-RTM-2,Added from \\mybuilds\symbols,
```

This is a comma-separated line. The fields are explained as follows:

FIELD	DESCRIPTION
0000000096	Transaction ID number, as created by SymStore.
add	Type of transaction. This field can be either add or del .
ptr	Whether files or pointers were added. This field can be either file or ptr .
10/09/99	Date when transaction occurred.
00:08:32	Time when transaction started.
Windows Vista SP 1	Product.
x86 fre	Version (optional).
Added from	Comment (optional)
Unused	(Reserved for later use.)

Here are some sample lines from the transaction file 0000000096. Each line records the directory and the location of the file or pointer that was added to the directory.

```
canon800.dbg\35d9fd51b000,\\mybuilds\symbols\sp4\dll\canon800.dbg
canon1bp.dbg\35d9fd521c000,\\mybuilds\symbols\sp4\dll\canon1bp.dbg
certadm.dbg\352bf2f48000,\\mybuilds\symbols\sp4\dll\certadm.dbg
certcli.dbg\352bf2f1b000,\\mybuilds\symbols\sp4\dll\certcli.dbg
certcrpt.dbg\352bf04911000,\\mybuilds\symbols\sp4\dll\certcrpt.dbg
certenc.dbg\352bf2f7f000,\\mybuilds\symbols\sp4\dll\certenc.dbg
```

If you use a **del** transaction to undo the original **add** transactions, these lines will be removed from server.txt, and the following line will be added to history.txt:

```
0000000105,del,0000000096
```

The fields for the delete transaction are described as follows.

FIELD	DESCRIPTION
0000000105	Transaction ID number, as created by SymStore.
del	Type of transaction. This field can be either add or del .
0000000096	Transaction that was deleted.

File System References and Symbol Files

5/26/2017 • 1 min to read • [Edit Online](#)

Files on disk can have both long file names and automatically generated abbreviated MS-DOS compatible 8.3 short file names. After adding a symbol file to a symbol store, it is possible that the symbols in that symbol file may not be accessible during debug if the symbol file contains any abbreviated MS-DOS 8.3 file names.

When the tools create a symbol file, the version of the file name that is recorded in the symbol file debug record depends on the tools and how they are run. If a symbol file has an abbreviated MS-DOS 8.3 file name instead of the actual file name embedded in the record, symbol loading at debug time may experience problems because the abbreviated file names vary from system to system. If this problem occurs, the contents of these symbol files may not be accessible during debug. Whenever possible, the user should refrain from using abbreviated file path names when creating symbol files. Some ways to use abbreviated file names inadvertently are to use the abbreviated file path name for a source file, an *include* directory, or an included library file.

For further information, see [Matching Symbol Names](#).

[Send comments about this topic to Microsoft](#)

SymStore Compressed Files

5/26/2017 • 1 min to read • [Edit Online](#)

SymStore can be used with compressed files in two different ways:

1. Use SymStore with the **/p** option to store pointers to the symbol files. After SymStore finishes, compress the files that the pointers refer to.
2. Use SymStore with the **/x** option to create an index file. After SymStore finishes, compress the files listed in the index file. Then, use SymStore with the **/y** option (and, if you wish, the **/p** option) to store the files or pointers to the files in the symbol store. (SymStore will not need to uncompress the files to perform this operation.)

Your symbol server will be responsible for uncompressing the files at the proper time.

If you are using SymSrv as your symbol server, any compression should be done using the compress.exe tool which is available [here](#). Compressed files should have an underscore as the last character in their file extensions (for example, module1.pd_ or module2.db_). For details, see [SymSrv](#).

[Send comments about this topic to Microsoft](#)

Symbol Storage Format

5/26/2017 • 2 min to read • [Edit Online](#)

SymStore uses the file system itself as a database. It creates a large tree of directories, with directory names based on such things as the symbol file time stamps, signatures, age, and other data.

For example, after several different acpi.dbgs have been added to the server, the directories could look like this:

```
Directory of \\mybuilds\symsrv\acpi.dbg
10/06/1999  05:46p      <DIR>      .
10/06/1999  05:46p      <DIR>      ..
10/04/1999  01:54p      <DIR>      37cdb03962040
10/04/1999  01:49p      <DIR>      37cdb04027740
10/04/1999  12:56p      <DIR>      37e3eb1c62060
10/04/1999  12:51p      <DIR>      37e3ebcc27760
10/04/1999  12:45p      <DIR>      37ed151662060
10/04/1999  12:39p      <DIR>      37ed15dd27760
10/04/1999  11:33a      <DIR>      37f03ce962020
10/04/1999  11:21a      <DIR>      37f03cf7277c0
10/06/1999  05:38p      <DIR>      37fa7f00277e0
10/06/1999  05:46p      <DIR>      37fa7f01620a0
```

In this example, the lookup path for the acpi.dbg symbol file might look like this:

\\mybuilds\symsrv\acpi.dbg\37cdb03962040.

Three files may exist inside the lookup directory:

1. acpi.dbg, if the file was stored
2. file.ptr with a path to the actual symbol file, if a pointer was stored
3. refs.ptr, which contains a list of all the current locations for acpi.dbg with this timestamp and image size that are currently added to the symbol store

Displaying the directory listing of \\mybuilds\symsrv\acpi.dbg\37cdb03962040 gives the following:

```
10/04/1999  01:54p      52 file.ptr
10/04/1999  01:54p      67 refs.ptr
```

The file file.ptr contains the text string "\\mybuilds\symbols\x86\2128.chk\symbols\sys\acpi.dbg". Since there is no file called acpi.dbg in this directory, the debugger will try to find the file at \\mybuilds\symbols\x86\2128.chk\symbols\sys\acpi.dbg.

The contents of refs.ptr are used only by SymStore, not the debugger. This file contains a record of all transactions that have taken place in this directory. A sample line from refs.ptr might be:

```
0000000026,ptr,\\mybuilds\symbols\x86\2128.chk\symbols\sys\acpi.dbg
```

This shows that a pointer to \\mybuilds\symbols\x86\2128.chk\symbols\sys\acpi.dbg was added with transaction "0000000026".

Some symbol files stay constant through various products or builds or a particular product. One example of this is the Windows 2000 file msvcrt.pdb. A directory listing of \\mybuilds\symsrv\msvcrt.pdb shows that only two versions of msvcrt.pdb have been added to the symbols server:

```
Directory of \\mybuilds\symsrv\msvcrt.pdb
10/06/1999  05:37p      <DIR>      .
10/06/1999  05:37p      <DIR>      ..
10/04/1999  11:19a      <DIR>      37a8f40e2
10/06/1999  05:37p      <DIR>      37f2c2272
```

However, a directory listing of \\mybuilds\symsrv\msvcrt.pdb\37a8f40e2 shows that refs.ptr has several pointers in it.

```
Directory of \\mybuilds\symsrv\msvcrt.pdb\37a8f40e2
10/05/1999  02:50p      54      file.ptr
10/05/1999  02:50p      2,039    refs.ptr
```

The contents of \\mybuilds\symsrv\msvcrt.pdb\37a8f40e2\refs.ptr are the following:

```
0000000001,ptr,\\mybuilds\symbols\x86\2137\symbols\dll\msvcrt.pdb
0000000002,ptr,\\mybuilds\symbols\x86\2137.chk\symbols\dll\msvcrt.pdb
0000000003,ptr,\\mybuilds\symbols\x86\2138\symbols\dll\msvcrt.pdb
0000000004,ptr,\\mybuilds\symbols\x86\2138.chk\symbols\dll\msvcrt.pdb
0000000005,ptr,\\mybuilds\symbols\x86\2139\symbols\dll\msvcrt.pdb
0000000006,ptr,\\mybuilds\symbols\x86\2139.chk\symbols\dll\msvcrt.pdb
0000000007,ptr,\\mybuilds\symbols\x86\2140\symbols\dll\msvcrt.pdb
0000000008,ptr,\\mybuilds\symbols\x86\2140.chk\symbols\dll\msvcrt.pdb
0000000009,ptr,\\mybuilds\symbols\x86\2136\symbols\dll\msvcrt.pdb
0000000010,ptr,\\mybuilds\symbols\x86\2136.chk\symbols\dll\msvcrt.pdb
0000000011,ptr,\\mybuilds\symbols\x86\2135\symbols\dll\msvcrt.pdb
0000000012,ptr,\\mybuilds\symbols\x86\2135.chk\symbols\dll\msvcrt.pdb
0000000013,ptr,\\mybuilds\symbols\x86\2134\symbols\dll\msvcrt.pdb
0000000014,ptr,\\mybuilds\symbols\x86\2134.chk\symbols\dll\msvcrt.pdb
0000000015,ptr,\\mybuilds\symbols\x86\2133\symbols\dll\msvcrt.pdb
0000000016,ptr,\\mybuilds\symbols\x86\2133.chk\symbols\dll\msvcrt.pdb
0000000017,ptr,\\mybuilds\symbols\x86\2132\symbols\dll\msvcrt.pdb
0000000018,ptr,\\mybuilds\symbols\x86\2132.chk\symbols\dll\msvcrt.pdb
0000000019,ptr,\\mybuilds\symbols\x86\2131\symbols\dll\msvcrt.pdb
0000000020,ptr,\\mybuilds\symbols\x86\2131.chk\symbols\dll\msvcrt.pdb
0000000021,ptr,\\mybuilds\symbols\x86\2130\symbols\dll\msvcrt.pdb
0000000022,ptr,\\mybuilds\symbols\x86\2130.chk\symbols\dll\msvcrt.pdb
0000000023,ptr,\\mybuilds\symbols\x86\2129\symbols\dll\msvcrt.pdb
0000000024,ptr,\\mybuilds\symbols\x86\2129.chk\symbols\dll\msvcrt.pdb
0000000025,ptr,\\mybuilds\symbols\x86\2128\symbols\dll\msvcrt.pdb
0000000026,ptr,\\mybuilds\symbols\x86\2128.chk\symbols\dll\msvcrt.pdb
0000000027,ptr,\\mybuilds\symbols\x86\2141\symbols\dll\msvcrt.pdb
0000000028,ptr,\\mybuilds\symbols\x86\2141.chk\symbols\dll\msvcrt.pdb
0000000029,ptr,\\mybuilds\symbols\x86\2142\symbols\dll\msvcrt.pdb
0000000030,ptr,\\mybuilds\symbols\x86\2142.chk\symbols\dll\msvcrt.pdb
```

This shows that the same msvcrt.pdb was used for multiple builds of symbols for Windows 2000 stored on \\mybuilds\symsrv.

Here is an example of a directory that contains a mixture of file and pointer additions:

```
Directory of E:\symsrv\dbghelp.dbg\38039ff439000
10/12/1999  01:54p      141,232    dbghelp.dbg
10/13/1999  04:57p      49        file.ptr
10/13/1999  04:57p      306      refs.ptr
```

In this case, refs.ptr has the following contents:

```
0000000043,file,e:\binaries\symbols\retail\dll\dbghelp.dbg
0000000044,file,f:\binaries\symbols\retail\dll\dbghelp.dbg
0000000045,file,g:\binaries\symbols\retail\dll\dbghelp.dbg
0000000046,ptr,\\MyDir\bin\symbols\retail\dll\dbghelp.dbg
0000000047,ptr,\\foo2\bin\symbols\retail\dll\dbghelp.dbg
```

Thus, transactions 43, 44, and 45 added the same file to the server, and transactions 46 and 47 added pointers. If transactions 43, 44, and 45 are deleted, then the file dbghelp.dbg will be deleted from the directory. The directory will then have the following contents:

```
Directory of e:\symsrv\dbghelp.dbg\38039ff439000
10/13/1999  05:01p           49 file.ptr
10/13/1999  05:01p          130 refs.ptr
```

Now file.ptr contains "\\foo2\bin\symbols\retail\dll\dbghelp.dbg", and refs.ptr contains

```
0000000046,ptr,\\MyDir\bin\symbols\retail\dll\dbghelp.dbg
0000000047,ptr,\\foo2\bin\symbols\retail\dll\dbghelp.dbg
```

Whenever the final entry in refs.ptr is a pointer, the file file.ptr will exist and contain the path to the associated file. Whenever the final entry in refs.ptr is a file, no file.ptr will exist in this directory. Therefore, any delete operation that removes the final entry in refs.ptr may result in file.ptr being created, deleted, or changed.

[Symbol Status Abbreviations](#)

[Send comments about this topic to Microsoft](#)

Symbol Syntax and Symbol Matching

5/26/2017 • 3 min to read • [Edit Online](#)

Symbols allow you to directly manipulate tokens that are used by the program being debugged. For example, you can set a breakpoint at the function **main** with the command **bp main**, or display the integer variable **MyInt** with the command **dd MyInt L1**.

In many cases, symbols can be used as parameters in debugger commands. This is supported for most numerical parameters, and is also supported in some text parameters. In addition to general rules for symbol syntax, there are also symbol syntax rules that apply in each of these cases.

General Symbol Syntax Rules

A symbol name consists of one or more characters, but always begins with a letter, underscore (_), question mark (?), or dollar sign (\$).

A symbol name may be qualified by a module name. An exclamation mark (!) separates the module name from the symbol (for instance, **mymodule!main**). If no module name is used, the symbol can still be prefixed with an exclamation mark. Using an exclamation mark with no module name can be especially useful, even for local variables, to indicate to a debugger command that a parameter is a name and not a hexadecimal number. For example, the variable **fade** will be read by the **dt (Display Type)** command as an address, unless it is prefixed by an exclamation mark or the -n option is used. However, to specify that a symbol is local, precede it with a dollar sign (\$) and an exclamation point (!), as in **\$!lime**.

Symbol names are completely case-insensitive. This means that the presence of a **myInt** and a **MyInt** in your program will not be correctly understood by the debuggers; any command that references one of these may access the other one, regardless of how the command is capitalized.

Symbol Syntax in Numerical Expressions

The debugger understands two different kinds of expressions: Microsoft Macro Assembler (MASM) expressions and C++ expressions. As far as symbols are concerned, these two forms of syntax differ as follows:

- In MASM expressions, each symbol is interpreted as an address. Depending on what the symbol refers to, this will be the address of a global variable, local variable, function, segment, module, or any other recognized label.
- In C++ expressions, each symbol is interpreted according to its type. Depending on what the symbol refers to, it may be interpreted as an integer, a data structure, a function pointer, or any other data type. A symbol that does not correspond to a C++ data type (such as an unmodified module name) will result in a syntax error.

For an explanation of when and how to use each type of syntax, see [Evaluating Expressions](#).

If you are using MASM expression syntax, any symbol that could be interpreted as a hexadecimal number or as a register (e.g., **BadFeed**, **ebx**) should always be prefixed by an exclamation point. This makes sure the debugger recognizes it as a symbol.

The **ss (Set Symbol Suffix)** command can be used to set the symbol suffix. This instructs the debugger to automatically append "A" or "W" to any symbol name it cannot find otherwise.

Many Win32 routines exist in both ASCII and Unicode versions. These routines often have an "A" or "W" appended to the end of their names, respectively. Using a symbol suffix will aid the debugger when searching for these symbols.

Suffix matching is not active by default.

Symbol Syntax in Text Expressions

Symbols can be used in the text parameters of some commands -- for example, [bm \(Set Breakpoint\)](#) and [x \(Examine Symbols\)](#).

These text parameters support a variety of wildcards and specifiers. See [String Wildcard Syntax](#) for details. In addition to the standard string wildcards, a text expression used to specify a symbol can be prefixed with a leading underscore. When matching this to a symbol, the debugger will treat this as any quantity of underscores, even zero.

The symbol suffix is not used when matching symbols in text expressions.

[Send comments about this topic to Microsoft](#)

Symbol Options

5/26/2017 • 12 min to read • [Edit Online](#)

A number of options are available to control how symbols are loaded and used. These options can be set in a variety of ways.

The following table lists these symbol options:

FLAG	OPTION NAME	DEFAULT IN DEBUGGER	DEFAULT IN DBH
0x1	SYMOPT_CASE_INSENSITIVE	On	On
0x2	SYMOPT_UNDNAME	On	On
0x4	SYMOPT_DEFERRED_LOADS	On	Off
0x8	SYMOPT_NO_CPP	Off	Off
0x10	SYMOPT_LOAD_LINES	Off in KD and CDB On in WinDbg	On
0x20	SYMOPT_OMAP_FIND_NEAREST	On	Off
0x40	SYMOPT_LOAD_ANYTHING	Off	Off
0x80	SYMOPT_IGNORE_CVREC	Off	Off
0x100	SYMOPT_NO_UNQUALIFIED_LOADS	Off	Off
0x200	SYMOPT_FAIL_CRITICAL_ERRORS	On	Off
0x400	SYMOPT_EXACT_SYMBOLS	Off	On
0x800	SYMOPT_ALLOW_ABSOLUTE_SYMBOLS	Off	On

FLAG	OPTION NAME	DEFAULT IN DEBUGGER	DEFAULT IN DBH
0x1000	SYMOPT_IGNORE_NT_SYMBOLPATH	Off	Off
0x2000	SYMOPT_INCLUDE_32BIT_MODULES	Off	Off
0x4000	SYMOPT_PUBLICS_ONLY	Off	Off
0x8000	SYMOPT_NO_PUBLICS	Off	Off
0x10000	SYMOPT_AUTO_PUBLICS	On	On
0x20000	SYMOPT_NO_IMAGE_SEARCH	On	Off
0x40000	SYMOPT_SECURE	Off	Off
0x80000	SYMOPT_NO_PROMPTS	On in KD and CDB Off in WinDbg	Off
0x80000000	SYMOPT_DEBUG	Off	Off

Changing the Symbol Option Settings

The [.symopt \(Set Symbol Options\)](#) command can be used to change or display the symbol option settings. In addition, a number of command-line parameters and commands are available to change these settings; these are listed in the individual SYMOPT_XXX sections.

You can also control all the settings at once with the [-sflags](#) command-line option. This option can be followed with a decimal number, or with a hexadecimal number prefixed by **0x**. It is recommended that you use hexadecimal, since the symbol flags are aligned properly that way. Be cautious in using this method, since it sets the entire bitfield and will override all the symbol handler defaults. For example, **-sflags 0x401** will not only turn on SYMOPT_EXACT_SYMBOLS and SYMOPT_CASE_INSENSITIVE, but will also turn off all the other options that normally are on by default!

The default value for the total flag bits is 0x30237 in WinDbg, 0xB0227 in CDB and KD, and 0x10C13 in [the DBH tool](#), when these programs are launched without any symbol-related command line options.

SYMOPT_CASE_INSENSITIVE

This symbol option causes all searches for symbol names to be case-insensitive.

This option is on by default in all debuggers. Once the debugger is running, it can be turned on or off by using **.symopt+0x1** or **.symopt-0x1**, respectively.

This option is on by default in DBH. Once DBH is running, it can be turned on or off by using **symopt +1** or **symopt -1**, respectively.

SYMOPT_UNDNAME

This symbol option causes public symbol names to be undecorated when they are displayed, and causes searches for symbol names to ignore symbol decorations. Private symbol names are never decorated, regardless of whether this option is active. For information on symbol name decorations, see [Public and Private Symbols](#).

This option is on by default in all debuggers. Once the debugger is running, it can be turned on or off by using **.symopt+0x2** or **.symopt-0x2**, respectively.

This option is on by default in DBH. It is turned off if the **-d** command-line option is used. Once DBH is running, it can be turned on or off by using **symopt +2** or **symopt -2**, respectively.

SYMOPT_DEFERRED_LOADS

This symbol option is called *deferred symbol loading* or *lazy symbol loading*. When it is active, symbols are not actually loaded when the target modules are loaded. Instead, symbols are loaded by the debugger as they are needed. See [Deferred Symbol Loading](#) for details.

This option is on by default in all debuggers. In CDB and KD, the **-s** command-line option will turn this option off. It can also be turned off in CDB by using the **LazyLoad** variable in the [tools.ini](#) file. Once the debugger is running, this option can be turned on or off by using **.symopt+0x4** or **.symopt-0x4**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using **symopt +4** or **symopt -4**, respectively.

SYMOPT_NO_CPP

This symbol option turns off C++ translation. When this symbol option is set, **::** is replaced by **__** in all symbols.

This option is off by default in all debuggers. It can be activated by using the **-snc** command-line option. Once the debugger is running, it can be turned on or off by using **.symopt+0x8** or **.symopt-0x8**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using **symopt +8** or **symopt -8**, respectively.

SYMOPT_LOAD_LINES

This symbol option allows line number information to be read from source files. This option must be on for source debugging to work correctly.

In KD and CDB, this option is off by default; in WinDbg, this option is on by default. In CDB and KD, the **-lines** command-line option will turn this option on. Once the debugger is running, it can be turned on or off by using **.symopt+0x10** or **.symopt-0x10**, respectively. It can also be toggled on and off by using the [.lines \(Toggle Source Line Support\)](#) command.

This option is on by default in DBH. Once DBH is running, it can be turned on or off by using **symopt +10** or **symopt -10**, respectively.

SYMOPT_OMAP_FIND_NEAREST

When code has been optimized and there is no symbol at the expected location, this option causes the nearest symbol to be used instead.

This option is on by default in all debuggers. Once the debugger is running, it can be turned on or off by using **.symopt+0x20** or **.symopt-0x20**, respectively.

This option is on by default in DBH. Once DBH is running, it can be turned on or off by using **symopt +20** or **symopt -20**, respectively.

SYMOPT_LOAD_ANYTHING

This symbol option reduces the pickiness of the symbol handler when it is attempting to match symbols.

This option is off by default in all debuggers. Once the debugger is running, it can be turned on or off by using

.symopt+0x40 or **.symopt-0x40**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using symopt +40 or symopt -40, respectively.

SYMOPT_IGNORE_CVREC

This symbol option causes the symbol handler to ignore the CV record in the loaded image header when searching for symbols.

This option is off by default in all debuggers. It can be activated by using the -sicv command-line option. Once the debugger is running, it can be turned on or off by using **.symopt+0x80** or **.symopt-0x80**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using symopt +80 or symopt -80, respectively.

SYMOPT_NO_UNQUALIFIED_LOADS

This symbol option disables the symbol handler's automatic loading of modules. When this option is set and the debugger attempts to match a symbol, it will only search modules which have already been loaded.

This option can be used as a defense against mistyping a symbol name. Normally, a mistyped symbol will cause the debugger to pause while it searches all unloaded symbol files. When this option is active, a mistyped symbol will not be found in the loaded modules, and then the search will terminate.

This option is off by default in all debuggers. It can be activated by using the -snul command-line option. Once the debugger is running, it can be turned on or off by using **.symopt+0x100** or **.symopt-0x100**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using symopt +100 or symopt -100, respectively.

SYMOPT_FAIL_CRITICAL_ERRORS

This symbol option causes file access error dialog boxes to be suppressed.

If this option is off, file access errors, such as "drive not ready", encountered during symbol loading, will result in dialog boxes appearing. If this option is on, these boxes are suppressed and all access errors receive a "fail" response.

This option is on by default in all debuggers. It can be deactivated by using the -sdce command-line option. Once the debugger is running, it can be turned on or off by using **.symopt+0x200** or **.symopt-0x200**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using symopt +200 or symopt -200, respectively.

SYMOPT_EXACT_SYMBOLS

This symbol option causes the debugger to perform a strict evaluation of all symbol files.

When this option is on, even the slightest discrepancy between the symbol files and the symbol handler's expectations will cause the symbols to be ignored.

This option is off by default in all debuggers. It can be activated by using the -ses command-line option. Once the debugger is running, it can be turned on or off by using **.symopt+0x400** or **.symopt-0x400**, respectively.

The -failinc command-line option also turns on SYMOPT_EXACT_SYMBOLS. In addition, if you are debugging a user-mode minidump or a kernel-mode minidump, -failinc will prevent the debugger from loading any modules whose images can't be mapped.

This option is on by default in DBH. Once DBH is running, it can be turned on or off by using symopt +400 or symopt -400, respectively.

SYMOPT_ALLOW_ABSOLUTE_SYMBOLS

This symbol option allows DbgHelp to read symbols that are stored at an absolute address in memory. This option is not needed in the vast majority of cases.

This option is off by default in all debuggers. Once the debugger is running, it can be turned on or off by using **.symopt+0x800** or **.symopt-0x800**, respectively.

This option is on by default in DBH. Once DBH is running, it can be turned on or off by using **symopt +800** or **symopt -800**, respectively.

SYMOPT_IGNORE_NT_SYMPATH

This symbol option causes the debugger to ignore the environment variable settings for the symbol path and the executable image path.

This option is off by default in all debuggers. It can be activated by using the **-sins** command-line option. However, it cannot be controlled by **.symopt** once the debugger is running, because the environment variables are only read at startup.

This option is off by default in DBH, and is ignored by DBH in all cases.

SYMOPT_PUBLICS_ONLY

This symbol option causes DbgHelp to ignore private symbol data, and search only the public symbol table for symbol information. This emulates the behavior of DbgHelp before support for these types was added. see [Public and Private Symbols](#).

This option is off by default in all debuggers. Once the debugger is running, it can be turned on or off by using **.symopt+0x4000** or **.symopt-0x4000**, respectively.

This option is off by default in DBH. It is turned on if the **-d** command-line option is used. Once DBH is running, it can be turned on or off by using **symopt +4000** or **symopt -4000**, respectively.

SYMOPT_NO_PUBLICS

This symbol option prevents DbgHelp from searching the public symbol table. This can make symbol enumeration and symbol searches much faster. If you are concerned solely with search speed, the **SYMOPT_AUTO_PUBLICS** option is generally preferable to this one. For information on the public symbol table, see [Public and Private Symbols](#).

This option is off by default in all debuggers. Once the debugger is running, it can be turned on or off by using **.symopt+0x8000** or **.symopt-0x8000**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using **symopt +8000** or **symopt -8000**, respectively.

SYMOPT_AUTO_PUBLICS

This symbol option causes DbgHelp to search the public symbol table in a .pdb file only as a last resort. If any matches are found when searching the private symbol data, the public symbols will not be searched. This improves symbol search speed.

This option is on by default in all debuggers. It can be deactivated by using the **-sup** command-line option. Once the debugger is running, it can be turned on or off by using **.symopt+0x10000** or **.symopt-0x10000**, respectively.

This option is on by default in DBH. It is turned off if the **-d** command-line option is used. Once DBH is running, it can be turned on or off by using **symopt +10000** or **symopt -10000**, respectively.

SYMOPT_NO_IMAGE_SEARCH

This symbol option prevents DbgHelp from searching the disk for a copy of the image when symbols are loaded.

This option is on by default in all debuggers. Once the debugger is running, it can be turned on or off by using

.symopt+0x20000 or **.symopt-0x20000**, respectively.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using symopt +20000 or symopt -20000, respectively.

SYMOPT_SECURE

(Kernel mode only) This symbol option indicates whether [Secure Mode](#) is active.

Secure Mode is off by default in all debuggers. It can be activated by using the **-secure** command-line option. If the debugger is running, is in dormant mode, and has not established any Debugging Servers, Secure Mode can be turned on by using **.symopt+0x40000** or [.secure \(Activate Secure Mode\)](#).

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using symopt +40000 or symopt -40000, respectively.

Secure mode can never be turned off once it has been activated.

SYMOPT_NO_PROMPTS

This symbol option suppresses authentication dialog boxes from the proxy server. This may result in SymSrv being unable to access a symbol store on the internet.

For details, see [Firewalls and Proxy Servers](#).

In KD and CDB, this option is on by default; in WinDbg, this option is off by default. Once the debugger is running, it can be turned on or off by using **.symopt+0x80000** or **.symopt-0x80000**, respectively, followed by the [.reload \(Reload Module\)](#) command. It can also be turned on and off by using the [!sym prompts off](#) and [!sym prompts](#) extension commands, followed by the [.reload \(Reload Module\)](#) command.

This option is off by default in DBH. Once DBH is running, it can be turned on or off by using symopt +80000 or symopt -80000, respectively.

-SYMOPT_DEBUG

This symbol option turns on *noisy symbol loading*. This instructs the debugger to display information about its search for symbols.

The name of each symbol file will be displayed as it is loaded. If the debugger cannot load a symbol file, it will display an error message. Error messages for .pdb files will be displayed in text. Error messages for .dbg files will be in the form of an error code; these codes are explained in the winerror.h file.

If an image file is loaded solely to recover symbolic header information, this will be displayed as well.

This option is off by default in all debuggers. It can be activated by using the **-n** command-line option. Once the debugger is running, it can be turned on or off by using **.symopt+0x80000000** or **.symopt-0x80000000**, respectively. It can also be turned on and off by using the [!sym noisy](#) and [!sym quiet](#) extension commands.

Note This option should not be confused with noisy *source* loading -- that is controlled by the [.srcnoisy \(Noisy Source Loading\)](#) command.

This option is off by default in DBH. It can be activated by using the **-n** command-line option. Once DBH is running, it can be turned on or off by using symopt +80000000 or symopt -80000000, respectively. It can also be turned on and off by using the verbose on and verbose off commands.

Symbol Status Abbreviations

5/26/2017 • 1 min to read • [Edit Online](#)

Symbol file types and their loading status can be determined by using the [!lm \(List Loaded Modules\)](#) command, the [!lmi](#) extension, or WinDbg's [Debug | Modules](#) menu command.

Each of these displays information about loaded modules and their symbols.

The following abbreviations are used in the displays generated by these commands:

ABBREVIATION	MEANING
deferred	The module has been loaded, but the debugger has not attempted to load the symbols. Symbols will be loaded when needed. See Deferred Symbol Loading for details.
#	There is a mismatch between the symbol file and the executable, either in their timestamps or in their checksums.
T	The timestamp is missing, not accessible, or equal to zero.
C	The checksum is missing, not accessible, or equal to zero.
DIA	Symbol files were loaded through Debug Interface Access (DIA).
Export	No actual symbol files were found, so symbol information was extracted from the binary file's export table.
M	There is a mismatch between the symbol file and the executable, either in their timestamps or in their checksums. However, symbol files have been loaded anyway due to the symbol option settings.
PERF	This binary contains performance-optimized code . Standard address arithmetic may not produce correct results.
Stripped	Debug information was stripped from the image file.
PDB	The symbols are in .pdb format.
COFF	The symbols are in common object file format (COFF) symbol format.

Symbol Problems While Debugging

5/26/2017 • 1 min to read • [Edit Online](#)

Invalid or missing symbols are one of the most common causes of debugger problems. When you see some sort of problem, you need to find out if you have a symbol issue.

In some cases, the solution involves acquiring the correct symbol files. In other cases, you simply need to reconfigure the debugger to recognize symbol files you already have. But if you are not able to get the correct symbol files, you will need to work around this problem and debug the target in a more limited manner.

This section includes:

[Verifying Symbols](#)

[Matching Symbol Names](#)

[Reading Symbols from Paged-Out Headers](#)

[Mapping Symbols When the PEB is Paged Out](#)

[Debugging User-Mode Processes Without Symbols](#)

[Debugging Performance-Optimized Code](#)

[Send comments about this topic to Microsoft](#)

Verifying Symbols

5/26/2017 • 10 min to read • [Edit Online](#)

Symbol problems can show up in a variety of ways. Perhaps a stack trace shows incorrect information or fails to identify the names of the functions in the stack. Or perhaps a debugger command failed to understand the name of a module, function, variable, structure, or data type.

If you suspect that the debugger is not loading symbols correctly, there are several steps you can take to investigate this problem.

First, use the **!m (List Loaded Modules)** command to display the list of loaded modules with symbol information. The most useful form of this command is the following:

```
0:000> !ml
```

If you are using WinDbg, the **Debug | Modules** menu command will let you see this information as well.

Pay particular attention to any notes or abbreviations you may see in these displays. For an interpretation of these, see [Symbol Status Abbreviations](#).

If you don't see the proper symbol files, the first thing to do is to check the symbol path:

```
0:000> .sympath
Current Symbol Path is: d:\MyInstallation\i386\symbols\retail
```

If your symbol path is wrong, fix it. If you are using the kernel debugger make sure your local %WINDIR% is not on your symbol path.

Then reload symbols using the **.reload (Reload Module)** command:

```
0:000> .reload ModuleName
```

If your symbol path is correct, you should activate *noisy mode* so you can see which symbol files **!bghelp** is loading. Then reload your module. See [Setting Symbol Options](#) for information about how to activate noisy mode.

Here is an example of a "noisy" reload of the Microsoft Windows symbols:

```
kd> !sym noisy
kd> .reload nt
1: Kernel Version 2081 MP Checked
2: Kernel base = 0x80400000 PsLoadedModuleList = 0x80506fa0
3: DBGHELP: FindExecutableImageEx-> Looking for D:\MyInstallation\i386\ntkrnlmp.exe...mismatched timestamp
4: DBGHELP: No image file available for ntkrnlmp.exe
5: DBGHELP: FindDebugInfoFileEx-> Looking for
6: d:\MyInstallation\i386\symbols\retail\symbols\exe\ntkrnlmp.dbg... no file
7: DBGHELP: FindDebugInfoFileEx-> Looking for
8: d:\MyInstallation\i386\symbols\retail\symbols\exe\ntkrnlmp.pdb... no file
9: DBGHELP: FindDebugInfoFileEx-> Looking for d:\MyInstallation\i386\symbols\retail\exe\ntkrnlmp.dbg... OK
10: DBGHELP: LocatePDB-> Looking for d:\MyInstallation\i386\symbols\retail\exe\ntkrnlmp.pdb... OK
11: *** WARNING: symbols checksum and timestamp is wrong 0x0036a4ea 0x00361a83 for ntkrnlmp.exe
```

The symbol handler first looks for an image that matches the module it is trying to load (lines three and four). The image itself is not always necessary, but if an incorrect one is present, the symbol handler will often fail. These lines

show that the debugger found an image at **D:\MyInstallation\i386\ntkrnlmp.exe**, but the time-date stamp didn't match. Because the time-date stamp didn't match, the search continues. Next, the debugger looks for a .dbg file and a .pdb file that match the loaded image. These are on lines 6 through 10. Line 11 indicates that even though symbols were loaded, the time-date stamp for the image did not match (that is, the symbols were wrong).

If the symbol-search encountered a catastrophic failure, you would see a message of the form:

```
ImgHlpFindDebugInfo(00000000, module.dll, c:\MyDir;c:\SomeDir, 0823345, 0) failed
```

This could be caused by items such as file system failures, network errors, and corrupt .dbg files.

Diagnosing Symbol Loading Errors

When in noisy mode, the debugger may print out error codes when it cannot load a symbol file. The error codes for .dbg files are listed in winerror.h. The .pdb error codes come from another source and the most common errors are printed in plain English text.

Some common error codes for .dbg files from winerror.h are:

0xB
ERROR_BAD_FORMAT

0x3
ERROR_PATH_NOT_FOUND

0x35
ERROR_BAD_NETPATH

It's possible that the symbol file cannot be loaded because of a networking error. If you see ERROR_BAD_FORMAT or ERROR_BAD_NETPATH and you are loading symbols from another machine on the network, try copying the symbol file to your host computer and put its path in your symbol path. Then try to reload the symbols.

Verifying Your Search Path and Symbols

Let "c:\MyDir;c:\SomeDir" represent your symbol path. Where should you look for debug information?

In cases where the binary has been stripped of debug information, such as the free builds of Windows, first look for a .dbg file in the following locations:

```
c:\MyDir\symbols\exe\ntoskrnl.dbg
c:\SomeDir\symbols\exe\ntoskrnl.dbg
c:\MyDir\exe\ntoskrnl.dbg
c:\SomeDir\exe\ntoskrnl.dbg
c:\MyDir\ntoskrnl.dbg
c:\SomeDir\ntoskrnl.dbg
current-working-directory\ntoskrnl.dbg
```

Next, look for a .pdb file in the following locations:

```
c:\MyDir\symbols\exe\ntoskrnl.pdb
c:\MyDir\exe\ntoskrnl.pdb
c:\MyDir\ntoskrnl.pdb
c:\SomeDir\symbols\exe\ntoskrnl.pdb
c:\SomeDir\exe\ntoskrnl.pdb
c:\SomeDir\ntoskrnl.pdb
current-working-directory\ntoskrnl.pdb
```

Note that in the search for the .dbg file, the debugger interleaves searching through the MyDir and SomeDir directories, but in the .pdb search it does not.

Windows XP and later versions of Windows do not use any .dbg symbol files. See [Symbols and Symbol Files](#) for details.

Mismatched Builds

One of the most common problems in debugging failures on a machine that is often updated is mismatched symbols from different builds. Three common causes of this problem are: pointing at symbols for the wrong build, using a privately built binary without the corresponding symbols, and using the uniprocessor hardware abstraction level (HAL) and kernel symbols on a multiprocessor machine. The first two are simply a matter of matching your binaries and symbols; the third can be corrected by renaming your hal*.dbg and ntkrnlmp.dbg to hal.dbg and ntoskrnl.dbg.

To find out what build of Windows is installed on the target computer, use the [vertarget \(Show Target Computer Version\)](#) command:

```
kd> vertarget
Windows XP Kernel Version 2505 UP Free x86 compatible
Built by: 2505.main.010626-1514
Kernel base = 0x804d0000 PsLoadedModuleList = 0x80548748
Debug session time: Mon Jul 02 14:41:11 2001
System Uptime: 0 days 0:04:53
```

Testing the Symbols

Testing the symbols is more difficult. It involves verifying a stack trace on the debugger and seeing if the debug output is correct. Here's one example to try:

```
kd> u videotpt!videoportfindadapter2
Loading symbols for 0xf2860000      videotpt.sys -> videotpt.sys

VIDEOPRT!VideoPortFindAdapter2:
f2856f42 55          push    ebp
f2856f43 8bec        mov     ebp,esp
f2856f45 81ecb8010000 sub    esp,0x1b8
f2856f4b 8b4518       mov     eax,[ebp+0x18]
f2856f4e 53          push    ebx
f2856f4f 8365f400     and    dword ptr [ebp-0xc],0x
f2856f53 8065ff00     and    byte ptr [ebp-0x1],0x0
f2856f57 56          push    esi
```

The **u** command unassembles the videoportfindadapter string in videotpt.sys. The symbols are correct on the debugger because common stack commands like **push** and **mov** show up on the stack. Most functions begin with an add, sub, or push operation using either the base pointer (ebp) or the stack pointer (esp).

It's usually obvious when the symbols aren't working correctly. Glintmp.sys doesn't have symbols in this example because a function isn't listed next to **Glintmp**:

```
kd> kb
Loading symbols for 0xf28d0000      videotpt.sys -> videotpt.sys
Loading symbols for 0xf9cdd000      glintmp.sys -> glintmp.sys
*** ERROR: Symbols could not be loaded for glintmp.sys
ChildEBP RetAddr  Args to Child
f29bf1b0 8045b5fa 00000001 0000a100 00000030 ntoskrnl!RtlpBreakWithStatusInstruction
f29bf1b0 8044904e 00000001 0000a100 00000030 ntoskrnl!KeUpdateSystemTime+0x13e
f29bf234 f28d1955 f9b7d000 ffafb2dc f9b7d000 ntoskrnl!READ_REGISTER ULONG+0x6
f29bf248 f9cde411 f9b7d000 f29bf2b0 f9ba0060 VIDEOPRT!VideoPortReadRegisterUlong+0x27
00000002 00000000 00000000 00000000 glintMP+0x1411 [No function listed.]
```

The wrong build symbols were loaded for this stack trace. Notice how there are no functions listed for the first two calls. This stack trace looks like a problem with win32k.sys drawing rectangles:

```

1: kd>
1: kd> kb [Local 9:50 AM]
Loading symbols for 0xf22b0000 agpcpq.sys -> agpcpq.sys

Useful Commands and Extensions

The following commands and extensions may be useful in tracking down symbol problems:

!lm (List Loaded Modules)

Lists all modules and gives the loading status of all symbols in these modules.

!dh image-header-base

Displays header information for a loaded image beginning at *image-header-base*.

.reload /n

Reloads all kernel symbols.

.reload [image-name]

(CDB or WinDbg only) Reloads symbols for the image *image-name*. If no *image-name* is specified, reloads symbols for all images. (It is necessary to reload symbols after the symbol path has been changed.)

!sym noisy

Turns on verbose mode for symbol loads. This can be used to get information about the module loads. See [Setting Symbol Options](#) for details.

.sympath [new-symbol-path]

Sets a new symbol path, or displays the current symbol path. See [Symbol Path](#) for details.

If the kernel symbols are correct, but you aren't getting a complete stack, the following commands may also be useful:

X *!

This will list the modules which currently have symbols loaded. This is useful if the kernel symbols are correct.

.reload /user

This will attempt to reload all user-mode symbols. This is needed while performing kernel debugging if symbols were loaded while one process was running, and a break later occurred in another process. In this case, the user-mode symbols from the new process will not be loaded unless this command is executed.

X wdmaud!*start*

This will list only the symbols in the **wdmaud** module whose names contain the "start" string. This has the advantage that it forces the reloading of all the symbols in **wdmaud**, but only displays those with "start" in them. (This means a shorter listing, but since there are always some symbols with "start" in them, there will be some verification that the load has taken place.)

One other useful technique for verifying symbols is unassemblying code. Most functions begin with an add, sub, or push operation using either the base pointer (**ebp**) or the stack pointer (**esp** or **sp**). Try unassemblying (**U Function**) some of the functions on the stack (from offset zero) to verify the symbols.

Network and Port Problems

Problems will occur with the symbol files and while connecting to the debugger. Here are a few things to keep in mind if you encounter problems:

- Determine which COM port the debug cable is connected to on the test system.
- Check the boot.ini settings of the test system. Look for the **/debug** switch and check the baud rate and COM port settings.
- Network problems can interfere with debugging if the symbols files are accessed through the network.
- .dll and .sys files with the same name (for example – `mga64.sys` and `mga64.dll`) will confuse the debugger if they aren't separated into the proper directories of the symbol tree.
- The kernel debugger doesn't always like replacing the build symbol files with private symbol files. Double check the symbol path and do a **.reloadFileName** on the misbehaving symbol. The **!d11s** command is sometimes useful.

Questions and Misconceptions

Q: I've successfully loaded symbols, but the stack seems to be wrong. Is the debugger broken?

A: Not necessarily. The most likely cause of your problem is that you've got incorrect symbols. Go through the steps outlined in this section to determine whether you've loaded valid symbols or not. Do not assume that because some things work you have valid symbols. For example, you very well may be able to execute **dd nt!ntbuildnumber** or **u nt!KeInitializeProcess** with incorrect symbols. Verify that they are correct using the procedures outlined above.

Q: Will the debugger still work with incorrect symbols?

A: Yes and no. Often you can get away with symbols that don't strictly match. For example, symbols from a previous Windows build will often work in certain cases, but there is no rule as to when this will work and when it will not.

Q: I'm stopped in the kernel debugger and I want to view symbols for my user-mode process. Can I do it?

A: Mostly. The support for this scenario is poor because the kernel debugger doesn't keep enough information around to track the module loads for each process, but there's a reasonable workaround. To load symbols for a user-mode module, execute a **.reload -user** command. This will load the user-mode modules for the current context.

Q: What does the following message mean?

```
*** WARNING: symbols checksum and timestamp is wrong 0x0036d6bf 0x0036ab55 for ntkrnlmp.exe
```

A: It means your symbols for ntkrnlmp.exe are wrong.

Matching Symbol Names

5/26/2017 • 1 min to read • [Edit Online](#)

In certain situations, the actual name of a symbol is replaced with an alternative form which can then result in symbol matching problems. This most commonly happens when changing between public and private symbols or when using MS-DOS compatibility 8.3 short names for files.

Public vs. Private Symbol Matching

Switching between public symbols and private symbols can sometimes cause symbol matching problems.

Typically, a public symbol and the corresponding private symbol have the same name with different symbol decorations. But in some cases, they may have entirely different names. In such cases, you might have to explicitly reference both names. For example, you could set up two breakpoints: one on the public symbol, and a second one on the private symbol. For more details, see [Public and Private Symbols](#).

MS-DOS Compatibility 8.3 Short Name Symbol Matching

Files that have very long names are sometimes given auto-generated MS-DOS compatibility 8.3 short names.

Depending on the tools and options used for creating symbol files and for debugging, the file name stored in the image's debug record can be either the long name or one of these short names. If the short names is used, this can cause symbol matching problems because the short name assigned is system dependent.

For example, suppose there are two files, Longfilename1.pdb and Longfilename2.pdb. If they are put in the same directory one will have an MS-DOS compatibility 8.3 name of Longfi~1.pdb and the other will be Longfi~2.pdb. If they are not put in the same directory they will both be Longfi~1.pdb. Thus, if the associated .pdb files are copied carelessly, the short filenames can change, causing symbol matching problems. For more details, see [File System References and Symbol Files](#).

Reading Symbols from Paged-Out Headers

5/31/2017 • 3 min to read • [Edit Online](#)

The kernel debugger must read the header for each loaded module's image in order to know which symbols correspond to that module.

If a module's header is paged out to disk, the debugger will not load symbols for this module. If this happens with a module that is essential to the debugging process, it can be a critical problem.

The following procedure can be used to solve this problem.

To acquire symbols for paged-out headers

1. Make a second copy of the kernel itself. It is probably easiest to put this on a network share.
2. Append the root directory of this share to the symbol path. See [Symbol Path](#) for the ways to change the symbol path.
3. Use the [.reload \(Reload Module\)](#) command.
4. Use the [!sym noisy](#) extension command to see more verbose output. If this is used, you will be able to see which symbols are loaded from the module images on the target computer, and which are loaded from the copy of the kernel modules.

This technique must be used with care, since the debugger has no way of verifying whether the file copies actually match the originals. So it is crucial that the version of Windows used on the network share matches the version used on the target computer.

This technique is only used for kernel-mode debugging. The operating system is capable of paging in any headers required during user-mode debugging (unless the disk holding the paging file is dismounted or otherwise inaccessible).

Here is an example of this technique being used:

```
kd> .reload
Connected to Windows XP 2268 x86 compatible target, ptr64 FALSE
Loading Kernel Symbols
.....Unable to read image header for dmload.sys at fe0be000 - NTSTATUS 0xC0000001
.....Unable to read image header for dmboot.sys at fda93000 - NTSTATUS 0xC0000001
.....Unable to read image header for fdc.sys at fd0c2000 - NTSTATUS 0xC0000001
..Unable to read image header for flpydisk.sys at fde4a000 - NTSTATUS 0xC0000001
.Unable to read image header for Fs_Rec.SYS at fe0c8000 - NTSTATUS 0xC0000001
.Unable to read image header for Null.SYS at fe2c4000 - NTSTATUS 0xC0000001
.....Unable to read image header for win32k.sys at a0000000 - NTSTATUS 0xC0000001
..Unable to read image header for dxg.sys at a0194000 - NTSTATUS 0xC0000001
.....Unable to read image header for ati2draa.dll at a01a4000 - NTSTATUS 0xC0000001
..Unable to read image header for ParVdm.SYS at fe116000 - NTSTATUS 0xC0000001
.....
Loading unloaded module list
.....
Loading User Symbols
Unable to retrieve the PEB address. This is usually caused
by being in the wrong process context or by paging
```

Notice that many images have inaccessible headers. Check the symbols from one of these files (in this example, `fs_rec.sys`):

```
kd> x fs_rec!*
*** ERROR: Module load completed but symbols could not be loaded for fs_rec.sys
```

These headers are apparently paged out. So you need to add the proper images to the symbol path:

```
kd> .sympath+ \\myserver\myshare\symbols\x86fre\symbols
Symbol search path is:
symsrv*symsrv.dll*c:\localcache*https://msdl.microsoft.com/download/symbols;\\myserver\myshare\symbols\x86fre\symbols

kd> .reload
Connected to Windows XP 2268 x86 compatible target, ptr64 FALSE
Loading Kernel Symbols
.....Unable to read image header for dmload.sys at fe0be000 - NTSTATUS 0xC0000001
.....Unable to read image header for dmboot.sys at fda93000 - NTSTATUS 0xC0000001
.....Unable to read image header for fdc.sys at fd0fc2000 - NTSTATUS 0xC0000001
.....Unable to read image header for flpydisk.sys at fde4a000 - NTSTATUS 0xC0000001
.Unable to read image header for Fs_Rec.SYS at fe0c8000 - NTSTATUS 0xC0000001
.Unable to read image header for Null.SYS at fe2c4000 - NTSTATUS 0xC0000001
.....Unable to read image header for win32k.sys at a0000000 - NTSTATUS 0xC0000001
..Unable to read image header for dxg.sys at a0194000 - NTSTATUS 0xC0000001
.....Unable to read image header for ati2draa.dll at a01a4000 - NTSTATUS 0xC0000001
..Unable to read image header for ParVdm.SYS at fe116000 - NTSTATUS 0xC0000001
.....
Loading unloaded module list
.....
Loading User Symbols
Unable to retrieve the PEB address. This is usually caused
by being in the wrong process context or by paging
```

The same warnings have appeared, but the symbols themselves are now accessible:

```
kd> x fs_Rec!*
fe0c8358  Fs_Rec!_imp__allmul
fe0c8310  Fs_Rec!_imp__IoCreateDevice
fe0c835c  Fs_Rec!_imp__allshr
.....
fe0c8360  Fs_Rec!ntoskrnl_NULL_THUNK_DATA
fe0c832c  Fs_Rec!_imp__KeSetEvent
fe0c9570  Fs_Rec!_NULL_IMPORT_DESCRIPTOR
```

[Send comments about this topic to Microsoft](#)

Mapping Symbols When the PEB is Paged Out

5/31/2017 • 3 min to read • [Edit Online](#)

To load symbols, the debugger looks at the list of modules loaded by the operating system. The pointer to the user-mode module list is one of the items stored in the process environment block (PEB).

To reclaim memory, the Memory Manager may page out user-mode data to make space for other process or kernel mode components. The user-mode data that is paged out may include the PEB data structure. Without this data structure, the debugger cannot determine for which images to load symbols.

Note This affects symbol files only for the user-mode modules. Kernel-mode modules and symbols are not affected, as they are tracked in a different list.

Suppose a user-mode module is mapped into the current process and you want to fix the symbols for it. Find any address in the range of virtual addresses of the module. For example, suppose a module is mapped into a virtual address range that contains the address 7f78e9e000F. Enter the following command.

```
3: kd> !vad 7f78e9e000F 1
```

The command output displays information about the virtual address descriptor (VAD) for the module. The command output also includes a Reload command string that you can use to load the symbols for the module. The Reload command string includes the starting address (000007f7`8e9e0000) and size (32000) of the notepad module.

```
VAD @ ffffffa80056fb960
...
Reload command: .reload notepad.exe=000007f7`8e9e0000,32000
```

To load the symbols, enter the command that was given in the Reload command string.

```
.reload notepad.exe=000007f7`8e9e0000,32000
```

Here is another example that uses a slightly different technique. The example demonstrates how to use the **!vad** extension to map symbols when the PEB is paged out. The basic idea is to find the starting address and size of the relevant DLL so that you can then use the **.reload** command to load the necessary symbols. Suppose that the address of the current process is 0xE0000126`01BA0AF0 and you want to fix the symbols for it. First, use the **!process** command to obtain the virtual address descriptor (VAD) root address:

```
kd> !process e000012601ba0af0 1
PROCESS e000012601ba0af0
SessionId: 2 Cid: 0b50 Peb: 6fbffffde000 ParentCid: 0efc
DirBase: 079e8461 ObjectTable: e000000600fbceb0 HandleCount: 360.
Image: explorer.exe
VadRoot e000012601a35e70 Vads 201 Clone 0 Private 917. Modified 2198. Locked 0.
...
```

Then use the **!vad** extension to list the VAD tree associated with the process. Those VADs labeled "EXECUTE_WRITECOPY" belong to code modules.

```
kd> !vad e000012601a35e70
VAD      level      start      end      commit
...
e0000126019f9790 ( 6)      3fff0      3fff7      -1 Private      READONLY
e000012601be1080 ( 7)      37d9bd30 37d9bd3e      2 Mapped  Exe  EXECUTE_WRITECOPY  <-- these are DLLs
e000012600acd970 ( 5)      37d9bec0 37d9bece      2 Mapped  Exe  EXECUTE_WRITECOPY
e000012601a5cba0 ( 7)      37d9c910 37d9c924      2 Mapped  Exe  EXECUTE_WRITECOPY
...
```

Then use the **!vad** extension again to find the starting address and size of the paged out memory which holds the DLL of interest. This confirms that you have found the correct DLL:

```
kd> !vad e000012601be1080 1
VAD @ e000012601be1080
  Start VPN:      37d9bd30  End VPN: 37d9bd3e  Control Area: e00001260197b8d0
  First ProtoPte: e0000006013e00a0  Last PTE ffffffff00000000  Commit Charge      2 (2.)
  Secured.Flink      0  Blink      0  Banked/Extend:      0
  File Offset      0
  ImageMap ViewShare EXECUTE_WRITECOPY
...
  File: \Windows\System32\ExplorerFrame.dll
```

The "Start VPN" field - in this case, 0x37D9BD30 - indicates the starting virtual page number. This must be converted to an actual address, by multiplying it by the page size. You can use the **? (Evaluate Expression)** command to multiply this value by 0x2000, which is the page size for the Itanium-based machine the example comes from.

```
kd> ? 37d9bd3e*2000
Evaluate expression: 7676040298496 = 0000006fb`37a7c000
```

Then the size of the range can be converted to bytes:

```
kd> ? 37d9bd3e-37d9bd30+1 <-- computes the number of pages
Evaluate expression: 15 = 00000000`0000000f
kd> ? f*2000
Evaluate expression: 122880 = 00000000`0001e000
```

So ExplorerFrame.dll starts at address 0x0000006Fb`37A7C000 and is 0x1E000 bytes large. You can load its symbols with:

```
kd> .reload /f ExplorerFrame.dll=6fb`37a7c000,1e000
```

Debugging User-Mode Processes Without Symbols

5/26/2017 • 1 min to read • [Edit Online](#)

It is important to have symbols on the faulting machine before starting the debugger for a user-mode failure. However, sometimes the debugger is started without symbols. If the problem is easily reproducible, you can just copy symbols and rerun. If, however, the problem may not occur again, some information can still be gleaned from the failure:

1. To figure out what the addresses mean, you'll need a computer which matches the one with the error. It should have the same platform (x86 or x64) and be loaded with the same version of Windows.
2. When you have the computer configured, copy the user-mode symbols and the binaries you want to debug onto the new machine.
3. Start CDB or WinDbg on the symbol-less machine.
4. If you don't know which application failed on the symbol-less machine, issue an **| (Process Status)** command. If that doesn't give you a name, break into KD on the symbol-less machine and do a **!process 0 0**, looking for the process ID given by the CDB command.
5. When you have the two debuggers set up -- one with symbols which hasn't hit the error, and one which has hit the error but is without symbols -- issue a **k (Display Stack Backtrace)** command on the symbol-less machine.
6. On the machine with symbols, issue a **u (Unassemble)** command for each address given on the symbol-less stack. This will give you the stack trace for the error on the symbol-less machine.
7. By looking at a stack trace you can see the module and function names involved in the call.

Debugging Performance-Optimized Code

5/26/2017 • 3 min to read • [Edit Online](#)

Microsoft has certain techniques that it uses to re-arrange compiled and linked code so that it executes with more efficiency. These techniques optimize the component for memory hierarchies, and are based on training scenarios.

The resulting optimization reduces paging (and page faults), and increases spatial locality between code and data. It addresses a key performance bottleneck that would be introduced by poor positioning of the original code. A component that has gone through this optimization may have its code or data block within a function moved to different locations of the binary.

In modules that have been optimized by these techniques, the locations of code and data blocks will often be found at memory addresses different than the locations where they would reside after normal compilation and linking. Furthermore, functions may have been split into many non-contiguous blocks, in order that the most commonly-used code paths can be located close to each other on the same pages.

Therefore, a function (or any symbol) plus an offset will not necessarily have the same meaning it would have in non-optimized code.

Debugging Performance-Optimized Code

When debugging, you can see if a module has been performance-optimized by using the **!lmi** extension command on any module for which symbols have been loaded:

```
0:000> !lmi ntdll
Loaded Module Info: [ntdll]
    Module: ntdll
    Base Address: 77f80000
    Image Name: ntdll.dll
    Machine Type: 332 (I386)
    Time Stamp: 394193d2 Fri Jun 09 18:03:14 2000
    CheckSum: 861b1
    Characteristics: 230e stripped perf
    Debug Data Dirs: Type Size      VA  Pointer
                      MISC 110,      0,    76c00 [Data not mapped]
    Image Type: DBG      - Image read successfully from symbol server.
                      c:\symbols\ dll\ntdll.dbg
    Symbol Type: DIA PDB - Symbols loaded successfully from symbol server.
                      c:\symbols\ dll\ntdll.pdb
```

In this output, notice the term **perf** on the "Characteristics" line. This indicates that this performance optimization has been applied to ntdll.dll.

The debugger is able to understand a function or other symbol without an offset; this allows you to set breakpoints on functions or other labels without any problem. However, the output of a disassembly operation may be confusing, because this disassembly will reflect the changes made by the optimizer.

Since the debugger will try to stay close to the original code, you might see some amusing results. The rule of thumb when working with performance-optimized codes is simply that you cannot perform reliable address arithmetic on optimized code.

Here is an example:

```

kd> b1
0 e f8640ca6      0001 (0001) tcpip!IPTransmit
1 e f8672660      0001 (0001) tcpip!IPFragment

kd> u f864b4cb
tcpip!IPTransmit+e48:
f864b4cb f3a4      rep     movsb
f864b4cd 8b75cc    mov     esi,[ebp-0x34]
f864b4d0 8b4d10    mov     ecx,[ebp+0x10]
f864b4d3 8b7da4    mov     edi,[ebp-0x5c]
f864b4d6 8bc6      mov     eax,esi
f864b4d8 6a10      push    0x10
f864b4da 034114    add    eax,[ecx+0x14]
f864b4dd 57        push    edi

```

You can see from the breakpoint list that the address of **IPTransmit** is 0xF8640CA6.

When you unassemble a section of code within this function at 0xF864B4CB, the output indicates that this is 0xE48 bytes past the beginning of the function. However, if you subtract the base of the function from this address, the actual offset appears to be 0xA825.

What is happening is this: The debugger is indeed showing a disassembly of the binary instructions beginning at 0xF864B4CB. But instead of computing the offset by simple subtraction, the debugger displays -- as best it can -- the offset to the function entry as it existed in the original code before the optimizations were performed. That value is 0xE48.

On the other hand, if you try to look at **IPTransmit**+0xE48, you will see this:

```

kd> u tcpip!iptransmit+e48
tcpip!ARPTransmit+d8:
f8641aee 0856ff    or     [esi-0x1],dl
f8641af1 75fc      jnz    tcpip!ARPTransmit+0xd9 (f8641aef)
f8641af3 57        push   edi
f8641af4 e828eeffff call   tcpip!ARPSendData (f8640921)
f8641af9 5f        pop    edi
f8641afa 5e        pop    esi
f8641afb 5b        pop    ebx
f8641afc c9        leave

```

What is happening here is that the debugger recognizes the symbol **IPTransmit** as equivalent to the address 0xF8640CA6, and the command parser performs a simple addition to find that 0xF8640CA6 + 0xE48 = 0xF8641AEE. This address is then used as the argument for the **u (Unassemble)** command. But once this location is analyzed, the debugger discovers that this is not **IPTransmit** plus an offset of 0xE48. Indeed, it is not part of this function at all. Rather, it corresponds to the function **ARPTransmit** plus an offset of 0xD8.

The reason this happens is that performance optimization is not reversible through address arithmetic. While the debugger can take an address and deduce its original symbol and offset, it does not have enough information to take a symbol and offset and translate it to the correct address. Consequently, disassembly is not useful in these cases.

Using AgeStore

5/26/2017 • 2 min to read • [Edit Online](#)

AgeStore is a tool that deletes files in a directory or directory tree, based on their last access dates. Its primary use is for removing old files from the downstream store used by a symbol server or a source server, in order to conserve disk space. It can also be used as a general file deletion tool.

AgeStore can delete all files in a single directory (the *target directory*), or in all the directories within a tree (the *target tree*). The *-s* option indicates that an entire tree is to be targeted.

There are three ways to specify which files within the target directory or target tree are to be deleted. The *agestore -date=Month-Day-Year* command deletes all files that were last accessed prior to the specified date. The *agestore -days=NumberOfDays* command deletes all files that were last accessed more than the specified number of days ago. The *agestore -size=SizeRemaining* command deletes all files in the target directory or target tree, beginning with the least-recently-accessed files, until the total size of the remaining files is less than or equal to *SizeRemaining*.

For example, the following command deletes all files in C:\MyDir that were last accessed prior to January 7, 2008:

```
agestore c:\mydir -date=01-07-2008
```

The following command deletes all files in the directory tree subordinate to C:\symbols\downstreamstore that were last accessed over thirty days ago:

```
agestore c:\symbols\downstreamstore -days=30 -s
```

The following command deletes files in the directory tree subordinate to C:\symbols\downstreamstore, beginning with those accessed longest ago, until the total size of all files in this tree is less than or equal to 50,000 bytes:

```
agestore c:\symbols\downstreamstore -size=50000 -s
```

The *-l* option causes AgeStore to delete no files, but merely to list all the files that would be deleted without this option. Before you use any AgeStore command you should run the intended command with the *-l* option added, to verify that it will delete exactly those files you intend it to delete.

For the complete command line syntax, see [AgeStore Command-Line Options](#).

Running AgeStore on Windows Vista and Later

Because AgeStore deletes files based on the last time that they were accessed, it can run successfully only if your file system stores Last Access Time (LAT) data. In the NTFS file system, LAT data storage can be either enabled or disabled. If it is disabled, AgeStore will not run, but will display the following error message instead:

```
Last-Access-Time support is disabled on this computer.  
Please read the documentation for more details.
```

In Windows 2000, Windows XP, and Windows Server 2003, LAT data storage is enabled by default. In Windows Vista and later versions of Windows, LAT data storage is disabled by default, and therefore AgeStore will not run unless you first enable this data.

In Windows Vista and later versions of Windows, you can use the FSUtil (Fsutil.exe) tool to enable the gathering of LAT data. From a Command Prompt window, issue the following command:

```
fsutil behavior set disablelastaccess 0
```

To disable the gathering of LAT data, using the following command:

```
fsutil behavior set disablelastaccess 1
```

These changes take effect after the next restart of Windows.

The FAT32 file system always stores LAT information (although only the date, and not the time, are stored). Therefore, AgeStore works with FAT32 file systems. However, since AgeStore will not run when the NTFS LAT is disabled, you must enable NTFS LAT even if your file system is FAT32.

AgeStore Command-Line Options

5/31/2017 • 3 min to read • [Edit Online](#)

The AgeStore command line uses the following syntax. The parameters can be included in any order.

```
agestore [PathSpec] -date=Month-Day-Year Options
agestore [PathSpec] -days=NumberOfDays Options
agestore [PathSpec] -size=SizeRemaining Options
agestore [PathSpec] -size Options
agestore -?
```

Parameters

PathSpec

Specifies the target directory in which files are to be deleted. If the **-s** option is used, *PathSpec* specifies the root directory of the target tree in which files are to be deleted. *PathSpec* may be the absolute or relative path of a directory on the local computer, or a UNC path. If *PathSpec* contains spaces, it must be enclosed in quotation marks. If *PathSpec* is omitted, AgeStore uses the current working directory.

-date=Month-Day-Year

Specifies the cutoff date for deleting files. All files that were last accessed prior to the specified date will be deleted. The date must be specified in the format Month-Day-Year, with hyphens between the month and day and between the day and the year. Leading zeros in *Month* and *Day* are optional. The year can be specified with two digits or four. Thus you can indicate the date of January 5, 2008 as 01-05-2008 or 1-5-08.

-days=NumberOfDays

Specifies the cutoff date and time for deleting files. All files that were last accessed prior to the specified number of days ago will be deleted. *NumberOfDays* specifies an integer number of 24-hour days. For example, if the specifier **-days=3** is used at 6:00 PM on February 17, 2008, all files last accessed prior to 6:00 PM on February 14, 2008 will be deleted.

-size=SizeRemaining

Specifies the total size of the files that should remain after the deletion, in bytes. When this switch is used, AgeStore deletes files in the target directory or target tree, beginning with the files accessed least recently, until the total size of the remaining files is less than or equal to *SizeRemaining*. When the **-s** option is used, AgeStore targets an entire directory tree, and *SizeRemaining* specifies the total size of files that should remain in this entire directory tree after deletion.

-size

Causes AgeStore to list the total size of all files in the target directory or target tree. No files are deleted.

Options

Any combination of the following options.

-l

Causes AgeStore not to delete any files, but merely to list all the files that would be deleted if this same command were run without the **-l** option.

-s

Causes AgeStore to treat the entire directory tree subordinate to *PathSpec* as the target. When the **-s** option is not used, the directory specified by *PathSpec* becomes the target directory in which files will be deleted. When the **-s** option is used, the directory specified by *PathSpec* and all subdirectories under it become the target tree in which files will be deleted.

-k

Causes AgeStore to keep any empty subdirectories. If this option is not used, AgeStore deletes the target directory if it is completely empty after the command runs. If the **-s** option is used without the **-k** option, all empty directories in the target directory tree will be deleted after AgeStore has completed its file deletion -- even the root directory itself, if it becomes empty. If there are directories in this tree that happen to be already empty before AgeStore runs, AgeStore deletes these directories as well. However, if the AgeStore command results in no file deletion (for example, if the **-size=SizeRemaining** parameter specifies a size larger than the total size of all files in the target tree), empty directories are not deleted. If the **-s** option is not used, empty directories are never deleted, and the **-k** option is ignored.

-q

Quiet mode. If this option is not included, AgeStore lists all files as they are deleted.

-y

Suppresses the **(y/n)** prompt. If this option is not used, AgeStore prompts you with an "Are you sure?" prompt before deleting any files.

-?

Displays help text for the AgeStore command line.

Additional Information

For more information about the AgeStore tool, see [Using AgeStore](#).

[Send comments about this topic to Microsoft](#)

DBH

5/26/2017 • 1 min to read • [Edit Online](#)

The DBH tool (dbh.exe) is a command-line tool that displays information about the contents of a symbol file.

DBH exposes the functionality of the DbgHelp API (dbghelp.dll) through a convenient command-line interface. Therefore, its behavior may change as DbgHelp is updated. The source code for one version of DBH is available in the Windows Software Development Kit (SDK) for Windows 8.

This section includes:

[Using DBH](#)

[Additional DBH Examples](#)

DBH Command-Line Options

[DBH Commands](#)

For more information about the DbgHelp API, see the Debug Help Library documentation, which is installed as part of Debugging Tools for Windows if you perform a custom install and select the **SDK** feature and its subfeatures.

[Send comments about this topic to Microsoft](#)

Using DBH

5/26/2017 • 3 min to read • [Edit Online](#)

DBH is a command-line tool that exposes many of the functions in the DbgHelp API (dbghelp.dll). It can display information about the contents of a symbol file, display specific details of the symbols in the file, and search through the file for symbols matching various criteria.

The functionality provided by DBH is similar to that provided within WinDbg, KD, and CDB by commands such as [x \(Examine Symbols\)](#).

Running DBH in Interactive Mode

You start DBH with a simple command line, on which you specify the target module whose symbols you wish to investigate. A target module can be an EXE program or a PDB symbol file. You can also specify a process ID (PID) to investigate. See [DBH Command-Line Options](#) for the full syntax.

When DBH starts, it loads the symbols for the specified module, and then presents you with a prompt at which you can type a variety of commands. See [DBH Commands](#) for a list of available commands.

For example, the following sequence starts DBH by specifying the target process with process ID 4672, then executes the **enum** command at the DBH prompt to display symbols matching a specific pattern, and then executes the **q** command to quit DBH:

```
C:\> dbh -p:4672
        400000 : TimeTest
        77820000 : ntdll
        77740000 : kernel32

pid:4672 mod:TimeTest[400000]: enum TimeTest!ma*

index      address      name
 1          42cc56 :  main
 3          415810 :  malloc
 5          415450 : mainCRTStartup

pid:4672 mod:TimeTest[400000]: q

goodbye
```

Running DBH in Batch Mode

If you wish to run only a single DBH command, you can specify it at the end of the command line. This causes DBH to start, load the specified module, run the specified command, and then exit.

For example, the previous example could be replaced with a single command line:

```
C:\> dbh -p:4672 enum TimeTest!ma*
        400000 : TimeTest
        77820000 : ntdll
        77740000 : kernel32

index      address      name
 1          42cc56 :  main
 3          415810 :  malloc
 5          415450 : mainCRTStartup
```

This method of running DBH is called *batch mode*, because it can be easily used in batch files. This version of the

command line can also be followed by a pipe (|) which redirects the DBH output to another program.

Specifying the Target

DBH can select a target in three ways: by the process ID of a running process, by the name of the executable, or by the name of the symbol file. For example, if there is exactly one instance of MyProg.exe currently running, with process ID 1234, then the following commands are almost equivalent:

```
C:\> dbh -v -p:1234
C:\> dbh -v c:\mydir\myprog.exe
C:\> dbh -v c:\mydir\myprog.pdb
```

One difference between these commands is that when you start DBH by specifying the process ID, DBH uses the actual virtual addresses being used by this process. When you start DBH by specifying the executable name or the symbol file name, DBH assumes that the module's base address is a standard value (for example, 0x01000000). You can then use the **base** command to specify the actual base address, thus shifting the addresses of all the symbols in the module.

DBH does not attach to the target process in the way that a debugger does. DBH cannot cause a process to begin or end, nor can it alter how that process runs. For DBH to attach to a process by its process ID, the target process has to be running, but once DBH has been started the target process can be terminated and DBH will continue to access its symbols.

Decorated and Undecorated Symbols

By default, DBH uses undecorated symbol names when displaying and searching for symbols. If you turn off the **SYMOPT_UNDNAME** symbol option, or include the -d option on the DBH command line, decorations will be included.

For information on symbol decorations, see [Public and Private Symbols](#).

Exiting DBH

To exit DBH, use the **q** command at the DBH prompt.

[Send comments about this topic to Microsoft](#)

Additional DBH Examples

5/31/2017 • 7 min to read • [Edit Online](#)

Here are additional examples of commands that can be issued at the DBH prompt.

Displaying Private Symbols and Public Symbols

If the target is a full symbol file, then each public symbol appears twice in the file: in the public symbol table, and in the private symbol data. The copy in the public symbol table often contains various decorations (prefixes and suffixes). For details, see [Public and Private Symbols](#).

DBH can display information about this symbol from the private symbol data, from the public symbol table without decorations, and from the public symbol table with decorations. Here is an example in which all three of these are displayed, using the command **addr 414fe0** each time.

The first time this command appears in this example, DBH uses the default symbol options, so the resulting information comes from the private symbol data. Note that this information includes the address, size, and data type of the function **fgets**. Then, the command **symopt +4000** is used, which turns on the **SYMOPT_PUBLICS_ONLY** option. This causes DBH to ignore the private symbol data, and therefore when the **addr 414fe0** command is run the second time, DBH uses the public symbol table, and no size or data type information is shown for the function **fgets**. Finally, the command **symopt -2** is used, turning off the **SYMOPT_UNDNAME** option and causing DBH to include decorations. When the **addr 414fe0** runs this final time, it shows the decorated version of the function name, **_fgets**.

```

pid:4308 mod:TimeTest[400000]: addr 414fe0

fgets
  name : fgets
  addr : 414fe0
  size : 113
  flags : 0
  type : 7e
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagFunction (5)
  index : 7d

pid:4308 mod:TimeTest[400000]: symopt +4000

Symbol Options: 0x10c13
Symbol Options: 0x14c13

pid:4308 mod:TimeTest[400000]: addr 414fe0

fgets
  name : fgets
  addr : 414fe0
  size : 0
  flags : 0
  type : 0
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagPublicSymbol (a)
  index : 7f

pid:4308 mod:TimeTest[400000]: symopt -2

Symbol Options: 0x14c13
Symbol Options: 0x14c11

pid:4308 mod:TimeTest[400000]: addr 414fe0

_fgets
  name : _fgets
  addr : 414fe0
  size : 0
  flags : 0
  type : 0
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagPublicSymbol (a)
  index : 7f

```

If the **-d** command-line option had been used, the results would have shown the decorated public name from the beginning.

Determining the Decorations of a Specific Symbol

DBH can determine the decorations on a specific symbol. This can be useful when used in conjunction with a program that requires symbols to be specified with their decorations, such as [PDBCopy](#).

For example, suppose you know that the symbol file mysymbols.pdb contains a symbol whose undecorated name is **MyFunction1**. To find the decorated name, use the following procedure.

First, start DBH without the -d command-line option, and then use the symopt +4000 command so that all information comes from the public symbol table:

```
C:\> dbh c:\mydir\mysymbols.pdb
mysymbols [1000000]: symopt +4000
Symbol Options: 0x10c13
Symbol Options: 0x14c13
```

Next, use the **name** command or the **enum** command to display the address of the desired symbol:

```
mysymbols [1000000]: enum myfunction1
index      address      name
2ab        102cb4e :  MyFunction1
```

Now use symopt -2 to make symbol decorations visible, and then use the **addr** command with the address of this symbol:

```
mysymbols [1000000]: symopt -2
Symbol Options: 0x14c13
Symbol Options: 0x14c11
mysymbols [1000000]: addr 102cb4e
_MyFunction1@4
  name : _InterlockedIncrement@4
  addr : 102cb4e
  size : 0
  flags : 0
  type : 0
  modbase : 1000000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagPublicSymbol (a)
  index : 2ab
```

This reveals that the decorated name of the symbol is **_MyFunction1@4**.

Decoding Symbol Decorations

The **undec** command can be used to reveal the meaning of C++ symbol decorations. In the following example, the decorations attached to ??_C@_03GGCAPAJC@Sep?\$AA@ are decoded to indicate that it is a string:

```
dbh: undec ??_C@_03GGCAPAJC@Sep?$AA@
??_C@_03GGCAPAJC@Sep?$AA@ =
`string'
```

The following examples decode the decorations attached to three function names, revealing their prototypes:

```

dbh: undec ?gcontext@@3_KA

?gcontext@@3_KA =
unsigned __int64 gcontext

dbh: undec ?pathcpy@@YGXPAGPBG1K@Z

?pathcpy@@YGXPAGPBG1K@Z =
void __stdcall pathcpy(unsigned short *,unsigned short const *,unsigned short const *,unsigned long)

dbh: undec ?_set_new_handler@@YAP6AHI@ZP6AHI@Z@Z

?_set_new_handler@@YAP6AHI@ZP6AHI@Z@Z =
int (__cdecl* __cdecl _set_new_handler(int (__cdecl*)(unsigned int)))(unsigned int)

```

The **undec** command does not display information about initial underscores, the prefix **__imp_**, or trailing "@*address*" decorations, which are commonly found attached to function names.

You can use the **undec** command with any string, not just the name of a symbol in the currently loaded module.

Sorting a List of Symbols by Address

If you simply want a list of symbols, sorted in address order, you can run DBH in batch mode and pipe the results to a **sort** command. The address values typically begin in the 18th column of each line, so the following command sorts the results by address:

```
dbh -p:4672 enum mymodule!* | sort /+18
```

Displaying Source Line Information

When you use a full symbol file, DBH can display source line information. This does not require access to any source files, since this information is stored in the symbol files themselves.

Here, the **line** command displays the hexadecimal address of the binary instructions corresponding to the specified source line, and it displays the symbols associated with that line. (In this example, there are no symbols associated with the line.)

```

dbh [1000000]: line myprogram.cpp#767

file : e:\mydirectory\src\myprogram.cpp
line : 767
addr : 1006191
key : 0000000000000000
disp : 0

```

Here, the **srclines** command displays the object files associated with the specified source line:

```

dbh [1000000]: srclines myprogram.cpp 767

0x1006191: e:\mydirectory\objchk\amd64\myprogram.obj
line 767 e:\mydirectory\src\myprogram.cpp

```

Note that the output of **srclines** is similar to that of the [In \(List Nearest Symbols\)](#) debugger command.

Displaying a Data Type

The **type** command can be used to display information about a data type. Here it displays data about the **CMDPROC** type:

```
dbh [1000000]: type CMDPROC

  name : CMDPROC
  addr :          0
  size : 8
  flags : 0
  type : c
  modbase : 1000000
  value :          0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagTypedef (11)
  index : c
```

The value listed after "tag" specifies the nature of this data type. In this case, **SymTagTypedef** indicates that this type was defined using a **typedef** statement.

Using Imaginary Symbols

The **add** command can add an imaginary symbol to the loaded module. The actual symbol file is not altered; only the image of that file in DBH's memory is changed.

The **add** command can be useful if you wish to temporarily override which symbols are associated with a given address range. In the following example, a portion of the address range associated with **MyModule!main** is overridden by the imaginary symbol **MyModule!magic**.

Here is how the module appears before the imaginary symbol is added. Note that the **main** function begins at 0x0042CC56, and has size 0x42B. So when the **addr** command is used with the address 0x0042CD10, it recognizes this address as lying within the boundaries of the **main** function:

```
pid:6040 mod:MyModule[400000]: enum timetest!ma*
```

```
index      address      name
 1          42cc56 :  main
 3          415810 :  malloc
 5          415450 : mainCRTStartup
```

```
pid:6040 mod:MyModule[400000]: addr 42cc56
```

```
main
  name : main
  addr : 42cc56
  size : 42b
  flags : 0
  type : 2
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagFunction (5)
  index : 1
```

```
pid:6040 mod:MyModule[400000]: addr 42cd10
```

```
main+ba
  name : main
  addr : 42cc56
  size : 42b
  flags : 0
  type : 2
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagFunction (5)
  index : 1
```

Now the symbol **magic** is added at the address 0x0042CD00, with size 0x10 bytes. When the **enum** command is used, the high bit in the index is set, showing that this is an imaginary symbol:

```
pid:6040 mod:MyModule[400000]: add magic 42cd00 10
```

```
pid:6040 mod:MyModule[400000]: enum timetest!ma*
```

```
index      address      name
 1          42cc56 :  main
 3          415810 :  malloc
 5          415450 : mainCRTStartup
80000001      42cd00 :  magic
```

When the **addr** command is used, it looks for any symbols whose ranges include the specified address. Since this search begins with the specified address and runs backward, the address 0x004CD10 is now associated with **magic**. On the other hand, the address 0x004CD40 is still associated with **main**, because it lies outside the range of the **magic** symbol. Note also that the tag **SymTagCustom** indicates an imaginary symbol:

```
pid:6040 mod:MyModule[400000]: addr 42cd10
```

```
magic+10
  name : magic
  addr : 42cd00
  size : 10
  flags : 1000
  type : 0
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagCustom (1a)
  index : 80000001
```

```
pid:6040 mod:MyModule[400000]: addr 42cd40
```

```
main+ea
  name : main
  addr : 42cc56
  size : 42b
  flags : 0
  type : 2
modbase : 400000
  value : 0
  reg : 0
  scope : SymTagNull (0)
  tag : SymTagFunction (5)
  index : 1
```

Finally, the **del** command can delete the symbol **magic**, returning all the symbols to their original ranges:

```
pid:6040 mod:MyModule[400000]: del magic
```

```
pid:6040 mod:MyModule[400000]: enum timetest!ma*
```

index	address	name
1	42cc56	main
3	415810	malloc
5	415450	mainCRTStartup

DBH Command-Line Options

5/31/2017 • 1 min to read • [Edit Online](#)

The DBH command line uses the following syntax.

```
dbh [Options] -p:PID [Command]  
dbh [Options] ExecutableName [Command]  
dbh [Options] SymbolFileName [Command]  
dbh -?  
dbh -??
```

Parameters

-p:PID

Specifies the process ID of the process whose symbols are to be loaded.

ExecutableName

Specifies the executable file whose symbols are to be loaded, including the file name extension (usually .exe or .sys). You should include a relative or absolute directory path; if no path is included, the current working directory is assumed. If the specified file is not found in this location, DBH searches for it using **SymLoadModuleEx**.

SymbolFileName

Specifies the symbol file whose symbols are to be loaded, including the file name extension (.pdb or .dbg). You should include a relative or absolute directory path; if no path is included, the current working directory is assumed.

Options

Any combination of the following options.

-d

Causes decorated names to be used when displaying symbols and searching for symbols. When this option is used, **SYMOPT_PUBLICS_ONLY** is turned on, and both **SYMOPT_UNDNAME** and **SYMOPT_AUTO_PUBLICS** are turned off. This is equivalent to issuing the command **symopt +4000** followed by **symopt -10002** after DBH is running.

-s:Path

Sets the symbol path to the specified *Path* value.

-n

Turns on *noisy symbol loading*. Additional information is displayed about the search for symbols. The name of each symbol file is displayed as it is loaded. If the debugger cannot load a symbol file, it displays an error message. Error messages for .pdb files are displayed in text. Error messages for .dbg files are in the form of an error code, explained in the *winerror.h* file. Not all of these messages are useful, but some of them may be helpful to analyze why a symbol file cannot be found or matched. If an image file is loaded solely to recover symbolic header information, this is displayed as well.

Command

Causes DBH to run, execute the specified *Command*, and then exit. For a list of possible commands, see [DBH Commands](#).

-?

Displays help text for the DBH command line.

-??

Displays help text for the DBH command line, and displays a list of all DBH commands.

DBH Commands

5/26/2017 • 8 min to read • [Edit Online](#)

From the DBH command line, you can use a variety of commands to analyze symbols and symbol files.

The following table lists the commands that control the DBH options and perform other basic tasks.

COMMAND	EFFECT
verbose [on off]	Turns verbose mode on or off. With no parameter, displays the current verbose mode setting.
sympath [Path]	Sets the symbol search path. With no parameter, displays the current symbol search path.
symopt Options symopt +Options symopt -Options symopt	Sets the symbol options. With no + or -, the value of <i>Options</i> replaces the current symbol options. If + or - is used, <i>Options</i> specifies the options to be added or removed; there must be a space before the + or - but no space after it. With no parameter, the current symbol options are displayed. When DBH is launched, the default value of all the symbol options is 0x10C13. For a list of available options, see Setting Symbol Options .
help	Displays help text for the DBH commands.
quit	Quits the DBH program.

The following table lists the commands that load, unload, and rebase the target module. These commands cannot be used if DBH was started by specifying a process ID on the command line.

COMMAND	EFFECT
load File	Loads the specified module. <i>File</i> should specify the path, file name, and file name extension of either the executable file or the symbol file.
unload	Unloads the current module.
base Address	Sets the default base address to the specified value. All symbol addresses will be determined relative to this base address.

The following table lists the commands that search for files and display directory information.

COMMAND	EFFECT
findex <i>File Path</i>	Locates the specified executable file in the specified path, using the FindExecutableImage routine.
finddbg <i>File Path</i>	Locates the specified .dbg file in the specified path. Including the .dbg extension is optional.
dir <i>File Path</i>	Locates the specified file in the specified path or in any subdirectory under this path, using the EnumDirTree routine.
srchtree <i>Path File</i>	Locates the specified file in the specified path or in any subdirectory under this path, using the SearchTreeForFile routine. This command is the same as dir , except that the parameters are reversed.
ffpath <i>File</i>	Finds the specified file in the current symbol path.

The following table lists the commands that parse the module list and control the default module. The default module and its base address are displayed on the DBH prompt.

COMMAND	EFFECT
mod <i>Address</i>	Changes the default module to the module with the specified base address.
refresh	Refreshes the module list.
omap	Displays the module OMAP structures.
epmod <i>PID</i>	Enumerates all the modules loaded for the specified process. <i>PID</i> specifies the process ID of the desired process.
info	Displays information about the currently loaded module.
obj <i>Mask</i>	Lists all object files associated with the default module that match the specified pattern. <i>Mask</i> may contain a variety of wildcard characters and specifiers; see String Wildcard Syntax for details.
src <i>Mask</i>	Lists all source files associated with the default module that match the specified pattern. <i>Mask</i> may contain a variety of wildcard characters and specifiers; see String Wildcard Syntax for details.

COMMAND	EFFECT
enummod	Enumerates all loaded modules. There is always at least one module, unless DBH is running without a target, in which case there are none.

The following table lists the commands that display and search for symbols.

COMMAND	EFFECT
enum <i>Module!Symbol</i>	Enumerates all symbols matching the specified module and symbol. <i>Module</i> specifies the module to search (without the file name extension). <i>Symbol</i> specifies a pattern that the symbol must contain. Both <i>Module</i> and <i>Symbol</i> may contain a variety of wildcard characters and specifiers; see String Wildcard Syntax for details.
enumaddr <i>Address</i>	Enumerates all symbols associated with the specified address.
addr <i>Address</i>	Displays detailed information about the symbols associated with the specified address.
name <i>[Module!]Symbol</i>	Displays detailed information about the specified symbol. An optional <i>Module</i> specifier may be included. Wildcards should not be used, because if multiple symbols match the pattern, name only displays the first of them.
next <i>[Module!]Symbol</i> next <i>Address</i>	Displays detailed information about the next symbol after the specified symbol or address. If a symbol is specified by name, an optional <i>Module</i> specifier may be included, but wildcards should not be used.
prev <i>[Module!]Symbol</i> prev <i>Address</i>	Displays detailed information about the first symbol previous to the specified symbol or address. If a symbol is specified by name, an optional <i>Module</i> specifier may be included, but wildcards should not be used.
line <i>File#LineNumber</i>	Displays the hexadecimal address of the binary instruction associated with the specified source line, and any symbols associated with this line. Also sets the current line number equal to the specified line number. <i>File</i> specifies the name of the source file, and <i>LineNumber</i> specifies the line number within that file; these should be separated with a number sign (#).
srclines <i>File LineNum</i>	Displays the object files associated with the specified source line, and the hexadecimal address of the binary instruction associated with this line. Does not change the current line number. <i>File</i> specifies the name of the source file, and <i>LineNumber</i> specifies the line number within that file; these should be separated with a space.

COMMAND	EFFECT
laddr <i>Address</i>	Displays the source file and line number corresponding to the symbol located at the specified address.
linenext	Increments the current line number, and displays information about the new line number.
lineprev	Decrements the current line number, and displays information about the new line number.
locals <i>Function</i> [<i>Mask</i>]	Displays all local variables contained within the specified function. If <i>Mask</i> is included, only those locals matching the specified pattern are displayed; see String Wildcard Syntax for details.
type <i>TypeName</i>	Displays detailed information about the specified data type. <i>TypeName</i> specifies the name of the data type (for example, <code>WSTRING</code>). If no type name matches this value, any matching symbol will be displayed. Unlike most DBH command parameters, <i>TypeName</i> is case-sensitive.
elines [<i>Source</i> [<i>Obj</i>]]	Enumerates all source lines matching the specified source mask and object mask. <i>Source</i> specifies the name of the source file, including the absolute path and file name extension. <i>Obj</i> specifies the name of the object file, including the relative path and file name extension. Both <i>Source</i> and <i>Obj</i> may contain a variety of wildcard characters and specifiers; see String Wildcard Syntax for details. If a parameter is omitted this is equivalent to using the asterisk (*) wildcard. If you do not wish to specify path information, prefix the file name with to indicate a wildcard path .
index <i>Value</i>	Displays detailed information about the symbol with the specified index value.
scope <i>Address</i> scope [<i>Module!</i>] <i>Symbol</i>	Displays detailed information about the parent of the specified symbol. The symbol may be specified by address or by name.
srch [mask = <i>Symbol</i>] [index = <i>Index</i>] [tag = <i>Tag</i>] [addr = <i>Address</i>] [globals]	Searches for all symbols that match the specified masks. <i>Symbol</i> specifies the symbol name. It should not include the module name, but it may contain wildcard characters and specifiers; see String Wildcard Syntax for details. <i>Index</i> specifies the hexadecimal address of a symbol to be used as the parent for the search. <i>Tag</i> specifies the hexadecimal symbol type classifier (SymTag <i>Xxx</i>) value that must match the symbol. <i>Address</i> specifies the address of the symbol. If globals is included, only global symbols will be displayed.

COMMAND	EFFECT
uw <i>Address</i>	Displays the unwind information for the function at the specified address.
dtag	Displays all the symbol type classifier (SymTag <i>Xxx</i>) values.
etypes	Enumerates all data types.
dump	Displays a complete list of all symbol information in the target file.

The following table lists the commands that relate to symbol servers and symbol stores.

COMMAND	EFFECT
home [<i>Path</i>]	Sets the home directory used by SymSrv and SrcSrv for the default downstream store. If the symbol path contains a reference to a symbol server that uses a default downstream store, then the sym subdirectory of the home directory will be used for the downstream store. With no parameter, home displays the current home directory.
srvpath <i>Path</i>	Tests whether the specified path is the path of a symbol store.
srvind <i>File</i>	Finds the symbol server index that corresponds to the specified file. The symbol server index is a unique value based on the contents of the file, regardless of whether it actually has been added to any symbol store. <i>File</i> should specify the file name and absolute path of the desired file.
fii <i>File</i>	Displays the symbol server indexes for the specified binary file and its associated files.
getfile <i>File Index</i>	Displays the file with the specified name and symbol server index. <i>File</i> specifies the name of the desired file; this should not include its path. <i>Index</i> specifies the symbol server index of the desired file. DBH uses the SymFindFileInPath routine to search the tree under the current symbol path for a file with this name and this index.
sup <i>Path File1 File2</i>	Stores a file in a symbol store, based on the values of the parameters. <i>Path</i> specifies the directory path of the symbol store. <i>File1</i> and <i>File2</i> are used to create a delta value, which is in turn used to determine the file being stored.

COMMAND	EFFECT
storeadd <i>File Store</i>	Adds the specified file to the specified symbol store. <i>Store</i> should be the root path of the symbol store.

The following table lists the DBH commands that apply to real and imaginary symbols.

COMMAND	EFFECT
undec <i>Name</i>	Reveals the meaning of the decorations attached to the specified symbol name. <i>Name</i> can be any string; it need not correspond to a currently loaded symbol. If <i>Name</i> contains C++ decorations, the meaning of these decorations is displayed.
add <i>Name Address Size</i>	Adds the specified imaginary symbol to the list of symbols loaded in DBH. <i>Name</i> specifies the name of the symbol to be added, <i>Address</i> specifies its hexadecimal address, and <i>Size</i> its hexadecimal size in bytes. This is treated like any other symbol in later DBH commands, until the DBH session is ended with quit or unload , or until the imaginary symbol is deleted with del . The actual target symbol file is not altered.
del <i>Name</i> del <i>Address</i>	Deletes an imaginary symbol previously added with the add command. The symbol can be specified either by name or by address. This cannot be used to delete real symbols.

PDBCopy

5/26/2017 • 1 min to read • [Edit Online](#)

The PDBCopy tool (pdbcOPY.exe) is a command-line tool that removes private symbol information from a symbol file. It can also remove selected information from the public symbol table.

This section includes:

[Using PDBCopy](#)

[Choosing Which Public Symbols to Remove](#)

[PDBCopy Command-Line Options](#)

[Send comments about this topic to Microsoft](#)

Using PDBCopy

5/31/2017 • 6 min to read • [Edit Online](#)

PDBCopy is a command-line tool that creates a stripped symbol file from a full symbol file. In other words, it takes a symbol file that contains both private symbol data and a public symbol table, and creates a copy of that file that contains only the public symbol table. Depending on which PDBCopy options are used, the stripped symbol file contains either the entire public symbol table or a specified subset of the public symbol table.

PDBCopy works with any PDB-format symbol file (with file name extension .pdb), but not with the older format (.dbg) symbol files.

For a description of public symbol tables and private symbol data, see [Public and Private Symbols](#).

Removing Private Symbols

If you wish to create a stripped symbol file that contains all the public symbols and none of the private symbols, use PDBCopy with three parameters: the path and name of the original symbol file, the path and name of the new symbol file, and the -p option.

For example, the following command creates a new file, named publicsymbols.pdb, which contains the same public symbol table as mysymbols.pdb but contains none of the private symbol data:

```
pdbcopy mysymbols.pdb publicsymbols.pdb -p
```

If mysymbols.pdb happens to already be a stripped symbol file, the symbolic content of the new file and the old file will be identical.

After issuing this command, you should move the new file to a new location and rename it to the original name of the symbol file (in this example, mysymbols.pdb), because most debugging programs and symbol extraction programs look for symbols based on a specific file name. Alternatively, you could use the same file name for the input file and the output file on the PDBCopy command line, as long as different directories are specified:

```
pdbcopy c:\dir1\mysymbols.pdb c:\dir2\mysymbols.pdb -p
```

Note The destination file should not exist before PDBCopy is run. If a file with this name exists, various errors may occur.

Removing Private Symbols and Selected Public Symbols

If you wish to not only remove the private symbol data, but also reduce the amount of information in the public symbol table, you can use the -f option to specify a list of public symbols that are to be removed.

The following example illustrates this procedure:

1. Determine the full names, including decorations, of the symbols you wish to remove. If you are not sure of the decorated symbol names, you can use the [DBH](#) tool to determine them. See [Determining the Decorations of a Specific Symbol](#) for details. In this example, let us suppose that the decorated names of the symbols you wish to remove are `_myGlobal1` and `_myGlobal2`.
2. Create a text file containing a list of the symbols to be removed. Each line in this file should include the name of one symbol, including decorations, but not including module names. In this example, the file would contain the following two lines:

```
_myGlobal1
_myGlobal2
```

The file can be given any name you choose. Let us suppose that you name this file listfile.txt and place it in the directory C:\Temp.

3. Use the following PDBCopy command line:

```
pdbscopy OldPDB NewPDB -p -f:@TextFile
```

where *OldPDB* and *NewPDB* are the original symbol file and the new symbol file, and *TextFile* is the file created in step two. The -f option indicates that certain public symbols are to be removed, and the ampersand (@) indicates that these symbols are listed in the specified text file.

In the current example, the command would look like this:

```
pdbscopy c:\dir1\mysymbols.pdb c:\dir3\mysymbols.pdb -p -f:@c:\temp\listfile.txt
```

This creates a new symbol file, C:\dir2\mysymbols.pdb, which does not contain any private symbols and does not contain the two global variables you listed in listfile.txt.

As shown in this example, PDBCopy's -f option removes a specific list of public symbols. The ampersand (@) indicates that these symbols are listed in a text file. An alternate method is to list all the symbols on the command line, using the -f option without an ampersand. Thus the following command line is equivalent to the example in the procedure above:

```
pdbscopy c:\dir1\mysymbols.pdb c:\dir3\mysymbols.pdb -p -f:_myGlobal1 -f:_myGlobal2
```

Unless you wish to remove only one or two symbols, it is simpler to use a text file than to list them on the command line.

If you wish to remove the majority of public symbols from your .pdb file, the -F option is the easiest method. While the -f option requires you to list those public symbols you wish to remove, the -F option requires you to list those public symbols you do not wish to remove. All other public symbols (as well as all private symbols) will be removed. The -F option supports the same two syntax options as the -f option: either -F: followed by the name of a symbol to be retained, or -F:@ followed by the name of a text file that contains a list of the symbols to be retained. In either case, decorated symbol names must be used.

For example, the following command removes all private symbols and almost all public symbols, leaving only the symbols **_myFunction5** and **_myGlobal7**:

```
pdbscopy c:\dir1\mysymbols.pdb c:\dir3\mysymbols.pdb -p -F:_myFunction5 -F:_myGlobal7
```

If you combine multiple instances of the -f option on one line, all the specified symbols are removed. If you combine multiple instances of the -F option on one line, all the specified symbols are retained, and all other symbols are removed. You cannot combine -f with -F.

The -f and -F options cannot be used without the -p option, which removes all private symbol data. Even if your original file contains no private symbols, you must still include the -p option (although it has no effect in this case).

The -F option cannot be used to prevent the private symbol data from being removed. If you use this option with a symbol that is not included in the public symbol table, PDBCopy ignores it.

The **mspdb*.dll** File

PDBCopy must access either the Mspdb80.dll file or the Mspdb60.dll file in order to run. By default, PDBCopy uses Mspdb80.dll, which is the version used by Visual Studio .NET 2002 and later versions of Visual Studio. If your symbols were built using Visual Studio 6.0 or an earlier version, you can specify the -vc6 command-line option so that PDBCopy uses Mspdb60.dll instead, although this is not required. PDBCopy looks for the appropriate file even if the -vc6 option is not used. You can find these files within your installation of Visual Studio, the Platform SDK, or

the Windows Driver Kit (WDK).

Before running PDBCopy, make sure that the correct version of mspdb*.dll file is accessible to your computer, and make sure that its location is part of the command path. If it is not, you should use the **path** command to add this location to the command path.

The File Signature and the SymSrv Index

Each symbol file has a fixed signature that uniquely identifies it. SymSrv uses the signature to generate a unique "index value" for the file. If two files have different contents or different creation times, they will also have distinct signatures and distinct SymSrv index values.

Files created with PDBCopy are an exception to the rule of unique index values. When PDBCopy creates a new symbol file, it has the same signature and SymSrv index value as the old file. This feature allows one file to be replaced with the other without altering the behavior of symbol-related tools.

If you wish the new file to have a distinct signature and SymSrv index, use the **-s** option. In most cases you will not wish to use this option, since the most common use of PDBCopy is to create an altered symbol file that can replace the old file without causing a mismatch. A new signature may cause SymSrv to assign a different index value to the new file than to the old file, preventing new file from properly replacing the old one.

For the complete command line syntax, see [PDBCopy Command-Line Options](#).

[Send comments about this topic to Microsoft](#)

Choosing Which Public Symbols to Remove

5/26/2017 • 3 min to read • [Edit Online](#)

PDBCopy supplies the -f and -F options so that you can remove an arbitrary set of public symbols from a stripped symbol file, leaving only those symbols that your audience needs to access in order to perform their debugging.

A common use of PDBCopy is to create a special version of your symbol file for use by Microsoft in its Online Crash Analysis (OCA) program. OCA can designate certain functions as *inert*, which means that if the function is found on the stack trace it is ignored. A function would typically be declared inert if it is simply a wrapper or "pass-through" function that performs no significant computations. If such a function is found on the stack in a failure analysis, it can be assumed that this function itself was not at fault, and at most it passed on invalid or corrupt data that it received from routines earlier on the stack. By ignoring such functions, OCA can better determine the actual cause of the error or corruption.

Naturally, any function that you wish to declare "inert" needs to be included in the public symbol table of the symbol file used by OCA. However, these are not the only functions that need to be included, as the following example shows.

Suppose that you write a Windows driver and you use PDBCopy to remove all public symbols from its symbol file, except for **FunctionOne** and **FunctionSix**, two inert functions. Your expectation is that if either **FunctionOne** or **FunctionSix** are found on the stack after a crash, they will be ignored by OCA. If any other part of your driver is on the stack, Microsoft will supply you with the corresponding memory address and you can use the address to debug your driver.

However, let us suppose that your driver occupies memory in the following layout:

ADDRESS	CONTENTS OF MEMORY
0x1000	Base address of the module
0x2000	Beginning of FunctionOne
0x203F	End of FunctionOne
0x3000	Beginning of FunctionSix
0x305F	End of FunctionSix
0x7FFF	End of the module in memory

If the debugger finds an address on the stack, it selects the symbol with the next lower address. Since the public symbol table contains the address of each symbol but no size information, there is no way for the debugger to know if an address actually falls within the boundaries of any specific symbol.

Therefore, if a fault occurs at address 0x2031, the debugger run by Microsoft OCA correctly identifies the fault as lying within **FunctionOne**. Since this is an inert function, the debugger continues walking the stack to find the cause of the crash.

However, if a fault occurs at 0x2052, the debugger still matches this address to **FunctionOne**, even though it lies beyond the actual end of this function (0x203F).

Consequently, you must include in your stripped symbol file not only the functions you wish to expose, but also the symbols immediately following these functions. In this example, you would wish to expose **FunctionOne**, **FunctionTwo**, **FunctionSix**, and **FunctionSeven**:

ADDRESS	CONTENTS OF MEMORY
0x1000	Base address of the module
0x2000	Beginning of FunctionOne
0x203F	End of FunctionOne
0x2040	Beginning of FunctionTwo
0x3000	Beginning of FunctionSix
0x305F	End of FunctionSix
0x3060	Beginning of FunctionSeven
0x7FFF	End of the module in memory

If you include all four of these functions in the stripped symbol file, then the Microsoft OCA analysis will not mistakenly treat the address 0x2052 as part of **FunctionOne**. In this example it will assume that this address is part of **FunctionTwo**, but that is not important because you have not registered **FunctionTwo** with OCA as an inert function. The important thing is that the address 0x2052 is recognized as not falling within an inert function, and therefore OCA will recognize this as a meaningful fault within your driver and can inform you of the fault.

If you do not wish to publicize the names of the functions following each inert function, you can insert unimportant functions into your code following each inert function so that the names of these functions can be included in your public symbol file. Be sure to verify that these added functions do indeed follow your inert functions in your binary's address space, since some optimization routines may alter this, or even remove some functions entirely.

PDBCopy Command-Line Options

5/31/2017 • 3 min to read • [Edit Online](#)

The PDBCopy command line uses the following syntax. The parameters can be included in any order.

```
pdccopy OldPDB NewPDB [Options]  
pdccopy OldPDB NewPDB -p [-f:Symbol] [-f:@TextFile] [Options]  
pdccopy OldPDB NewPDB -p [-F:Symbol] [-F:@TextFile] [Options]  
pdccopy /?
```

Parameters

OldPDB

Specifies the path and file name of the original symbol file to be read, including the .pdb file name extension.

OldPDB may contain the absolute or relative path of a directory on the local computer, or a UNC path. If no path is specified, the current working directory is used. If *OldPDB* contains spaces, it must be enclosed in quotation marks.

NewPDB

Specifies the path and file name of the new symbol file to be created, including the .pdb file name extension.

NewPDB may contain the absolute or relative path of a directory on the local computer, or a UNC path. This path must already exist; PDBCopy will not create a new directory. If no path is specified, the current working directory is used. If *NewPDB* contains spaces, you must enclose it in quotation marks. The specified file should not already exist; if it does, the new file may not be written, or may be written incorrectly.

-p

Causes PDBCopy to remove private symbol data from the new symbol file. If the old symbol file contains no private symbols, this option has no effect. If this option is omitted, PDBCopy creates a new file with identical symbol content as the original file.

-f:Symbol

Causes PDBCopy to remove the specified public symbol from the new symbol file. *Symbol* must specify the name of the symbol to be removed, including any symbol name decorations (for example, initial underscores), but not including the module name. This option requires the -p option. If you use multiple **-f** or **-f:@** parameters, PDBCopy removes all the specified symbols from the new symbol file.

-f:@TextFile

Causes PDBCopy to remove the public symbols listed in the specified text file from the new symbol file. *TextFile* specifies the file name and path (absolute or relative) of this file. This file can list the names of any number of symbols, one on each line, including any symbol name decorations (for example, initial underscores), but not including module names. This option requires the -p option.

-F:Symbol

Causes PDBCopy to remove all public and private symbols from the new symbol file, except for the specified public symbol. *Symbol* must specify the name of the symbol to be retained, including any symbol name decorations (for example, initial underscores), but not including the module name. This option requires the -p option. If multiple **-F** or **-F:@** parameters are used, all the specified symbols are retained in the new symbol file.

-F:@TextFile

Causes PDBCopy to remove all public and private symbols from the new symbol file, except for the public symbols

listed in the specified text file. *TextFile* specifies the file name and path (absolute or relative) of this file. This file can list the names of any number of symbols, one on each line, including any symbol name decorations (for example, initial underscores), but not including module names. This option requires the **-p** option.

Options

Any combination of the following options. These options are case-sensitive.

-s

Causes the new symbol file to have a different signature than the old file. Normally you should not use the **-s** option, because a new signature may cause SymSrv to assign a different index value to the new file than to the old file, preventing new file from properly replacing the old one.

-vc6

Causes PDBCopy to use mspdb60.dll instead of mspdb80.dll. This option is never required, because PDBCopy automatically looks for the proper version of mspdb*.dll. By default, PDBCopy uses mspdb80.dll, which is the version used by Visual Studio .NET 2002 and later versions of Visual Studio. If your symbols were built using Visual Studio 6.0 or an earlier version, you can specify this command-line option so that PDBCopy will use mspdb60.dll instead. However, this is not required, since PDBCopy looks for the appropriate file even if this option is not used. Whichever version of mspdb*.dll you use must be in the executable path of the Command Prompt window from which you launch PDBCopy.

-?

Displays help text for the PDBCopy command line.

Additional Information

For more information about the PDBCopy tool, see [Using PDBCopy](#).

SymChk

5/26/2017 • 1 min to read • [Edit Online](#)

SymChk (the Microsoft Symbol Checker tool), Symchk.exe, is a program that compares executable files to symbol files to verify that the correct symbols are available.

This section includes:

[Using SymChk](#)

[SymChk Command-Line Options](#)

[Send comments about this topic to Microsoft](#)

Using SymChk

5/31/2017 • 4 min to read • [Edit Online](#)

The basic syntax for SymChk is as follows:

```
symchk [/r] FileNames /s SymbolPath
```

FileNames specifies one or more program files whose symbols are needed. If *FileNames* is a directory and the **/r** flag is used, this directory is explored recursively, and SymChk will try to find symbols for all program files in this directory tree. *SymbolPath* specifies where SymChk is to search for symbols.

There are many more command-line options. For a full listing, see [SymChk Command-Line Options](#).

The symbol path specified can include any number of local directories, UNC directories, or symbol servers. Local directories and UNC directories are not searched recursively. Only the specified directory and a subdirectory based on the executable's extension are searched. For example, the query

```
symchk thisdriver.sys /s g:\symbols
```

will search g:\mysymbols and g:\mysymbols\sys.

You can specify a symbol server by using either of the following syntaxes as part of your symbol path:

```
srv*DownstreamStore*\\Server\\Share  
srv*\\Server\\Share
```

This is very similar to using a symbol server in the debugger's symbol path. For details on this, see [Using Symbol Servers and Symbol Stores](#).

If a downstream store is specified, SymChk will make copies of all valid symbol files found by the symbol server and place them in the downstream store. Only symbol files that are complete matches are copied downstream.

SymChk always searches the downstream store before querying the symbol server. Therefore you should be careful about using a downstream store when someone else is maintaining the symbol store. If you run SymChk once and it finds symbol files, it will copy those to the downstream store. If you then run SymChk again after these files have been altered or deleted on the symbol store, SymChk will not notice this fact, since it will find what it is looking for on the downstream store and look no further.

Note SymChk always uses SymSrv (SymSrv.dll) as its symbol server DLL. On the other hand, the debuggers can choose a symbol server DLL other than SymSrv if one is available. (SymSrv is the symbol server included in the Debugging Tools for Windows package.)

Using SymChk to determine whether symbols are private or public

To determine whether a symbol file is private or public, use the **/v** parameter so that SymChk displays verbose output. Suppose MyApp.exe and MyApp.pdb are in the folder c:\sym. Enter this command.

```
symchk /v c:\\sym\\MyApp.exe /s c:\\sym
```

If MyApp.pdb contains private symbols, the output of SymChk looks like this.

```
[SYMCHK] Searching for symbols to c:\sym\MyApp.exe in path c:\sym
...
DBGHELP: MyApp - private symbols & lines
c:\sym\MyApp.pdb
...
SYMCHK: FAILED files = 0
SYMCHK: PASSED + IGNORED files = 1
```

If MyApp.pdb contains only public symbols, the output of SymChk looks like this.

```
[SYMCHK] Searching for symbols to c:\sym\MyApp.exe in path c:\sym
...
DBGHELP: MyApp - public symbols
c:\sym\MyApp.pdb
...
SYMCHK: FAILED files = 0
SYMCHK: PASSED + IGNORED files = 1
```

To limit your search so that it finds only public symbol files, use the **s** option with the **/s** parameter (**/ss**). The following command finds a match if MyApp.pdb contains only public symbols. It does not find a match if MyApp.pdb contains private symbols.

symchk /v c:\sym\MyApp.exe /ss c:\sym

For more information, see [Public and Private Symbols](#).

Examples

Here are some examples. The following command searches for symbols for the program Myapp.exe:

```
e:\debuggers> symchk f:\myapp.exe /s f:\symbols\applications

SYMCHK: Myapp.exe          FAILED - Myapp.pdb is missing

SYMCHK: FAILED files = 1
SYMCHK: PASSED + IGNORED files = 0
```

You can try again with a different symbol path:

```
e:\debuggers> symchk f:\myapp.exe /s f:\symbols\newdirectory

SYMCHK: FAILED files = 0
SYMCHK: PASSED + IGNORED files = 1
```

The search was successful this time. If the verbose option is not used, SymChk will only list files for which it failed to find symbols. So in this example no files were listed. You can tell that the search succeeded because there is now one file listed in the "passed" category and none in the "failed" category.

A program file is ignored if it contains no executable code. Many resource files are of this type.

If you prefer to see the file names of all program files, you can use the **/v** option to generate verbose output:

```
e:\debuggers> symchk /v f:\myapp.exe /s f:\symbols\newdirectory

SYMCHK: MyApp.exe          PASSED

SYMCHK: FAILED files = 0
SYMCHK: PASSED + IGNORED files = 1
```

The following command searches for a huge number of Windows symbols in a symbol server. There are a great variety of possible error messages:

```
e:\debuggers> symchk /r c:\windows\system32 /s srv*\manysymbols\windows

SYMCHK: msisam11.dll          FAILED - MSISAM11.pdb is missing
SYMCHK: msuni11.dll          FAILED - msuni11link.pdb is missing
SYMCHK: msdxm.ocx          FAILED - Image is split correctly, but msdxm.dbg is
s missing
SYMCHK: expsrv.dll          FAILED - Checksum doesn't match with expsrv.DBG
SYMCHK: imeshare.dll          FAILED - imeshare.opt.pdb is missing
SYMCHK: ir32_32.dll          FAILED - Built with no debugging information
SYMCHK: author.dll          FAILED - rpctest.pdb is missing
SYMCHK: msvcrt40.dll          FAILED - Built with no debugging information
.....
SYMCHK: FAILED files = 211
SYMCHK: PASSED + IGNORED files = 4809
```

Using a Manifest File with SymChk

5/26/2017 • 1 min to read • [Edit Online](#)

In some cases, you might need to retrieve symbols for files that are on an isolated computer; that is, a computer that is either not on any network or is on a network that has no symbol store. In that situation, you can use the following procedure to retrieve symbols.

1. Run SymChk with the **/om** parameter to create a manifest file that describes the files for which you want to retrieve symbols.
2. Move the manifest file to a network that has a symbol store.
3. Run SymChk with **/im** parameter to retrieve symbols for the files described in the manifest file.
4. Move the symbol files back to the isolated computer.

Example

Suppose yourApp.exe is running on an isolated computer. The following command creates a manifest file that describes all the symbols needed to debug the yourApp.exe process.

```
C:\>SymChk /om c:\Manifest\man.txt /ie yourApp.exe

SYMCHK: FAILED files = 0
SYMCHK: PASSED + IGNORED files = 28
```

Now assume you have moved the manifest file to a different computer that is on a network that has access to a symbol store. The following command retrieves the symbols described in the manifest file and places them in the mySymbols folder.

```
C:\>SymChk /im c:\FolderOnOtherComputer\man.txt /s srv*c:\mysymbols*\aServer\symbols

SYMCHK: myApp.exe           ERROR - Unable to download file. Error reported was 2
. . .
SYMCHK: FAILED files = 28
SYMCHK: PASSED + IGNORED files = 28
```

Now you can move the symbols to the isolated computer and use them for debugging.

[Send comments about this topic to Microsoft](#)

SymChk Command-Line Options

5/31/2017 • 7 min to read • [Edit Online](#)

SymChk uses the following syntax:

```
symchk [/r] [/v | /q] FileNames /s[Opts] SymbolPath Options
symchk [/r] [/v | /q] /ie ExeFile /s[Opts] SymbolPath Options
symchk [/r] [/v | /q] /id DumpFile /s[Opts] SymbolPath Options
symchk [/r] [/v | /q] /ih HotFixFile /s[Opts] SymbolPath Options
symchk [/r] [/v | /q] /ip ProcessID /s[Opts] SymbolPath Options
symchk [/r] [/v | /q] /it TextFileList /s[Opts] SymbolPath Options
symchk [/r] [/v | /q] /om Manifest FileNames
symchk [/v | /q] /im ManifestList /s[Opts] SymbolPath Options
symchk [/v | /q] /om Manifest /ie ExeFile
symchk [/v | /q] /om Manifest /id DumpFile
symchk [/v | /q] /om Manifest /ih HotFixFile
symchk [/v | /q] /om Manifest /ip ProcessFile
symchk [/v | /q] /om Manifest /it TextFileList
```

Parameters

/r

If *Files* specifies a directory, the **/r** option causes SymChk to recursively search all subdirectories under this directory for program files.

/v

Displays verbose information. This includes the file name of every program file whose symbols were investigated and whether it passed, failed, or was ignored.

/q

Enables quiet mode. All output will be suppressed (unless the **/ot** option is included).

FileNames

Specifies the program files whose symbols are to be checked. Absolute paths, relative paths, and UNC paths are permitted. An asterisk (`\wildcard` is permitted. If `*FileNames` ends in a slash, it is taken to be a directory name, and all files within that directory are checked. If *FileNames* contains spaces, it must be enclosed in quotation marks.

/ie ExeFile

Specifies the name of a program that is currently executing. The symbols for this program will be checked. *ExeFile* must include the name of the file and file extension (usually `.exe`), but no path information. If there are two different executables with the same name, this option is not recommended. *ExeFile* can specify any program, including a kernel-mode driver. If *ExeFile* is a single asterisk (`*`), SymChk will check the symbols for all running processes, including drivers.

/id *DumpFile*

Specifies a memory dump file. The symbols for this dump file will be checked.

/ih *HotFixFile*

Specifies a self-extracting Hotfix CAB file.

/ip *ProcessID*

Specifies the process ID of a program that is currently executing. The symbols for this program will be checked.

ProcessID must be specified as a decimal number. There are two special wildcards supported:

- If *ProcessID* is zero (**0**), SymChk will check the symbols for all running drivers.
- If *ProcessID* is a single asterisk (*****), SymChk will check the symbols for all running processes, including drivers.

/it *TextFileList*

Specifies a text file that contains a list of program files. The symbols for all these programs will be checked.

TextFileList must specify exactly one file (by relative, absolute, or UNC path, but with no wildcards); if it contains spaces it should be enclosed in quotation marks. Within this file, each line indicates a program file (by relative, absolute, or UNC paths), and an asterisk wildcard (*****) is permitted. However, any line using this wildcard must use a relative path.

If a line in this file contains spaces, it should be enclosed in quotation marks. A semicolon within this file is a comment character -- everything between a semicolon and the end of the line will be ignored.

/im *ManifestList*

Specifies that the input to the command is a manifest file previously created by using the **/om** parameter. The manifest file contains information about the files for which symbols are retrieved. For more information about using a manifest file, see [Using a Manifest File with SymChk](#).

/om *Manifest*

Specifies that a manifest file is created. The manifest file contains information about a set of files for which symbols will be retrieved, by using the **/im** parameter, at a later time.

/s[Opts] *SymbolPath*

Specifies the directories containing symbols. Absolute paths, relative paths, and UNC paths are permitted. Any number of directories can be specified -- multiple directories should be separated with semicolons. If *SymbolPath* contains spaces, it must be enclosed in quotation marks. If you wish to specify a symbol server within this path, you should use one of the following syntaxes:

```
srv*DownstreamStore*\\Server\\Share
srv*\\Server\\Share
```

It is not recommended that you omit the **/s[Opts]** *SymbolPath* parameter, but if it is omitted, SymChk will point to the public symbol store by using the following default path:

```
srv%%SystemRoot%\\symbols*https://msdl.microsoft.com/download/symbols
```

Any number of the following options can follow **/s**. There can be no space between the **/s** and these options:

e

SymChk will check each path individually instead of checking all paths at once.

u

Downstream stores will be updated. If the symbol path includes a downstream store, the symbol store will be searched for the symbol files. Only symbol stores that are being checked by SymChk will be updated.

p

Force checking for private symbols. Public symbols will be treated as not matching. The **p** option implies **e** and **u**, and cannot be used with **s**.

s

Force checking for public (split) symbols. Private symbols will be treated as not matching. The **s** option implies **e** and **u**, and cannot be used with **p**.

Options

The available options are divided into several classes. Each class of options controls a different set of features.

Output options. Any number of the following options can be specified. These options can be abbreviated by using **/o** only once -- for example, **/oi /oe** can be written as **/oie**.

OPTION	EFFECT
/oe	Output will include individual errors. This option is only useful if /q is used, because individual errors are automatically displayed if quiet mode hasn't been activated.
/op	Output will list each file that passes. (By default, SymChk only displays files that fail testing.)
/oi	Output will list each file that was ignored. (By default, SymChk only displays files that fail testing.)
/od	Output will include full details. Same as /oe /op /oi .
/ot	Output will include result totals. This option is only useful if /q is used, because these totals are automatically displayed if quiet mode hasn't been activated.
/ob	The full path for binaries will be included in all output messages.
/os	The full path for symbols will be included in all output messages.
/oc <i>Dir</i>	SymChk will create a traditional symbol tree in the directory <i>Dir</i> that contains a list of all the symbol files checked.

DBG file options. These options control how SymChk checks *.dbg* symbol files. Only one of the following options can be specified.

OPTION	EFFECT

OPTION	EFFECT
/ds	SymChk will verify that .dbg information was stripped from the executable and only appears in the .dbg file, and that the executable points to the .dbg file. If the program was built without .dbg symbol files, this option has no effect. This is the default.
/de	SymChk will verify that .dbg information was not stripped from the executable and that the executable does not point to a .dbg file. If the program was built without .dbg symbol files, this option has no effect.
/dn	SymChk will verify that .dbg information is not present in the image, and that the image does not point to a .dbg file.

PDB file options. These options control how SymChk checks .pdb symbol files. Only one of the following options can be specified.

OPTION	EFFECT
/pf	SymChk performs no checking on the contents of the .pdb file -- it just verifies that the files exist and match the binary. This is the default.
/ps	SymChk will verify that the .pdb files have been stripped of source line, data type, and global information.
/pt	SymChk will verify that the .pdb files contain data type information.

Filtering options. These options control how module filtering is performed when SymChk is checking processes or dump files. Only one of the following options can be specified.

OPTION	EFFECT
/fm <i>Module</i>	SymChk will only check dump files or processes associated with the specified module. <i>Module</i> must include the full filename, but must not include any part of the directory path.

Symbol checking options. Any number of the following options can be specified.

OPTION	EFFECT
/cs	SymChk won't verify that CodeView data is present. (By default, the presence of CodeView data is verified.)

OPTION	EFFECT
/cc	When SymChk is checking a hotfix CAB file, it will not look for symbols inside the cab. (By default, SymChk will look for symbols in the cab as well as in the provided symbol path.)
/ea <i>File</i>	SymChk won't verify symbols for the programs listed in the specified file. This allows you to veto certain programs that would otherwise be verified. <i>File</i> must specify exactly one file (by relative, absolute, or UNC path, but without wildcards); if it contains spaces it should be enclosed in quotation marks. Within <i>File</i> , each line indicates a program file (by relative, absolute, or UNC paths); no wildcards are permitted. If a line in this file contains spaces it should be enclosed in quotation marks. A semicolon within this file is a comment character -- everything between a semicolon and the end of the line will be ignored. If a symbol server is being used, symbols for these programs will not be copied to the downstream store.
/ee <i>File</i>	Error messages for those programs listed in the specified file are suppressed. "Success" and "ignore" messages will appear as usual, and symbol files will be copied to the downstream store as usual. The format of <i>File</i> and the format of its contents are the same as that for /ea <i>File</i> .

Additional Information

For more information about SymChk, see [Using SymChk](#).

Crash dump analysis using the Windows debuggers (WinDbg)

5/31/2017 • 1 min to read • [Edit Online](#)

You analyze crash dump files by using WinDbg and other Windows debuggers.

This section includes:

[Kernel-Mode Dump Files](#)

[User-Mode Dump Files](#)

[Extracting Information from a Dump File](#) **Note** This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

[Send comments about this topic to Microsoft](#)

Kernel-Mode Dump Files

5/26/2017 • 1 min to read • [Edit Online](#)

When a kernel-mode error occurs, the default behavior of Microsoft Windows is to display the blue screen with bug check data.

However, there are several alternative behaviors that can be selected:

- A kernel debugger (such as WinDbg or KD) can be contacted.
- A memory dump file can be written.
- The system can automatically reboot.
- A memory dump file can be written, and the system can automatically reboot afterwards.

This section covers how to create and analyze a kernel-mode memory dump file. There are three different varieties of crash dump files. However, it should be remembered that no dump file can ever be as useful and versatile as a live kernel debugger attached to the system that has failed.

This section includes:

[Varieties of Kernel-Mode Dump Files](#)

[Creating a Kernel-Mode Dump File](#)

[Analyzing a Kernel-Mode Dump File](#)

[Send comments about this topic to Microsoft](#)

Varieties of Kernel-Mode Dump Files

6/9/2017 • 1 min to read • [Edit Online](#)

There are five settings for kernel-mode crash dump files:

[Complete Memory Dump](#)

[Kernel Memory Dump](#)

[Small Memory Dump](#)

[Automatic Memory Dump](#)

[Active Memory Dump](#)

The difference between these dump files is one of size. The *Complete Memory Dump* is the largest and contains the most information, including some User-Mode memory. The *Active Memory Dump* is somewhat smaller but contains similar information for most purposes. The *Kernel Memory Dump* is smaller still and typically omits User-Mode memory, and the *Small Memory Dump* is only 64 KB in size.

If you select *Automatic Memory Dump*, the dump file is the same as a *Kernel Memory Dump*, but Windows has more flexibility in setting the size of the system paging file.

The advantage to the larger files is that, since they contain more information, they are more likely to help you find the cause of the crash.

The advantage of the smaller files is that they are smaller and written more quickly. Speed is often valuable; if you are running a server, you may want the server to reboot as quickly as possible after a crash, and the reboot will not take place until the dump file has been written.

After a *Complete Memory Dump* or *Kernel Memory Dump* has been created, it is possible to create a *Small Memory Dump* file from the larger dump file. See the [.dump \(Create Dump File\)](#) command for details.

Note Much information can be obtained by analyzing a kernel-mode dump file. However, no kernel-mode dump file can provide as much information as actually debugging the crash directly with a kernel debugger.

[Kernel-Mode Dump Files](#)

[Enabling a Kernel-Mode Dump File](#)

[Send comments about this topic to Microsoft](#)

Complete Memory Dump

5/26/2017 • 1 min to read • [Edit Online](#)

A *Complete Memory Dump* is the largest kernel-mode dump file. This file includes all of the physical memory that is used by Windows. A complete memory dump does not, by default, include physical memory that is used by the platform firmware.

Starting with Windows 8, you can register a *BugCheckAddPagesCallback* routine that is called during a complete memory dump. Your *BugCheckAddPagesCallback* routine can specify driver-specific data to add to the dump file. For example, this additional data can include physical pages that are not mapped to the system address range in virtual memory but that contain information that can help you to debug your driver. The *BugCheckAddPagesCallback* routine might add to the dump file any driver-owned physical pages that are unmapped or that are mapped to user-mode addresses in virtual memory.

This dump file requires a pagefile on your boot drive that is at least as large as your main system memory; it should be able to hold a file whose size equals your entire RAM plus one megabyte.

The Complete Memory Dump file is written to %SystemRoot%\Memory.dmp by default.

If a second bug check occurs and another Complete Memory Dump (or Kernel Memory Dump) is created, the previous file will be overwritten.

[Varieties of Kernel-Mode Dump Files](#)

[Send comments about this topic to Microsoft](#)

Kernel Memory Dump

5/26/2017 • 1 min to read • [Edit Online](#)

A *Kernel Memory Dump* contains all the memory in use by the kernel at the time of the crash.

This kind of dump file is significantly smaller than the Complete Memory Dump. Typically, the dump file will be around one-third the size of the physical memory on the system. This quantity will vary considerably, depending on your circumstances.

This dump file will not include unallocated memory, or any memory allocated to user-mode applications. It only includes memory allocated to the Windows kernel and hardware abstraction level (HAL), as well as memory allocated to kernel-mode drivers and other kernel-mode programs.

For most purposes, this crash dump is the most useful. It is significantly smaller than the Complete Memory Dump, but it only omits those portions of memory that are unlikely to have been involved in the crash.

Since this kind of dump file does not contain images of any user-mode executables residing in memory at the time of the crash, you may also need to set the executable image path if these executables turn out to be important.

The Kernel Memory Dump file is written to %SystemRoot%\Memory.dmp by default.

If a second bug check occurs and another Kernel Memory Dump (or Complete Memory Dump) is created, the previous file will be overwritten.

To suppress missing page error messages when debugging a Kernel Memory Dump, use the [.ignore_missing_pages](#) command.

Related topics

[Varieties of Kernel-Mode Dump Files](#)

[Send comments about this topic to Microsoft](#)

Small Memory Dump

5/26/2017 • 1 min to read • [Edit Online](#)

A *Small Memory Dump* is much smaller than the other two kinds of kernel-mode crash dump files. It is exactly 64 KB in size, and requires only 64 KB of pagefile space on the boot drive.

This dump file includes the following:

- The bug check message and parameters, as well as other blue-screen data.
- The processor context (PRCB) for the processor that crashed.
- The process information and kernel context (EPROCESS) for the process that crashed.
- The thread information and kernel context (ETHREAD) for the thread that crashed.
- The kernel-mode call stack for the thread that crashed. If this is longer than 16 KB, only the topmost 16 KB will be included.
- A list of loaded drivers.

In Windows XP and later versions of Windows, the following items are also included:

- A list of loaded modules and unloaded modules.
- The debugger data block. This contains basic debugging information about the system.
- Any additional memory pages that Windows identifies as being useful in debugging failures. This includes the data pages that the registers were pointing to when the crash occurred, and other pages specifically requested by the faulting component.
- (Windows Server 2003 and later) The Windows SKU -- for example, "Professional" or "Server".

This kind of dump file can be useful when space is greatly limited. However, due to the limited amount of information included, errors that were not directly caused by the thread executing at time of crash may not be discovered by an analysis of this file.

Since this kind of dump file does not contain images of any executables residing in memory at the time of the crash, you may also need to set the executable image path if these executables turn out to be important.

If a second bug check occurs and a second Small Memory Dump file is created, the previous file will be preserved. Each additional file will be given a distinct name, which contains the date of the crash encoded in the filename. For example, mini022900-01.dmp is the first memory dump file generated on February 29, 2000. A list of all Small Memory Dump files is kept in the directory %SystemRoot%\Minidump.

[Varieties of Kernel-Mode Dump Files](#)

[Send comments about this topic to Microsoft](#)

Automatic Memory Dump

5/26/2017 • 1 min to read • [Edit Online](#)

An **Automatic Memory Dump** contains the same information as a [Kernel Memory Dump](#). The difference between the two is not in the dump file itself, but in the way that Windows sets the size of the system paging file.

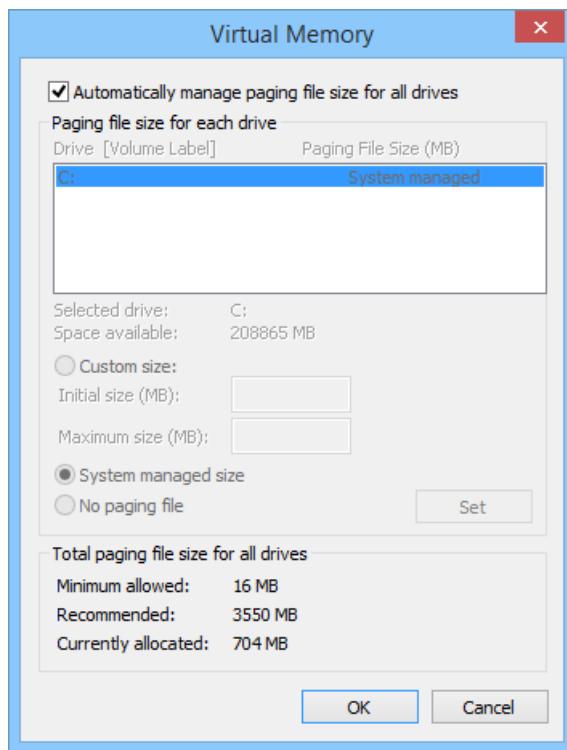

If the system paging file size is set to **System managed size**, and the kernel-mode crash dump is set to **Automatic Memory Dump**, then Windows can set the size of the paging file to less than the size of RAM. In this case, Windows sets the size of the paging file large enough to ensure that a kernel memory dump can be captured most of the time.

If the computer crashes and the paging file is not large enough to capture a kernel memory dump, Windows increases the size of the paging file to at least the size of RAM. The time of this event is recorded here in the Registry:

HKLM\SYSTEM\CurrentControlSet\Control\CrashControl\LastCrashTime

The increased paging file size stays in place for 4 weeks and then returns to the smaller size. If you want to return to the smaller paging file before 4 weeks, you can delete the Registry entry.

To see the paging file settings, go to **Control Panel > System and Security > System > Advanced system settings**. Under **Performance**, click **Settings**. On the **Advanced** tab, under **Virtual memory**, click **Change**. In the Virtual Memory dialog box, you can see the paging file settings.

The Automatic Memory Dump file is written to `%SystemRoot%\Memory.dmp` by default.

The Automatic Memory Dump is available in Windows 8 and later.

Note To suppress missing page error messages when debugging an Automatic Memory Dump, use the [.ignore_missing_pages](#) command.

Related topics

Varieties of Kernel-Mode Dump Files

[Send comments about this topic to Microsoft](#)

Active Memory Dump

6/9/2017 • 1 min to read • [Edit Online](#)

An *Active Memory Dump* is similar to a [Complete Memory Dump](#), but it filters out pages that are not likely to be relevant to troubleshooting problems on the host machine. Because of this filtering, it is typically significantly smaller than a complete memory dump.

This dump file does include any memory allocated to user-mode applications. It also includes memory allocated to the Windows kernel and hardware abstraction level (HAL), as well as memory allocated to kernel-mode drivers and other kernel-mode programs. The dump includes active pages mapped into the kernel or user space that are useful for debugging, as well as selected Pagefile-backed Transition, Standby, and Modified pages such as the memory allocated with VirtualAlloc or page-file backed sections. Active dumps do not include pages on the free and zeroed lists, the file cache, guest VM pages and various other types of memory that are not likely to be useful during debugging.

An Active Memory Dump is particularly useful when Windows is hosting virtual machines (VMs). When taking a complete memory dump, the contents of each VM is included. When there are multiple VMs running, this can account for a large amount of memory in use on the host system. Many times, the code activities of interest are in the parent host OS, not the child VMs. An active memory dump filters out the memory associated with all of the child VMs.

The Active Memory Dump file is written to %SystemRoot%\Memory.dmp by default.

The Active Memory Dump is available in Windows 10 and later.

Note To suppress missing page error messages when debugging an Active Memory Dump, use the [.ignore_missing_pages](#) command.

Creating a Kernel-Mode Dump File

5/26/2017 • 1 min to read • [Edit Online](#)

There are three ways in which a kernel-mode dump file can be created:

1. You can enable the dump file from the Control Panel, and then the system can crash on its own.
2. You can enable the dump file from the Control Panel, and then force the system to crash.
3. You can use the debugger to create a dump file without crashing the system.

This section includes:

[Enabling a Kernel-Mode Dump File](#)

[Forcing a System Crash](#)

[Creating a Dump File Without a System Crash](#)

[Verifying the Creation of a Kernel-Mode Dump File](#)

Using an NMI Switch

It is also possible to use an NMI switch to create a crash dump file. Contact your hardware vendor to determine whether your machine has this switch.

The usage of NMI switches is not covered in this documentation.

[Send comments about this topic to Microsoft](#)

Enabling a Kernel-Mode Dump File

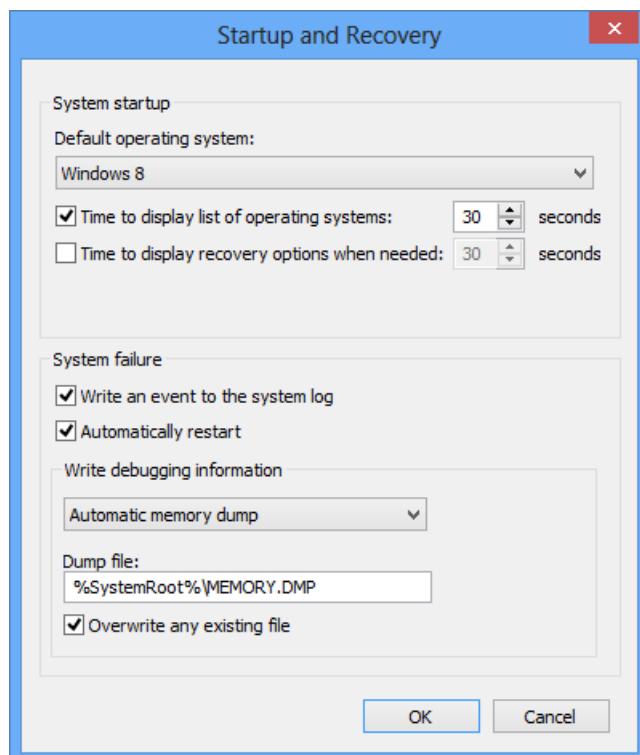

5/26/2017 • 1 min to read • [Edit Online](#)

During a system crash, the Windows crash dump settings determine whether a dump file will be created, and if so, what size the dump file will be.

The Windows Control Panel controls the kernel-mode crash dump settings. Only a system administrator can modify these settings.

To change these settings, go to **Control Panel > System and Security > System**. Click **Advanced system settings**. Under **Startup and Recovery**, click **Settings**.

You will see the following dialog box:

Under **Write Debugging Information**, you can specify a kernel-mode dump file setting. Only one dump file can be created for any given crash. See [Varieties of Kernel-Mode Dump Files](#) for a description of different dump file settings.

You can also select or deselect the **Write an event to the system log** and **Automatically restart** options.

The settings that you select will apply to any kernel-mode dump file created by a system crash, regardless of whether the system crash was accidental or whether it was caused by the debugger. See [Forcing a System Crash](#) for details on causing a deliberate crash.

However, these settings do not affect dump files created by the **.dump** command. See [Creating a Dump File Without a System Crash](#) for details on using this command.

[Send comments about this topic to Microsoft](#)

Forcing a System Crash

5/26/2017 • 1 min to read • [Edit Online](#)

Once kernel-mode dump files have been [enabled](#), most system crashes should cause a crash file to be written and the blue screen to be displayed.

However, there are times that a system freezes without actually initiating a kernel crash. Possible symptoms of such a freeze include:

- The mouse pointer moves, but can't do anything.
- All video is frozen, the mouse pointer does not move, but paging continues.
- There is no response at all to the mouse or keyboard, and no use of the disk.

If an experienced debugging technician is present, he or she can hook up a kernel debugger and analyze the problem. For some tips on what to look for when this situation occurs, see [Debugging a Stalled System](#).

However, if no technician is present, you may wish to create a kernel-mode dump file and send it to an off-site technician. This dump file can be used to analyze the cause of the error.

There are two ways to deliberately cause a system crash:

[Forcing a System Crash from the Debugger](#)

[Forcing a System Crash from the Keyboard](#)

[Send comments about this topic to Microsoft](#)

Forcing a System Crash from the Debugger

5/26/2017 • 1 min to read • [Edit Online](#)

If KD or WinDbg is performing kernel-mode debugging, it can force a system crash to occur. This is done by entering the **.crash (Force System Crash)** command at the command prompt. (If the target computer does not crash immediately, follow this with the **g (Go)** command.)

When this command is issued, the system will call **KeBugCheck** and issue **bug check 0xE2 (MANUALLY_INITIATED_CRASH)**. Unless crash dumps have been disabled, a crash dump file is written at this point.

After the crash dump file has been written, the kernel debugger on the host computer will be alerted and can be used to actively debug the crashed target.

[Send comments about this topic to Microsoft](#)

Forcing a System Crash from the Keyboard

5/26/2017 • 3 min to read • [Edit Online](#)

Most of the following keyboards can cause a system crash directly:

PS/2 keyboards connected on i8042prt ports

This feature is available in Windows 2000 and later versions of Windows operating system.

USB keyboards

This feature is available in:

- Windows Server 2003 Service Pack 1 if the hotfix available with [KB 244139](#) is installed.
- Windows Server 2003 (with Service Pack 2 or later).
- Windows Vista Service Pack 1 if the hotfix available with [KB 971284](#) is installed.
- Windows Vista Service Pack 2.
- Windows Server 2008 Service Pack 1 if the hotfix available with [KB 971284](#) is installed.
- Windows Server 2008 (with Service Pack 2 or later).
- Windows 7 and later versions of Windows operating system.

Note This feature is not available in Windows XP.

You must ensure the following three settings before the keyboard can cause a system crash:

1. If you wish a crash dump file to be written, you must enable such dump files, choose the path and file name, and select the size of the dump file. For more information, see [Enabling a Kernel-Mode Dump File](#).
2. With PS/2 keyboards, you must enable the keyboard-initiated crash in the registry. In the registry key **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\i8042prt\Parameters**, create a value named **CrashOnCtrlScroll**, and set it equal to a REG_DWORD value of 0x01.
3. With USB keyboards, you must enable the keyboard-initiated crash in the registry. In the registry key **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\kbdhid\Parameters**, create a value named **CrashOnCtrlScroll**, and set it equal to a REG_DWORD value of 0x01.

You must restart the system for these settings to take effect.

After this is completed, the keyboard crash can be initiated by using the following hotkey sequence: Hold down the rightmost CTRL key, and press the SCROLL LOCK key twice.

The system then calls **KeBugCheck** and issues **bug check 0xE2** (MANUALLY_INITIATED_CRASH). Unless crash dumps have been disabled, a crash dump file is written at this point.

If a kernel debugger is attached to the crashed machine, the machine will break into the kernel debugger after the crash dump file has been written.

For more information on using this feature, refer to the article [Generate a memory dump file by using the keyboard \(KB 244139\)](#).

Defining Alternate Keyboard Shortcuts to Force a System Crash from the Keyboard

You can configure values under the following registry subkeys for different keyboard shortcut sequences to generate the memory dump file:

- For PS/2 keyboards:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\i8042prt\crashdump

- For USB keyboards:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\kbdhid\crashdump

You must create the following registry REG_DWORD values under these subkeys:

Dump1Keys

The **Dump1Keys** registry value is a bit map of the first hot key to use. For example, instead of using the rightmost CTRL key to initiate the hot key sequence, you can set the first hot key to be the leftmost SHIFT key.

The values for the first hot key are described in the following table.

VALUE	FIRST KEY USED IN THE KEYBOARD SHORTCUT SEQUENCE
0x01	Rightmost SHIFT key
0x02	Rightmost CTRL key
0x04	Rightmost ALT key
0x10	Leftmost SHIFT key
0x20	Leftmost CTRL key
0x40	Leftmost ALT key

Note You can assign **Dump1Keys** a value that enables one or more keys as the first key used in the keyboard shortcut sequence. For example, assign **Dump1Keys** a value of 0x11 to define both the rightmost and leftmost SHIFT keys as the first key in the keyboard shortcut sequence.

Dump2Key

The **Dump2Key** registry value is the index into the scancode table for the keyboard layout of the target computer. The following is the actual table in the driver.

```
const UCHAR keyToScanTbl[134] = {
    0x00, 0x29, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x08, 0x09,
    0x0A, 0x0B, 0x0C, 0x0D, 0x7D, 0x0E, 0x0F, 0x10, 0x11, 0x12,
    0x13, 0x14, 0x15, 0x16, 0x17, 0x18, 0x19, 0x1A, 0x1B, 0x00,
    0x3A, 0x1E, 0x1F, 0x20, 0x21, 0x22, 0x23, 0x24, 0x25, 0x26,
    0x27, 0x28, 0x2B, 0x1C, 0x2A, 0x00, 0x2C, 0x2D, 0x2E, 0x2F,
    0x30, 0x31, 0x32, 0x33, 0x34, 0x35, 0x73, 0x36, 0x1D, 0x00,
    0x38, 0x39, 0xB8, 0x00, 0x9D, 0x00, 0x00, 0x00, 0x00, 0x00,
    0x00, 0x00, 0x00, 0x00, 0x00, 0xD2, 0xD3, 0x00, 0x00, 0xCB,
    0xC7, 0xCF, 0x00, 0xC8, 0xD0, 0xC9, 0xD1, 0x00, 0x00, 0xCD,
    0x45, 0x47, 0x4B, 0x4F, 0x00, 0x85, 0x48, 0x4C, 0x50, 0x52,
    0x37, 0x49, 0x4D, 0x51, 0x53, 0x4A, 0x4E, 0x00, 0x9C, 0x00,
    0x01, 0x00, 0x3B, 0x3C, 0x3D, 0x3E, 0x3F, 0x40, 0x41, 0x42,
    0x43, 0x44, 0x57, 0x58, 0x00, 0x46, 0x00, 0x00, 0x00, 0x00,
    0x00, 0x7B, 0x79, 0x70 };

```

Note Index 124 (sysreq) is a special case because an 84-key keyboard has a different scan code.

If you define alternate keyboard shortcuts to force a system crash from a USB or PS/2 keyboard, you must either set the **CrashOnCtrlScroll** registry value to 0 or remove it from the registry.

Limitations

It is possible for a system to freeze in such a way that the keyboard shortcut sequence will not work. However, this should be a very rare occurrence. Using the keyboard shortcut sequence to initiate a crash will work even in many instances where CTRL+ALT+DELETE does not work.

Forcing a system crash from the keyboard does not work if the computer stops responding at a high interrupt request level (IRQL). This limitation exists because the Kbdhid.sys driver, which allows the memory dump process to run, operates at a lower IRQL than the i8042prt.sys driver.

Creating a Dump File Without a System Crash

5/26/2017 • 1 min to read • [Edit Online](#)

If KD or WinDbg is performing kernel-mode debugging, it can cause a kernel-mode dump file to be written without crashing the target computer.

This dump file can be either a Complete Memory Dump or a Small Memory Dump. The Control Panel settings are not relevant to this action.

Whereas dump files caused by a system crash are written to the computer that has crashed, this dump file will be written to the host computer.

For details, see the [.dump \(Create Dump File\)](#) command.

[Send comments about this topic to Microsoft](#)

Verifying the Creation of a Kernel-Mode Dump File

5/26/2017 • 1 min to read • [Edit Online](#)

If you have a machine that has broken into the debugger, but you are unsure whether the crash dump file was successfully written, execute the following command:

```
dd nt!IopFinalCrashDumpStatus L1
```

This displays the value of the **IopFinalCrashDumpStatus** variable.

If this value equals zero, the process was successful. If it equals -1 (0xFFFFFFFF), the dump process has not started.

Any other value is a status code indicating an error during the dump process.

Analyzing a Kernel-Mode Dump File

5/26/2017 • 1 min to read • [Edit Online](#)

This section includes:

[Analyzing a Kernel-Mode Dump File with KD](#)

[Analyzing a Kernel-Mode Dump File with WinDbg](#)

[Analyzing a Kernel-Mode Dump File with KAnalyze](#)

Installing Symbol Files

Regardless of which tool you use, you need to install the symbol files for the version of Windows that generated the dump file. These files will be used by the debugger you choose to use to analyze the dump file. For more information about the proper installation of symbol files, see [Installing Windows Symbol Files](#).

DumpExam

The DumpExam tool is obsolete. It is no longer needed in the analysis of a crash dump file.

[Send comments about this topic to Microsoft](#)

Analyzing a Kernel-Mode Dump File with KD

5/26/2017 • 2 min to read • [Edit Online](#)

Kernel-mode memory dump files can be analyzed by KD. The processor or Windows version that the dump file was created on does not need to match the platform on which KD is being run.

Starting KD

To analyze a dump file, start KD with the **-z** command-line option:

```
kd -y SymbolPath -i ImagePath -z DumpFileName
```

The **-v** option (verbose mode) is also useful. For a full list of options, see [KD Command-Line Options](#).

You can also open a dump file after the debugger is running by using the [.opendump \(Open Dump File\)](#) command, followed with [g \(Go\)](#).

It is possible to debug multiple dump files at the same time. This can be done by including multiple **-z** switches on the command line (each followed by a different file name), or by using [.opendump](#) to add additional dump files as debugger targets. For information about how to control a multiple-target session, see [Debugging Multiple Targets](#).

Dump files generally end with the extension .dmp or .mdmp. You can use network shares or Universal Naming Convention (UNC) file names for the memory dump file.

It is also common for dump files to be packed into a CAB file. If you specify the file name (including the .cab extension) after the **-z** option or as the argument to an [.opendump](#) command, the debugger can read the dump files directly out of the CAB. However, if there are multiple dump files stored in a single CAB, the debugger will only be able to read one of them. The debugger will not read any additional files from the CAB, even if they were symbol files or other files associated with the dump file.

Analyzing the Dump File

If you are analyzing a Kernel Memory Dump or a Small Memory Dump, you may need to set the executable image path to point to any executable files which may have been loaded in memory at the time of the crash.

Analysis of a dump file is similar to analysis of a live debugging session. See the [Debugger Commands](#) reference section for details on which commands are available for debugging dump files in kernel mode.

In most cases, you should begin by using [!analyze](#). This extension command performs automatic analysis of the dump file and can often result in a lot of useful information.

The [.bugcheck \(Display Bug Check Data\)](#) shows the bug check code and its parameters. Look up this bug check in the [Bug Check Code Reference](#) for information about the specific error.

The following debugger extensions are especially useful for analyzing a kernel-mode crash dump:

!drivers

!kdext*.locks

!memusage

!vm

!errlog

!process 0 0

!process 0 7

For techniques that can be used to read specific kinds of information from a dump file, see [Extracting Information from a Dump File](#).

User-Mode Dump Files

5/26/2017 • 1 min to read • [Edit Online](#)

This section includes:

[Varieties of User-Mode Dump Files](#)

[Creating a User-Mode Dump File](#)

[Analyzing a User-Mode Dump File](#)

[Send comments about this topic to Microsoft](#)

Varieties of User-Mode Dump Files

5/26/2017 • 1 min to read • [Edit Online](#)

There are several kinds of user-mode crash dump files, but they are divided into two categories:

[Full User-Mode Dumps](#)

[Minidumps](#)

The difference between these dump files is one of size. Minidumps are usually more compact, and can be easily sent to an analyst.

Note Much information can be obtained by analyzing a dump file. However, no dump file can provide as much information as actually debugging the crash directly with a debugger.

[Send comments about this topic to Microsoft](#)

Full User-Mode Dumps

5/26/2017 • 1 min to read • [Edit Online](#)

A *full user-mode dump* is the basic user-mode dump file.

This dump file includes the entire memory space of a process, the program's executable image itself, the handle table, and other information that will be useful to the debugger.

It is possible to "shrink" a full user-mode dump file into a minidump. Simply load the dump file into the debugger and then use the **.dump (Create Dump File)** command to save a new dump file in minidump format.

Note Despite their names, the largest "minidump" file actually contains more information than the full user-mode dump. For example, **.dump /mf** or **.dump /ma** will create a larger and more complete file than **.dump /f**.

In user mode, **.dump /m[*MiniOptions*]** is the best choice. The dump files created with this switch can vary in size from very small to very large. By specifying the proper *MiniOptions* you can control exactly what information is included.

[Send comments about this topic to Microsoft](#)

Minidumps

5/26/2017 • 3 min to read • [Edit Online](#)

A user-mode dump file that includes only selected parts of the memory associated with a process is called a *minidump*.

The size and contents of a minidump file vary depending on the program being dumped and the application doing the dumping. Sometimes, a minidump file is fairly large and includes the full memory and handle table. Other times, it is much smaller -- for example, it might only contain information about a single thread, or only contain information about modules that are actually referenced in the stack.

The name "minidump" is misleading, because the largest minidump files actually contain more information than the "full" user-mode dump. For example, **.dump /mf** or **.dump /ma** will create a larger and more complete file than **.dump /f**. For this reason, **.dump /m[*MiniOptions*]** recommended over **.dump /f** for all user-mode dump file creation.

If you are creating a minidump file with the debugger, you can choose exactly what information to include. A simple **.dump /m** command will include basic information about the loaded modules that make up the target process, thread information, and stack information. This can be modified by using any of the following options:

.DUMP OPTION	EFFECT ON DUMP FILE
/ma	Creates a minidump with all optional additions. The /ma option is equivalent to /mffhut -- it adds full memory data, handle data, unloaded module information, basic memory information, and thread time information to the minidump.
/mf	Adds full memory data to the minidump. All accessible committed pages owned by the target application will be included.
/mF	Adds all basic memory information to the minidump. This adds a stream to the minidump that contains all basic memory information, not just information about valid memory. This allows the debugger to reconstruct the complete virtual memory layout of the process when the minidump is being debugged.
/mh	Adds data about the handles associated with the target application to the minidump.
/mu	Adds unloaded module information to the minidump. This is only available in Windows Server 2003 and later versions of Windows.

DUMP OPTION	EFFECT ON DUMP FILE
/mt	Adds additional thread information to the minidump. This includes thread times, which can be displayed by using .ttime (Display Thread Times) when debugging the minidump.
/mi	Adds <i>secondary memory</i> to the minidump. Secondary memory is any memory referenced by a pointer on the stack or backing store, plus a small region surrounding this address.
/mp	Adds process environment block (PEB) and thread environment block (TEB) data to the minidump. This can be useful if you need access to Windows system information regarding the application's processes and threads.
/mw	Adds all committed read-write private pages to the minidump.
/md	Adds all read-write data segments within the executable image to the minidump.
/mc	Adds code sections within images.
/mr	Deletes from the minidump those portions of the stack and store memory that are not useful for recreating the stack trace. Local variables and other data type values are deleted as well. This option does not make the minidump smaller (since these memory sections are simply zeroed), but it is useful if you wish to protect the privacy of other applications.
/mR	Deletes the full module paths from the minidump. Only the module <i>names</i> will be included. This is a useful option if you wish to protect the privacy of the user's directory structure.
/mk "FileName"	(Windows Vista only) Creates a kernel-mode minidump in addition to the user-mode minidump. The kernel-mode minidump will be restricted to the same threads that are stored in the user-mode minidump. <i>FileName</i> must be enclosed in quotation marks.

These options can be combined. For example, the command **.dump /mfiu** can be used to create a fairly large minidump, or the command **.dump /mrR** can be used to create a minidump that preserves the user's privacy. For full syntax details, see [.dump \(Create Dump File\)](#).

For details on the internals of minidump files, see the DbgHelp Reference in the Microsoft Windows SDK.

Creating a User-Mode Dump File

5/26/2017 • 1 min to read • [Edit Online](#)

There are several different tools that can be used to create a user-mode dump file: CDB, WinDbg, Windows Error Reporting (WER), UserDump, and ADPlus.

This section includes:

[Choosing the Best Tool](#)

[CDB and WinDbg](#)

[UserDump](#)

For information about creating a user-mode dump file through ADPlus, see [ADPlus](#).

For information about creating a user-mode dump file through WER, see [Windows Error Reporting](#).

[Send comments about this topic to Microsoft](#)

Choosing the Best Tool

5/26/2017 • 1 min to read • [Edit Online](#)

There are several different tools that can create user-mode dump files. In most cases, ADPlus is the best tool to use.

The following table shows the features of each tool.

FEATURE	ADPLUS	WINDOWS ERROR REPORTING	CDB AND WINDBG	USERDUMP
Creating a dump file when an application crashes (postmortem debugging)	Yes	Yes	Yes	Yes
Creating a dump file when an application "hangs" (stops responding but does not actually crash)	Yes	No	Yes	Yes
Creating a dump file when an application encounters an exception	Yes	Yes	Yes	Yes
Creating a dump file while an application is running normally	No	No	Yes	No
Creating a dump file from an application that fails during startup	No	No	Yes	Yes
Shrinking an existing dump file	No	No	Yes	No

[Send comments about this topic to Microsoft](#)

CDB and WinDbg

5/26/2017 • 1 min to read • [Edit Online](#)

CDB and WinDbg can create user-mode dump files in a variety of ways.

Creating a Dump File Automatically

When an application error occurs, Windows can respond in several different ways, depending on the postmortem debugging settings. If these settings instruct a debugging tool to create a dump file, a user-mode memory dump file will be created. For more information, see [Enabling Postmortem Debugging](#).

Creating Dump Files While Debugging

When CDB or WinDbg is debugging a user-mode application, you can also the **.dump (Create Dump File)** command to create a dump file.

This command does not cause the target application to terminate. By selecting the proper command options, you can create a minidump file that contains exactly the amount of information you wish.

Shrinking an Existing Dump File

CDB and WinDbg can also be used to *shrink* a dump file. To do this, begin debugging an existing dump file, and then use the **.dump** command to create a dump file of smaller size.

[Send comments about this topic to Microsoft](#)

UserDump

5/26/2017 • 1 min to read • [Edit Online](#)

The UserDump tool (Userdump.exe), also known as User-Mode Process Dump, can create user-mode dump files.

UserDump and its documentation are part of the OEM Support Tools package.

To download these tools, go to [Microsoft Support Article 253066](#) and follow the instructions on that page.

Analyzing a User-Mode Dump File

5/26/2017 • 1 min to read • [Edit Online](#)

This section includes:

[Analyzing a User-Mode Dump File with CDB](#)

[Analyzing a User-Mode Dump File with WinDbg](#)

[Send comments about this topic to Microsoft](#)

Analyzing a User-Mode Dump File with CDB

5/26/2017 • 2 min to read • [Edit Online](#)

User-mode memory dump files can be analyzed by CDB. The processor or Windows version that the dump file was created on does not need to match the platform on which CDB is being run.

Installing Symbol Files

Before analyzing the memory dump file, you will need to install the symbol files for the version of Windows that generated the dump file. These files will be used by the debugger you choose to use to analyze the dump file. For more information about the proper installation of symbol files, see [Installing Windows Symbol Files](#).

You will also need to install all the symbol files for the user-mode process, either an application or system service, that caused the system to generate the dump file. If this code was written by you, the symbol files should have been generated when the code was compiled and linked. If this is commercial code, check on the product CD-ROM or contact the software manufacturer for these particular symbol files.

Starting CDB

To analyze a dump file, start CDB with the **-z** command-line option:

```
cdb -y SymbolPath -i ImagePath -z DumpFileName
```

The **-v** option (verbose mode) is also useful. For a full list of options, see [CDB Command-Line Options](#).

You can also open a dump file after the debugger is running by using the [.opendump \(Open Dump File\)](#) command, followed with **g (Go)**. This allows you to debug multiple dump files at the same time.

It is possible to debug multiple dump files at the same time. This can be done by including multiple **-z** switches on the command line (each followed by a different file name), or by using [.opendump](#) to add additional dump files as debugger targets. For information about how to control a multiple-target session, see [Debugging Multiple Targets](#).

Dump files generally end with the extension .dmp or .mdmp. You can use network shares or Universal Naming Convention (UNC) file names for the memory dump file.

It is also common for dump files to be packed into a CAB file. If you specify the file name (including the .cab extension) after the **-z** option or as the argument to an [.opendump](#) command, the debugger can read the dump files directly out of the CAB. However, if there are multiple dump files stored in a single CAB, the debugger will only be able to read one of them. The debugger will not read any additional files from the CAB, even if they are symbol files or executables associated with the dump file.

Analyzing a Full User Dump File

Analysis of a full user dump file is similar to analysis of a live debugging session. See the [Debugger Commands](#) reference section for details on which commands are available for debugging dump files in user mode.

Analyzing Minidump Files

Analysis of a user-mode minidump file is done in the same way as a full user dump. However, since much less memory has been preserved, you are much more limited in the actions you can perform. Commands that attempt to access memory beyond what is preserved in the minidump file will not function properly.

Additional Techniques

For techniques that can be used to read specific kinds of information from a dump file, see [Extracting Information from a Dump File](#).

[Send comments about this topic to Microsoft](#)

Analyzing a User-Mode Dump File with WinDbg

5/26/2017 • 3 min to read • [Edit Online](#)

User-mode memory dump files can be analyzed by WinDbg. The processor or Windows version that the dump file was created on does not need to match the platform on which WinDbg is being run.

Installing Symbol Files

Before analyzing the memory dump file, you will need to install the symbol files for the version of Windows that generated the dump file. Additional Techniques

For techniques that can be used to read specific kinds of information from a dump file, see [Extracting Information from a Dump File](#).

[Send comments about this topic to Microsoft](#)

Extracting Information from a Dump File

5/31/2017 • 1 min to read • [Edit Online](#)

Certain kinds of information, such as the name of the target computer, are easily available during live debugging. When debugging a dump file it takes a little more work to determine this information.

Finding the Computer Name in a Kernel-Mode Dump File

If you need to determine the name of the computer on which the crash dump was made, you can use the **!peb** extension and look for the value of COMPUTERNAME in its output.

Or you can use the following command:

```
0: kd> x srv!SrvComputerName
be8ce2e8  srv!SrvComputerName  = _UNICODE_STRING "AIGM-MYCOMP-PUB01"
```

Finding the IP Address in a Kernel-Mode Dump File

To determine the IP address of the computer on which the crash dump was made, find a thread stack that shows some send/receive network activity. Open one of the send packets or receive packets. The IP address will be visible in that packet.

Finding the Process ID in a User-Mode Dump File

To determine the process ID of the target application from a user-mode dump file, use the **| (Process Status)** command. This will display all the processes being debugged at the time the dump was written. The process marked with a period (.) is the current process. Its process ID is given in hexadecimal after the **id:** notation.

CAB Files that Contain Paging Files Along with a Memory Dump

5/26/2017 • 1 min to read • [Edit Online](#)

A memory dump file can be placed in a cabinet (CAB) file along with paging files. When a Windows debugger analyzes the memory dump file, it can use the paging files to present a full view memory, including memory that was paged out when the dump file was created.

Suppose a CAB file named MyCab.cab contains these files:

Memory.dmp Cabmanifest.xml Pagefile.sys Also suppose Cabmanifest.xml looks like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<WatsonPageFileManifest>
  <Pagefiles>
    <Pagefile Name="pagefile.sys"></Pagefile>
  </Pagefiles>
</WatsonPageFileManifest>
```

You can open the CAB file by entering one of these commands:

- **windbg /z MyCab.cab**
- **kd /z MyCab.cab**

The debugger reads Cabmanifest.xml for a list of paging files that are to be included in the debugging session. In this example, there is only one paging file. The debugger converts the paging file to a Target Information File (TIF) file that it can use during the debugging session. Because the debugger has access to the TIF, it can display memory that was paged out at the time the dump file was created.

Regardless of how many paging files are in the CAB file, the debugger uses only the paging files that are listed in Cabmanifest.xml. Here's an example of a CAB manifest file that lists three paging files.

```
<?xml version="1.0" encoding="UTF-8"?>
<WatsonPageFileManifest>
  <Pagefiles>
    <Pagefile Name="pagefile1.sys"></Pagefile>
    <Pagefile Name="pagefile2.sys"></Pagefile>
    <Pagefile Name="swapfile.sys"></Pagefile>
  </Pagefiles>
</WatsonPageFileManifest>
```

In Cabmanifest.xml, the paging files must be listed in the same order that Windows uses them. That is, they must be listed in the order that they appear in the Registry.

The memory dump file that you put in the CAB file must be a complete memory dump. You can use Control Panel to configure Windows to create a complete memory dump when there is a crash. For example, in Windows 8 you can go to **Control Panel > System and Security > System > Advanced System Settings > Startup and Recovery**. As an alternative to using Control Panel, you can set the value of this registry entry to 1.

HKLM\SYSTEM\CurrentControlSet\Control\CrashControl\CrashDumpEnabled

Starting in Windows 8.1, you can configure Windows to preserve the contents of paging files when Windows restarts.

To specify that you want paging files to be saved when Windows restarts, set the value of this registry entry to 1.

HKLM\SYSTEM\CurrentControlSet\Control\CrashControl\SavePageFileContents

Debugging OCA minidump files

5/26/2017 • 3 min to read • [Edit Online](#)

Online Crash Analysis (OCA) is the reporting facility for [Windows Error Reporting \(WER\)](#) information. Your company can use OCA crash dumps to analyze customer problems.

Analyze dump files

Dump files are a snapshot of the state of the computer (or process) at the time of the crash.

To analyze this data, a developer must use a debugger that can read user minidump files. The debugger must also have access to both the images and symbols that match the contents of the dump file. Most developers are aware of the need to use matching symbols when debugging a live crash. However, when debugging a minidump, matching images must also be available for the debugger.

Matching images must be available because minidump files store very little information; they store only some of the volatile information at the time of the crash. They do not store the basic code streams that the computer loaded into memory. Instead, to save space, the minidump file stores only the name and time stamp of the images loaded on the crashing computer.

To examine the code that was running on the crashing computer, the debugger must be given access to the same binaries that the crashing computer was running. The debugger uses the name and time stamp stored in the minidump file to uniquely match and load the binaries when the developer wants to debug the crash.

After the images and symbols are loaded in the debugger, you can analyze the state of the system at the time of the crash, including data that was saved after the crash occurred. The minidump does not, however, reproduce the steps that led to the specific failure. Finding the root cause requires analyzing the driver's source code to determine what code path may have led to the failure. Experience has shown that a large percentage of failures can be understood and addressed by analyzing dump files and source code.

Use symbols to match executable code with source code

The best way to access matching images and symbols is to use the Microsoft symbol server. Symbols are data that enable the debugger to map the executable code back to the source code. When you build a program, the program's symbols are usually stored in symbol files. When a debugger analyzes a program, it needs to access the program's symbols.

Symbol files can include any or all of the following:

- The names and addresses of all functions.
- All data type, structure, and class definitions.
- The names, data types, and addresses of global variables.
- The names, data types, addresses, and scopes of local variables.
- The line number in the source code that corresponds to each binary instruction.

The [Windows Driver Kit \(WDK\)](#) includes tools that can be used to reduce the number of symbols in a symbol file. The symbol files that contain all of the source-level information are called full symbol files. The symbol files with reduced information are called stripped symbol files.

Because symbol data is crucial for getting meaningful crash information from Windows Error Report (WER) data, we encourage you to submit your symbols when you submit drivers to be signed. When symbols are submitted, they are stored on a server that synchronizes symbol data with the associated WER processes. With this storage

process, you can easily categorize the crashes reported in the minidump files and ultimately receive better data back from Microsoft.

Microsoft provides a symbol server on the Internet that you can use to analyze the Windows modules that are present in minidump files. The server includes stripped symbol files for Windows and a few other products. Microsoft has added the binaries for Windows XP and Windows Server 2003. You can use the Internet symbol server and the Debugging Tools for Windows to analyze minidump files.

Integrate WER into applications

Information on integrating WER into applications can be found on MSDN at [Using WER](#).

Bug Checks (Blue Screens)

5/31/2017 • 1 min to read • [Edit Online](#)

This section includes:

[General Tips for Blue Screens](#)

[Blue Screen Data](#)

[Bug Check Code Reference](#)

Note These topics are for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

[Send comments about this topic to Microsoft](#)

General Tips for Blue Screens

5/26/2017 • 1 min to read • [Edit Online](#)

If your computer stops working and displays a blue screen, the computer has shut down abruptly to protect itself from data loss. A hardware device, its driver, or related software might have caused this error. If your copy of Windows came with your computer, you may want to contact the manufacturer of your computer.

If you have experience with computers and want to try to recover from this error, follow the steps described in [Troubleshoot blue screen errors](#).

[Send comments about this topic to Microsoft](#)

Blue Screen Data

5/26/2017 • 8 min to read • [Edit Online](#)

Note This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Note If you are an IT professional or support agent, see this article for additional information, [Troubleshoot "blue screen" or Stop error problems before you contact Microsoft Support](#).

When Microsoft Windows encounters a condition that compromises safe system operation, the system halts. This condition is called a *bug check*. It is also commonly referred to as a *system crash*, a *kernel error*, or a *stop error*.

If the OS were allowed to continue to run after the operating system integrity is compromised, it could corrupt data or compromise the security of the system.

If crash dumps are enabled on the system, a crash dump file is created.

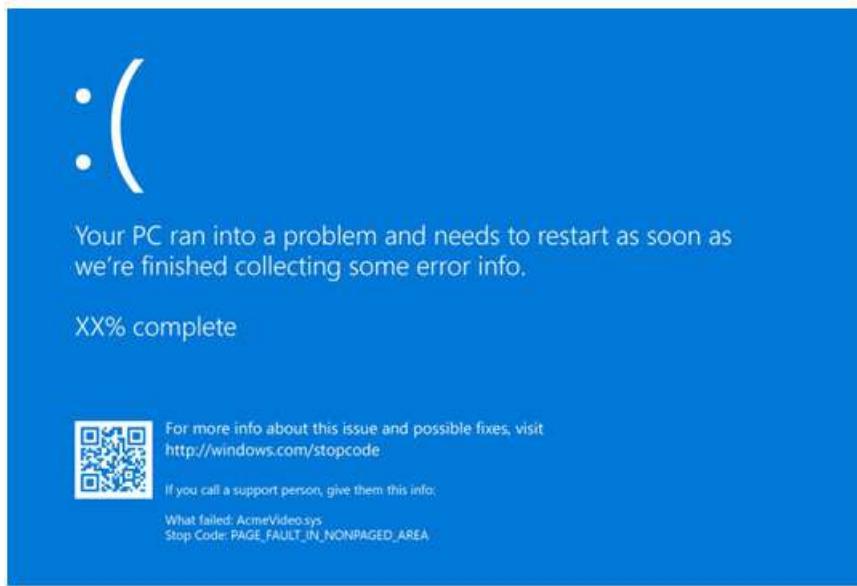

If a kernel debugger is attached and active, the system causes a break so that the debugger can be used to investigate the crash.

If no debugger is attached, a blue text screen appears with information about the error. This screen is called a *blue screen*, a *bug check screen*, or a *stop screen*.

If you are using an insider build of Windows, the text will be displayed on a green background.

The exact appearance of the blue screen depends on the cause of the error.

The following is an example of one possible blue screen:

The stop code is displayed such as **PAGE_FAULT_IN_NONPAGED_AREA**. When it is available, the module name of the code that was being executed is also displayed, such as AcmeVideo.sys.

If a [kernel-mode dump file](#) has been written, this will be indicated as well with a percentage complete count down as the dump is being written.

There is a stop code hex value associated with each stop code as listed in [Bug Check Code Reference](#).

Gathering the Stop Code Parameters

Each bug check code has four associated parameters that provide additional information. The parameters are described in [Bug Check Code Reference](#) for each stop code.

There are multiple ways to gather the four stop code parameters.

- Examine the Windows system log in the event viewer. The event properties for the BugCheck will list the four stop code parameters. For more information, see [Open Event Viewer](#).
- Load the generated dump file and use the **!analyze** command with the debugger attached. For more information, see [Analyzing a Kernel-Mode Dump File with WinDbg](#).
- Attach a kernel debugger to the faulting PC. When the stop code occurs, the debugger output will include the four parameters after the stop code hex value.

```
*****
*          Bugcheck Analysis
*
*****
Use !analyze -v to get detailed debugging information.

BugCheck 9F, {3, fffffe000f38c06a0, fffff803c596cad0, fffffe000f46a1010}

Implicit thread is now fffffe000`f4ca3040
Probably caused by : hidusb.sys
```

Bug Check Symbolic Names

DRIVER_POWER_STATE_FAILURE is the Bug Check Symbolic Name, with an associated bug check code of 9F. The stop code hex value associated with the Bug Check Symbolic Name is listed in the [Bug Check Code Reference](#).

Reading Bug Check Information from the Debugger

If a debugger is attached, a bug check will cause the target computer to break into the debugger. In this case, the blue screen may not appear immediately, the full details on this crash will be sent to the debugger and appear in the debugger window. To see this information a second time, use the [.bugcheck \(Display Bug Check Data\)](#) command or the **!analyze** extension command.

Kernel Debugging and Crash Dump Analysis

Kernel debugging is especially useful when other troubleshooting techniques fail, or for a recurring problem. Remember to capture the exact text in the bug check information section of the error message. To isolate a complex problem and develop a viable workaround, it is useful to record the exact actions that lead to the failure.

The **!analyze** debug extension displays information about the bug check and can be very helpful in determining the root cause.

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

[Analyzing a Kernel-Mode Dump File with WinDbg](#)

[Using the !analyze Extension and !analyze](#)

The Defrag Tools show on Channel 9 - <https://channel9.msdn.com/Shows/Defrag-Tools>

Using Driver Verifier to Gather Information

It is estimated that about three quarters of blue screens are caused by faulting drivers. Driver Verifier is a tool that runs in real time to examine the behavior of drivers. For example, Driver Verifier checks the use of memory resources, such as memory pools. If it sees errors in the execution of driver code, it proactively creates an exception to allow that part of the driver code to be further scrutinized. The driver verifier manager is built into Windows and is available on all Windows PCs. To start the driver verifier manager, type *Verifier* at a command prompt. You can configure which drivers you would like to verify. The code that verifies drivers adds overhead as it runs, so try and verify the smallest number of drivers as possible. For more information, see [Driver Verifier](#).

Tips for Software Engineers

When a bug check occurs as a result of code you have written, you should use the kernel debugger to analyze the problem, and then fix the bugs in your code. For full details, see the individual bug check code in the [Bug Check Code Reference](#) section.

However, you might also encounter bug checks that are not caused by your own code. In this case, you probably will not be able to fix the actual cause of the problem, so your goal should be to work around the problem, and if possible isolate and remove the hardware or software component that is at fault.

Many problems can be resolved through basic troubleshooting procedures, such as verifying instructions, reinstalling key components, and verifying file dates. Also, the Event Viewer, the Sysinternals diagnostic tools and network monitoring tools might isolate and resolve these issues.

For general troubleshooting of Windows bug check codes, follow these suggestions:

- If you recently added hardware to the system, try removing or replacing it. Or check with the manufacturer to see if any patches are available.
- If new device drivers or system services have been added recently, try removing or updating them. Try to determine what changed in the system that caused the new bug check code to appear.
- Look in **Device Manager** to see if any devices are marked with the exclamation point (!). Review the events log displayed in driver properties for any faulting driver. Try updating the related driver.
- Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- Run the Windows Memory Diagnostics tool, to test the memory. In the control panel search box, type Memory, and then click **Diagnose your computer's memory problems**. After the test is run, use Event viewer to view the results under the System log. Look for the *MemoryDiagnostics-Results* entry to view the results.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- Run a virus detection program. Viruses can infect all types of hard disks formatted for Windows, and resulting disk corruption can generate system bug check codes. Make sure the virus detection program checks the Master Boot Record for infections.
- Use the scan disk utility to confirm that there are no file system errors. Right click on the drive you want to scan and select **Properties**. Click on **Tools**. Click the **Check now** button.
- Use the System File Checker tool to repair missing or corrupted system files. The System File Checker is a utility in Windows that allows users to scan for corruptions in Windows system files and restore corrupted files. Use the following command to run the System File Checker tool (SFC.exe).

```
SFC /scannow
```

For more information, see [Use the System File Checker tool to repair missing or corrupted system files](#).

- Confirm that there is sufficient free space on the hard drive. The operating system and some applications require sufficient free space to create swap files and for other functions. Based on the system configuration, the exact requirement varies, but it is normally a good idea to have 10% to 15% free space available.
- Verify that the system has the latest Service Pack installed. To detect which Service Pack, if any, is installed on your system, click **Start**, click **Run**, type **winver**, and then press **ENTER**. The **About Windows** dialog box displays the Windows version number and the version number of the Service Pack, if one has been installed.
- Check with the manufacturer to see if an updated system BIOS or firmware is available.
- Disable BIOS memory options such as caching or shadowing.
- For PCs, make sure that all expansion boards are properly seated and all cables are completely connected.

Using Safe Mode

Consider using Safe Mode when removing or disabling components. Using Safe Mode loads only the minimum required drivers and system services during the Windows startup. To enter Safe Mode, use **Update and Security** in Settings. Select **Recovery->Advanced startup** to boot to maintenance mode. At the resulting menu, choose **Troubleshoot-> Advanced Options -> Startup Settings -> Restart**. After Windows restarts to the **Startup Settings** screen, select option, 4, 5 or 6 to boot to Safe Mode.

Safe Mode may be available by pressing a function key on boot, for example F8. Refer to information from the manufacturer for specific startup options.

Forced KeBugCheck

To deliberately cause a bug check from a kernel-mode driver, you need to pass the bug check's symbolic name to the **KeBugCheck** or **KeBugCheckEx** function. This should only be done in circumstances where no other option is available. For more details on these functions, see the Windows Driver Kit.

Bug Check Code Reference

5/26/2017 • 4 min to read • [Edit Online](#)

This section contains descriptions of the common bug checks, including the parameters passed to the blue screen. It also describes how you can diagnose the fault which led to the bug check, and possible ways to deal with the error.

Note This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

If a specific bug check code does not appear in this reference, use the **!analyze** extension command (in kernel mode) with the following syntax:

!analyze -show Code.

This will display information about the specified bug check. If your default radix is not 16, you should prefix *Code* with "0x".

The following table shows the code and name of each bug check.

CODE	NAME
0x00000001	APC_INDEX_MISMATCH
0x00000002	DEVICE_QUEUE_NOT_BUSY
0x00000003	INVALID_AFFINITY_SET

Bug Check 0x1: APC_INDEX_MISMATCH

5/26/2017 • 2 min to read • [Edit Online](#)

The APC_INDEX_MISMATCH bug check has a value of 0x00000001. This indicates that there has been a mismatch in the APC (asynchronous procedure calls) state index.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

APC_INDEX_MISMATCH Parameters

PARAMETER	DESCRIPTION
1	The address of the system function (system call) or worker routine.
2	The value of the current thread's ApcStateIndex field.
3	The value of current thread's CombinedApcDisable field. This field consists of two separate 16-bit fields: <i>(Thread->SpecialApcDisable << 16) Thread->KernelApcDisable</i> .
4	Call type (0 - system call, 1 - worker routine).

Cause

The most common cause of this bug check is when a file system or driver has a mismatched sequence of calls to disable and re-enable APCs. The key data item is the *Thread->CombinedApcDisable* field. The **CombinedApcDisable** field consists of two separate 16-bit fields: **SpecialApcDisable** and **KernelApcDisable**. A negative value of either field indicates that a driver has disabled special or normal APCs (respectively) without re-enabling them. A positive value indicates that a driver has enabled special or normal APCs too many times.

Resolution

The **!analyze** debug extension displays information about the bug check and can be very helpful in determining the root cause.

You can use the **!apc** extension to displays the contents of one or more asynchronous procedure calls (APCs).

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- For additional general troubleshooting information, see [Blue Screen Data](#).

Remarks

This is a kernel internal error. This error occurs on exit from a system call. A possible cause for this bug check is when a file system or driver has a mismatched sequence of system calls to enter or leave guarded or critical regions. For example, each call to [KeEnterCriticalSection](#) must have a matching call to [KeLeaveCriticalSection](#). If you are developing a driver, you can use [Static Driver Verifier](#), a static analysis tool available in the Windows Driver Kit, to detect problems in your code before you ship your driver. Run Static Driver Verifier with the [CriticalRegions](#) rule to verify that your source code uses these system calls in correct sequence.

Bug Check 0x2: DEVICE_QUEUE_NOT_BUSY

5/26/2017 • 1 min to read • [Edit Online](#)

The DEVICE_QUEUE_NOT_BUSY bug check has a value of 0x00000002.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x3: INVALID_AFFINITY_SET

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_AFFINITY_SET bug check has a value of 0x00000003.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x4: INVALID_DATA_ACCESS_TRAP

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_DATA_ACCESS_TRAP bug check has a value of 0x00000004.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x5: INVALID_PROCESS_ATTACH_ATTEMPT

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_PROCESS_ATTACH_ATTEMPT bug check has a value of 0x00000005. This generally indicates that the thread was attached to a process in a situation where that is not allowed. For example, this bug check could occur if **KeAttachProcess** was called when the thread was already attached to a process (which is illegal), or if the thread returned from certain function calls in an attached state (which is invalid).

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_PROCESS_ATTACH_ATTEMPT Parameters

PARAMETER	DESCRIPTION
1	The pointer to the dispatcher object for the target process, or if the thread is already attached, the pointer to the object for the original process.
2	The pointer to the dispatcher object of the process that the current thread is currently attached to.
3	The value of the thread's APC state index.
4	A non-zero value indicates that a DPC is running on the current processor.

Remarks

This bug check can occur if the driver calls the **KeAttachProcess** function and the thread is already attached to another process. It is better to use the **KeStackAttachProcess** function. If the current thread was already attached to another process, the **KeStackAttachProcess** function saves the current APC state before it attaches the current thread to the new process.

Bug Check 0x6: INVALID_PROCESS_DETACH_ATTEMPT

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_PROCESS_DETACH_ATTEMPT bug check has a value of 0x00000006.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x7: INVALID_SOFTWARE_INTERRUPT

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_SOFTWARE_INTERRUPT bug check has a value of 0x00000007.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x8: IRQL_NOT_DISPATCH_LEVEL

5/26/2017 • 1 min to read • [Edit Online](#)

The IRQL_NOT_DISPATCH_LEVEL bug check has a value of 0x00000008.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x9: IRQL_NOT_GREATER_OR_EQUAL

5/26/2017 • 1 min to read • [Edit Online](#)

The IRQL_NOT_GREATER_OR_EQUAL bug check has a value of 0x00000009.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0xA: IRQL_NOT_LESS_OR_EQUAL

5/26/2017 • 5 min to read • [Edit Online](#)

The IRQL_NOT_LESS_OR_EQUAL bug check has a value of 0x0000000A. This indicates that Microsoft Windows or a kernel-mode driver accessed paged memory at an invalid address while at a raised interrupt request level (IRQL). This is typically either a bad pointer or a pageability problem.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

IRQL_NOT_LESS_OR_EQUAL Parameters

PARAMETER	DESCRIPTION
1	<p>The virtual memory address that could not be accessed.</p> <p>Use !pool on this address to see whether it's Paged pool. These commands, may also be useful in gathering information about the failure: !pte, !address, and In (List Nearest Symbols).</p>
2	<p>IRQL at time of the fault.</p> <p>VALUES:</p> <p>2 : The IRQL was DISPATCH_LEVEL at the time of the fault. END_VALUES</p>

PARAMETER	DESCRIPTION
3	<p>Bitfield describing the operation that caused the fault.</p> <p>Bit 0:</p> <p>VALUES:</p> <p>0: Read operation</p> <p>1: Write operation</p> <p>Bit 3: (Only available on chipsets that support this level of reporting.)</p> <p>VALUES:</p> <p>0: Not an execute operation</p> <p>1: Execute operation</p> <p>Bit 0 and Bit 3 combined values:</p> <p>0x0 : Fault trying to READ from the address in parameter 1.</p> <p>0x1 : Fault trying to WRITE to the address in parameter 1.</p> <p>0x8 : Fault trying to EXECUTE code from the address in parameter 1.</p> <p>This value is usually caused by:</p> <ul style="list-style-type: none"> • Calling a function that cannot be called at DISPATCH_LEVEL while at DISPATCH_LEVEL • Forgetting to release a spinlock • Marking code as pageable when it must be non-pageable (e.g., because the code acquires a spinlock, or is called in a DPC)
4	<p>The instruction pointer at the time of the fault.</p> <p>Use the In (List Nearest Symbols) command on this address to see the name of the function.</p>

Cause

Bug check 0xA is usually caused by kernel mode device drivers using improper addresses.

This bug check indicates that an attempt was made to access an invalid address while at a raised interrupt request level (IRQL). This is either a bad memory pointer or a pageability problem with the device driver code.

1. If parameter 1 is less than 0x1000, then this is likely a NULL pointer dereference.
2. If !pool reports that parameter 1 is Paged pool, then the IRQL is too high to access this data. Run at a lower IRQL or allocate the data in NonPagedPool.
3. If parameter 3 indicates that this was an attempt to execute pageable code, then the IRQL is too high to call this function. Run at a lower IRQL or do not mark the code as pageable.
4. Otherwise, this may be a bad pointer, possibly caused by use-after-free or bit-flipping. Investigate the validity of parameter 1 with [!pte](#), [!address](#), and [In \(List Nearest Symbols\)](#).

Resolution

If a kernel debugger is available, obtain a stack trace.

Gather Information

Examine the name of the driver if that was listed on the blue screen.

Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.

Driver Verifier

Driver Verifier is a tool that runs in real time to examine the behavior of drivers. For example, Driver Verifier checks the use of memory resources, such as memory pools. If it sees errors in the execution of driver code, it proactively creates an exception to allow that part of the driver code to be further scrutinized. The driver verifier manager is built into Windows and is available on all Windows PCs. To start the driver verifier manager, type *Verifier* at a command prompt. You can configure which drivers you would like to verify. The code that verifies drivers adds overhead as it runs, so try and verify the smallest number of drivers as possible. For more information, see [Driver Verifier](#).

Here is a debugging example:

```

Remarks

The error that generates this bug check usually occurs after the installation of a faulty device driver, system service, or BIOS.

If you encounter bug check 0xA while upgrading to a later version of Windows, this error might be caused by a device driver, a system service, a virus scanner, or a backup tool that is incompatible with the new version.

Resolving a faulty hardware problem: If hardware has been added to the system recently, remove it to see if the error recurs. If existing hardware has failed, remove or replace the faulty component. You should run hardware diagnostics supplied by the system manufacturer. For details on these procedures, see the owner's manual for your computer.

Resolving a faulty system service problem: Disable the service and confirm that this resolves the error. If so, contact the manufacturer of the system service about a possible update. If the error occurs during system startup, investigate the Windows repair options. For more information, see [Recovery options in Windows 10](#).

Resolving an antivirus software problem: Disable the program and confirm that this resolves the error. If it does, contact the manufacturer of the program about a possible update.

For general blue screen troubleshooting information, see [Blue Screen Data](#).

Bug Check 0xB: NO_EXCEPTION_HANDLING_SUPPORT

5/26/2017 • 1 min to read • [Edit Online](#)

The NO_EXCEPTION_HANDLING_SUPPORT bug check has a value of 0x0000000B.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0xC: MAXIMUM_WAIT_OBJECTS_EXCEEDED

5/26/2017 • 1 min to read • [Edit Online](#)

The MAXIMUM_WAIT_OBJECTS_EXCEEDED bug check has a value of 0x0000000C. This indicates that the current thread exceeded the permitted number of wait objects.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MAXIMUM_WAIT_OBJECTS_EXCEEDED Parameters

None

Cause

This bug check results from the improper use of **KeWaitForMultipleObjects** or **FsRtlCancellableWaitForMultipleObjects**.

The caller may pass a pointer to a buffer in this routine's *WaitBlockArray* parameter. The system will use this buffer to keep track of wait objects.

If a buffer is supplied, the *Count* parameter may not exceed MAXIMUM_WAIT_OBJECTS. If no buffer is supplied, the *Count* parameter may not exceed THREAD_WAIT_OBJECTS.

If the value of *Count* exceeds the allowable value, this bug check is issued.

Bug Check 0xD: MUTEX_LEVEL_NUMBER_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The MUTEX_LEVEL_NUMBER_VIOLATION bug check has a value of 0x0000000D.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0xE: NO_USER_MODE_CONTEXT

5/26/2017 • 1 min to read • [Edit Online](#)

The NO_USER_MODE_CONTEXT bug check has a value of 0x0000000E.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0xF: SPIN_LOCK_ALREADY_OWNED

5/26/2017 • 1 min to read • [Edit Online](#)

The SPIN_LOCK_ALREADY_OWNED bug check has a value of 0x0000000F. This indicates that a request for a spin lock has been initiated when the spin lock was already owned.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SPIN_LOCK_ALREADY_OWNED Parameters

None

Cause

Typically, this error is caused by a recursive request for a spin lock. It can also occur if something similar to a recursive request for a spin lock has been initiated--for example, when a spin lock has been acquired by a thread, and then that same thread calls a function, which also tries to acquire a spin lock. The second attempt to acquire a spin lock is not blocked in this case because doing so would result in an unrecoverable deadlock. If the calls are made on more than one processor, then one processor will be blocked until the other processor releases the lock.

This error can also occur, without explicit recursion, when all threads and all spin locks are assigned an IRQL. Spin lock IRQLs are always greater than or equal to DPC level, but this is not true for threads. However, a thread that is holding a spin lock must maintain an IRQL greater than or equal to that of the spin lock. Decreasing the thread IRQL below the IRQL level of the spin lock that it is holding allows another thread to be scheduled on the processor. This new thread could then attempt to acquire the same spin lock.

Resolution

Ensure that you are not recursively acquiring the lock. And, for threads that hold a spin lock, ensure that you are not decreasing the thread IRQL to a level below the IRQL of the spin lock that it is holding.

Bug Check 0x10: SPIN_LOCK_NOT OWNED

5/26/2017 • 1 min to read • [Edit Online](#)

The SPIN_LOCK_NOT OWNED bug check has a value of 0x00000010.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x11: THREAD_NOT_MUTEX_OWNER

5/26/2017 • 1 min to read • [Edit Online](#)

The THREAD_NOT_MUTEX_OWNER bug check has a value of 0x00000011.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x12: TRAP_CAUSE_UNKNOWN

5/26/2017 • 1 min to read • [Edit Online](#)

The TRAP_CAUSE_UNKNOWN bug check has a value of 0x00000012. This indicates that an unknown exception has occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

TRAP_CAUSE_UNKNOWN Parameters

PARAMETER	DESCRIPTION
1	The unexpected interrupt
2	The unknown floating-point exception
3	The enabled and asserted status bits. See the processor definition for details.
4	Reserved

Bug Check 0x13: EMPTY_THREAD_REAPER_LIST

5/26/2017 • 1 min to read • [Edit Online](#)

The EMPTY_THREAD_REAPER_LIST bug check has a value of 0x00000013.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x14: CREATE_DELETE_LOCK_NOT_LOCKED

5/26/2017 • 1 min to read • [Edit Online](#)

The CREATE_DELETE_LOCK_NOT_LOCKED bug check has a value of 0x00000014.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x15: LAST_CHANCE_CALLED_FROM_KMODE

5/26/2017 • 1 min to read • [Edit Online](#)

The LAST_CHANCE_CALLED_FROM_KMODE bug check has a value of 0x00000015.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x16: CID_HANDLE_CREATION

5/26/2017 • 1 min to read • [Edit Online](#)

The CID_HANDLE_CREATION bug check has a value of 0x00000016.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x17: CID_HANDLE_DELETION

5/26/2017 • 1 min to read • [Edit Online](#)

The CID_HANDLE_DELETION bug check has a value of 0x00000017.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x18: REFERENCE_BY_POINTER

5/26/2017 • 2 min to read • [Edit Online](#)

The REFERENCE_BY_POINTER bug check has a value of 0x00000018. This indicates that the reference count of an object is illegal for the current state of the object.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

REFERENCE_BY_POINTER Parameters

PARAMETER	DESCRIPTION
1	Object type of the object whose reference count is being lowered.
2	Object whose reference count is being lowered.
3	Reserved
4	Reserved

Cause

The reference count of an object is illegal for the current state of the object. Each time a driver uses a pointer to an object, the driver calls a kernel routine to increase the reference count of the object by one. When the driver is done with the pointer, the driver calls another kernel routine to decrease the reference count by one.

Drivers must match calls to the routines that increase (*reference*) and decrease (*dereference*) the reference count. This bug check is caused by an inconsistency in the object's reference count. Typically, the inconsistency is caused by a driver that decreases the reference count of an object too many times, making extra calls that dereference the object. This bug check can occur because an object's reference count goes to zero while there are still open handles to the object. It might also occur when the object's reference count drops below zero, whether or not there are open handles to the object.

Resolution

Make sure that the driver matches calls to the routines that increase and decrease the reference count of the object. Make sure that your driver does not make extra calls to routines that dereference the object (see Parameter 2).

You can use a debugger to help analyze this problem. For more information, see [Crash dump analysis using the Windows debuggers \(WinDbg\)](#). The **!analyze** debug extension displays information about the bug check and can be very helpful in determining the root cause.

To find the handle and pointer count on the object, use the **!object** debugger command.

```
kd> !object address
```

Where *address* is the address of the object given in Parameter 2.

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code.

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- For additional general troubleshooting information, see [Blue Screen Data](#).

(Developer Content) Bug Check 0x19: BAD_POOL_HEADER

5/26/2017 • 3 min to read • [Edit Online](#)

The BAD_POOL_HEADER bug check has a value of 0x00000019. This indicates that a pool header is corrupt.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BAD_POOL_HEADER Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x2	The pool entry being checked	The size of the pool block	0	<p>The special pool pattern check failed.</p> <p>(The owner has likely corrupted the pool block.)</p>
0x3	The pool entry being checked	The read-back flink freelist value	The read-back blink freelist value	<p>The pool freelist is corrupt.</p> <p>(In a healthy list, the values of Parameters 2, 3, and 4 should be identical.)</p>
0x5	One of the pool entries	Reserved	The other pool entry	A pair of adjacent pool entries have headers that contradict each other. At least one of them is corrupt.
0x6	One incorrectly-calculated entry	Reserved	The bad entry that caused the miscalculation	The pool block header's previous size is too large.
0x7	0	Reserved	The bad pool entry	The pool block header size is corrupt.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x8	0	Reserved	The bad pool entry	The pool block header size is zero.
0x9	One incorrectly-calculated entry	Reserved	The bad entry that caused the miscalculation	The pool block header size is corrupted (it is too large).
0xA	The pool entry that should have been found	Reserved	The virtual address of the page that should have contained the pool entry	The pool block header size is corrupt.
0xD, 0xE, 0xF, 0x23, 0x24, 0x25	Reserved	Reserved	Reserved	The pool header of a freed block has been modified after it was freed. This is not typically the fault of the prior owner of the freed block; instead it is usually (but not always) due to the block preceding the freed block being overrun.
0x20	The pool entry that should have been found	The next pool entry	Reserved	The pool block header size is corrupt.
0x21	The pool pointer being freed	The number of bytes allocated for the pool block	The corrupted value found following the pool block	The data following the pool block being freed is corrupt. Typically this means the consumer (call stack) has overrun the block.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0X22	The address being freed	Reserved	Reserved	An address being freed does not have a tracking entry. This is usually because the call stack is trying to free a pointer that either has already been freed or was never allocated to begin with.

Cause

The pool is already corrupted at the time of the current request.

This may or may not be due to the caller.

Resolution

The internal pool links must be walked using the kernel debugger to figure out a possible cause of the problem.

Then you can use special pool for the suspect pool tags, or use Driver Verifier "Special Pool" option on the suspect driver. The [!analyze](#) extension may be of help in pinpointing the suspect driver, but this is frequently not the case with pool corrupters.

Use the steps described in [Blue Screen Data](#) to gather the Stop Code Parameters. Use the stop code parameters to determine the specific type of code behavior you are working to track down.

Driver Verifier

Driver Verifier is a tool that runs in real time to examine the behavior of drivers. If it sees errors in the execution of driver code, it proactively creates an exception to allow that part of the driver code to be further scrutinized. The driver verifier manager is built into Windows and is available on all Windows PCs. To start the driver verifier manager, type *Verifier* at a command prompt. You can configure which drivers you would like to verify. The code that verifies drivers adds overhead as it runs, so try and verify the smallest number of drivers as possible. For more information, see [Driver Verifier](#).

Windows Memory Diagnostics

If this Bug Check appears inconsistently, it could be related to faulty physical memory.

Run the Windows Memory Diagnostics tool, to test the memory. In the control panel search box, type Memory, and then click **Diagnose your computer's memory problems**. After the test is run, use Event viewer to view the results under the System log. Look for the *MemoryDiagnostics-Results* entry to view the results.

Bug Check 0x1A: MEMORY_MANAGEMENT

5/26/2017 • 3 min to read • [Edit Online](#)

The MEMORY_MANAGEMENT bug check has a value of 0x0000001A. This indicates that a severe memory management error occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MEMORY_MANAGEMENT Parameters

Parameter 1 is the only parameter of interest; this identifies the exact violation.

PARAMETER 1	CAUSE OF ERROR
0x1	The fork clone block reference count is corrupt. (This only occurs on checked builds of Windows.)
0x31	The image relocation fix-up table or code stream has been corrupted. This is probably a hardware error.
0x403	The page table and PFNs are out of sync. This is probably a hardware error, especially if parameters 3 & 4 differ by only a single bit.
0x411	A page table entry (PTE) has been corrupted. Parameter 2 is the address of the PTE.
0x777	The caller is unlocking a system cache address that is not currently locked. (This address was either never mapped or is being unlocked twice.)
0x778	The system is using the very last system cache view address, instead of preserving it.
0x780	The PTEs mapping the argument system cache view have been corrupted.
0x781	
0x1000	A caller of MmGetSystemAddressForMdl* tried to map a fully-cached physical page as non-cached. This action would cause a conflicting hardware translation buffer entry, and so it was refused by the operating system. Since the caller specified "bug check on failure" in the requesting MDL, the system had no choice but to issue a bug check in this instance.

PARAMETER 1	CAUSE OF ERROR
0x1010	The caller is unlocking a pageable section that is not currently locked. (This section was either never locked or is being unlocked twice.)
0x1233	A driver tried to map a physical memory page that was not locked. This is illegal because the contents or attributes of the page can change at any time. This is a bug in the code that made the mapping call. Parameter 2 is the page frame number of the physical page that the driver attempted to map.
0x1234	The caller is trying lock a nonexistent pageable section.
0x1235	The caller is trying to protect an MDL with an invalid mapping.
0x3451	The PTEs of a kernel thread stack that has been swapped out are corrupted.
0x5003	The working set free list is corrupt. This is probably a hardware error.
0x5100	The allocation bitmap is corrupt. The memory manager is about to overwrite a virtual address that was already in use.
0x8884	(Windows 7 only). Two pages on the standby list that were supposed to have identical page priority values do not, in fact, have identical page priority values. The differing values are captured in parameter 4.
0x8888 0x8889	Internal memory management structures are corrupted.
0x888A	Internal memory management structures (likely the PTE or PFN) are corrupted.
0x41283	The working set index encoded in the PTE is corrupted.
0x41284	A PTE or the working set list is corrupted.
0x41286	The caller is trying to free an invalid pool address.
0x41785	The working set list is corrupted.

PARAMETER 1	CAUSE OF ERROR
0x41287	An illegal page fault occurred while holding working set synchronization. Parameter 2 contains the referenced virtual address.
0x41790	A page table page has been corrupted. On a 64 bit version of Windows, parameter 2 contains the address of the PFN for the corrupted page table page. On a 32 bit version of Windows, parameter 2 contains a pointer to the number of used PTEs, and parameter 3 contains the number of used PTEs.
0x41792	A corrupted PTE has been detected. Parameter 2 contains the address of the PTE. Parameters 3/4 contain the low/high parts of the PTE.
0x61940	A PDE has been unexpectedly invalidated.
0x61946	The MDL being created is flawed. This almost always means the driver calling MmProbeAndLockPages is at fault. Typically the driver is attempting to create a Write MDL when it is being asked to process a paging Read.
0x03030303	The boot loader is broken. (This value applies only to Intel Itanium machines.)
Other	An unknown memory management error occurred.

Bug Check 0x1B: PFN_SHARE_COUNT

5/26/2017 • 1 min to read • [Edit Online](#)

The PFN_SHARE_COUNT bug check has a value of 0x0000001B.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x1C: PFN_REFERENCE_COUNT

5/26/2017 • 1 min to read • [Edit Online](#)

The PFN_REFERENCE_COUNT bug check has a value of 0x0000001C.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x1D: NO_SPIN_LOCK_AVAILABLE

5/26/2017 • 1 min to read • [Edit Online](#)

The NO_SPIN_LOCK_AVAILABLE bug check has a value of 0x0000001D.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x1E: KMODE_EXCEPTION_NOT_HANDLED

5/31/2017 • 5 min to read • [Edit Online](#)

The KMODE_EXCEPTION_NOT_HANDLED bug check has a value of 0x0000001E. This indicates that a kernel-mode program generated an exception which the error handler did not catch.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KMODE_EXCEPTION_NOT_HANDLED Parameters

PARAMETER	DESCRIPTION
1	The exception code that was not handled
2	The address at which the exception occurred
3	Parameter 0 of the exception
4	Parameter 1 of the exception

Cause

This is a common bug check. To interpret it, you must identify which exception was generated.

Common exception codes include:

- 0x80000002: STATUS_DATATYPE_MISALIGNMENT

An unaligned data reference was encountered.

- 0x80000003: STATUS_BREAKPOINT

A breakpoint or ASSERT was encountered when no kernel debugger was attached to the system.

- 0xC0000005: STATUS_ACCESS_VIOLATION

A memory access violation occurred. (Parameter 4 of the bug check is the address that the driver attempted to access.)

For a complete list of exception codes, see the ntstatus.h file located in the inc directory of the Windows Driver Kit.

Resolution

If you are not equipped to debug this problem, you can use some basic troubleshooting techniques described in [Blue Screen Data](#). If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.

If you plan to debug this problem, you may find it difficult to obtain a stack trace. Parameter 2 (the exception address) should pinpoint the driver or function that caused this problem.

If exception code 0x80000003 occurs, this indicates that a hard-coded breakpoint or assertion was hit, but the system was started with the **/NODEBUG** switch. This problem should rarely occur. If it occurs repeatedly, make sure a kernel debugger is connected and the system is started with the **/DEBUG** switch.

If exception code 0x80000002 occurs, the trap frame will supply additional information.

If the specific cause of the exception is unknown, the following should be considered:

Hardware incompatibility

Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).

Faulty device driver or system service

In addition, a faulty device driver or system service might be responsible for this error. Hardware issues, such as BIOS incompatibilities, memory conflicts, and IRQ conflicts can also generate this error.

If a driver is listed by name within the bug check message, disable or remove that driver. Disable or remove any drivers or services that were recently added. If the error occurs during the startup sequence and the system partition is formatted with NTFS file system, you might be able to use Safe Mode to disable the driver in Device Manager.

Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing bug check 0x1E. You should also run hardware diagnostics, especially the memory scanner, supplied by the system manufacturer. For details on these procedures, see the owner's manual for your computer.

The error that generates this message can occur after the first restart during Windows Setup, or after Setup is finished. A possible cause of the error is a system BIOS incompatibility. BIOS problems can be resolved by upgrading the system BIOS version.

To get a stack trace if the normal stack tracing procedures fail

1. Use the **kb (Display Stack Backtrace)** command to display parameters in the stack trace. Look for the call to **NT!PspUnhandledExceptionInSystemThread**. (If this function is not listed, see the note below.)
2. The first parameter to **NT!PspUnhandledExceptionInSystemThread** is a pointer to a structure, which contains pointers to an **except** statement:

```
typedef struct _EXCEPTION_POINTERS {
    PEXCEPTION_RECORD ExceptionRecord;
    PCONTEXT ContextRecord;
} EXCEPTION_POINTERS, *PEXCEPTION_POINTERS;

ULONG PspUnhandledExceptionInSystemThread(
    IN PEXCEPTION_POINTERS ExceptionPointers
)
```

Use the **dd (Display Memory)** command on that address to display the necessary data.

3. The first retrieved value is an exception record and the second is a context record. Use the **.exr (Display Exception Record)** command and the **.cxr (Display Context Record)** command with these two values as their arguments, respectively.
4. After the **.cxr** command executes, use the **kb** command to display a stack trace that is based on the context record information. This stack trace indicates the calling stack where the unhandled exception occurred.

Note This procedure assumes that you can locate **NT!PspUnhandledExceptionInSystemThread**. However, in some cases (such as an access violation crash) you will not be able to do this. In that case, look for **ntoskrnl!KiDispatchException**. The third parameter passed to this function is a trap frame address. Use the [.trap](#) ([Display Trap Frame](#)) command with this address to set the Register Context to the proper value. You can then perform stack traces and issue other commands.

Here is an example of bug check 0x1E on an x86 processor:

```
kd> .bugcheck          get the bug check data

Bug Check 0x1F: SHARED_RESOURCE_CONV_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The SHARED_RESOURCE_CONV_ERROR bug check has a value of 0x0000001F.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x20: KERNEL_APP_PENDNG_DURING_EXIT

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_APP_PENDNG_DURING_EXIT bug check has a value of 0x00000020. This indicates that an asynchronous procedure call (APC) was still pending when a thread exited.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_APP_PENDNG_DURING_EXIT Parameters

PARAMETER	DESCRIPTION
1	The address of the APC found pending during exit
2	The thread's APC disable count
3	The current IRQL
4	Reserved

Cause

The key data item is the APC disable count (Parameter 2) for the thread. If the count is nonzero, it will indicate the source of the problem.

The APC disable count is decremented each time a driver calls **KeEnterCriticalSection**, **FsRtlEnterFileSystem**, or acquires a mutex.

The APC disable count is incremented each time a driver calls **KeLeaveCriticalSection**, **KeReleaseMutex**, or **FsRtlExitFileSystem**.

Because these calls should always be in pairs, the APC disable count should be zero when a thread exits. A negative value indicates that a driver has disabled APC calls without re-enabling them. A positive value indicates that the reverse is true.

If you ever see this error, be very suspicious of all drivers installed on the machine -- especially unusual or non-standard drivers.

This current IRQL (Parameter 3) should be zero. If it is not, the driver's cancellation routine may have caused this bug check by returning at an elevated IRQL. In this case, carefully note what was running (and what was closing) at the time of the crash, and note all of the installed drivers at the time of the crash. The cause in this case is usually a severe bug in a driver.

Bug Check 0x21: QUOTA_UNDERFLOW

5/26/2017 • 1 min to read • [Edit Online](#)

The QUOTA_UNDERFLOW bug check has a value of 0x00000021. This indicates that quota charges have been mishandled by returning more quota to a particular block than was previously charged.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

QUOTA_UNDERFLOW Parameters

PARAMETER	DESCRIPTION
1	The process that was initially charged, if available.
2	The quota type. For the list of all possible quota type values, see the header file Ps.h in the Windows Driver Kit (WDK).
3	The initial charged amount of quota to return.
4	The remaining amount of quota that was not returned.

Bug Check 0x22: FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The FILE_SYSTEM bug check has a value of 0x00000022.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x23: FAT_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The FAT_FILE_SYSTEM bug check has a value of 0x00000023. This indicates that a problem occurred in the FAT file system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

FAT_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	If FatExceptionFilter is on the stack, this parameter specifies the address of the exception record.
3	If FatExceptionFilter is on the stack, this parameter specifies the address of the context record.
4	Reserved

Cause

One possible cause of this bug check is disk corruption. Corruption in the file system or bad blocks (sectors) on the disk can induce this error. Corrupted SCSI and IDE drivers can also adversely affect the system's ability to read and write to the disk, thus causing the error.

Another possible cause is depletion of nonpaged pool memory. If the nonpaged pool memory is completely depleted, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver requiring nonpaged pool memory can also trigger this error.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command with Parameter 3, and then use [kb \(Display Stack Backtrace\)](#).

To resolve a disk corruption problem: Check Event Viewer for error messages from SCSI and FASTFAT (System Log) or Autochk (Application Log) that might help pinpoint the device or driver that is causing the error. Try disabling any virus scanners, backup programs, or disk defragmenter tools that continually monitor the system. You should also run hardware diagnostics supplied by the system manufacturer. For details on these procedures, see the owner's manual for your computer. Run **Chkdsk /f /r** to detect and resolve any file system structural

corruption. You must restart the system before the disk scan begins on a system partition.

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This will increase the quantity of nonpaged pool memory available to the kernel.

Bug Check 0x24: NTFS_FILE_SYSTEM

5/26/2017 • 3 min to read • [Edit Online](#)

The NTFS_FILE_SYSTEM bug check has a value of 0x00000024. This indicates a problem occurred in ntfs.sys, the driver file that allows the system to read and write to NTFS drives.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NTFS_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	If NtfsExceptionFilter is on the stack, this parameter specifies the address of the exception record.
3	If NtfsExceptionFilter is on the stack, this parameter specifies the address of the context record.
4	Reserved

Cause

One possible cause of this bug check is disk corruption. Corruption in the NTFS file system or bad blocks (sectors) on the hard disk can induce this error. Corrupted hard drive (SATA/IDE) drivers can also adversely affect the system's ability to read and write to disk, thus causing the error.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command with Parameter 3, and then use [kb \(Display Stack Backtrace\)](#).

To resolve a disk corruption problem:

- Check Event Viewer for error messages related to the hard drive appearing in the System Log that might help pinpoint the device or driver that is causing the error.
- Try disabling any virus scanners, backup programs, or disk defragmenter tools that continually monitor the system.
- You should also run hardware diagnostics supplied by the system manufacturer related to the storage subsystem.
- Use the scan disk utility to confirm that there are no file system errors. Right click on the drive you want to

scan and select **Properties**. Click on **Tools**. Click the **Check now** button.

- Confirm that there is sufficient free space on the hard drive. The operating system and some applications require sufficient free space to create swap files and for other functions. Based on the system configuration, the exact requirement varies, but it is normally a good idea to have 10% to 15% free space available.
- Use the System File Checker tool to repair missing or corrupted system files. The System File Checker is a utility in Windows that allows users to scan for corruptions in Windows system files and restore corrupted files. Use the following command to run the System File Checker tool (SFC.exe).

```
SFC /scannow
```

For more information, see [Use the System File Checker tool to repair missing or corrupted system files](#).

- **Driver Verifier**

Driver Verifier is a tool that runs in real time to examine the behavior of drivers. If it sees errors in the execution of driver code, it proactively creates an exception to allow that part of the driver code to be further scrutinized. The driver verifier manager is built into Windows and is available on all Windows PCs. To start the driver verifier manager, type *Verifier* at a command prompt. You can configure which drivers you would like to verify. The code that verifies drivers adds overhead as it runs, so try and verify the smallest number of drivers as possible. For more information, see [Driver Verifier](#).

In the past, another possible cause of this stop code is depletion of nonpaged pool memory. If the nonpaged pool memory is completely depleted, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver requiring nonpaged pool memory can also trigger this error.

Bug Check 0x25: NPFS_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The NPFS_FILE_SYSTEM bug check has a value of 0x00000025. This indicates that a problem occurred in the NPFS file system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NPFS_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	Reserved
3	Reserved
4	Reserved

Cause

One possible cause of this bug check is depletion of nonpaged pool memory. If the nonpaged pool memory is completely depleted, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver requiring nonpaged pool memory can also trigger this error.

Resolution

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This will increase the quantity of nonpaged pool memory available to the kernel.

Bug Check 0x26: CDFS_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The CDFS_FILE_SYSTEM bug check has a value of 0x00000026. This indicates that a problem occurred in the CD file system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CDFS_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	If CdExceptionFilter is on the stack, this parameter specifies the address of the exception record.
3	If CdExceptionFilter is on the stack, this parameter specifies the address of the context record.
4	Reserved

Cause

One possible cause of this bug check is disk corruption. Corruption in the file system or bad blocks (sectors) on the disk can induce this error. Corrupted SCSI and IDE drivers can also adversely affect the system's ability to read and write to the disk, thus causing the error.

Another possible cause is depletion of nonpaged pool memory. If the nonpaged pool memory is completely depleted, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver requiring nonpaged pool memory can also trigger this error.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command with Parameter 3, and then use [kb \(Display Stack Backtrace\)](#).

To resolve a disk corruption problem: Check Event Viewer for error messages from SCSI and FASTFAT (System Log) or Autochk (Application Log) that might help pinpoint the device or driver that is causing the error. Try disabling any virus scanners, backup programs, or disk defragmenter tools that continually monitor the system. You should also run hardware diagnostics supplied by the system manufacturer. For details on these procedures, see the owner's manual for your computer. Run **Chkdsk /f /r** to detect and resolve any file system structural

corruption. You must restart the system before the disk scan begins on a system partition.

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This will increase the quantity of nonpaged pool memory available to the kernel.

Bug Check 0x27: RDR_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The RDR_FILE_SYSTEM bug check has a value of 0x00000027. This indicates that a problem occurred in the SMB redirector file system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

RDR_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	The high 16 bits (the first four hexadecimal digits after the "0x") identify the type of problem. Possible values include: 0xCA550000 RDBSS_BUG_CHECK_CACHESUP 0xC1EE0000 RDBSS_BUG_CHECK_CLEANUP 0xC10E0000 RDBSS_BUG_CHECK_CLOSE 0xBAAD0000 RDBSS_BUG_CHECK_NTEXCEPT
2	If RxExceptionFilter is on the stack, this parameter specifies the address of the exception record.
3	If RxExceptionFilter is on the stack, this parameter specifies the address of the context record.
4	Reserved

Cause

One possible cause of this bug check is depletion of nonpaged pool memory. If the nonpaged pool memory is completely depleted, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver requiring nonpaged pool memory can also trigger this error.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command with Parameter 3, and then use [kb \(Display Stack Backtrace\)](#).

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This will increase the quantity of nonpaged pool memory available to the kernel.

Bug Check 0x28: CORRUPT_ACCESS_TOKEN

5/26/2017 • 1 min to read • [Edit Online](#)

The CORRUPT_ACCESS_TOKEN bug check has a value of 0x00000028.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x29: SECURITY_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The SECURITY_SYSTEM bug check has a value of 0x00000029.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x2A: INCONSISTENT_IRP

5/26/2017 • 1 min to read • [Edit Online](#)

The INCONSISTENT_IRP bug check has a value of 0x0000002A. This indicates that an IRP was found to contain inconsistent information.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INCONSISTENT_IRP Parameters

PARAMETER	DESCRIPTION
1	The address of the IRP that was found to be inconsistent
2	Reserved
3	Reserved
4	Reserved

Cause

An IRP was discovered to be in an inconsistent state. Usually this means some field of the IRP was inconsistent with the remaining state of the IRP. An example would be an IRP that was being completed, but was still marked as being queued to a driver's device queue.

Remarks

This bug check code is not currently being used in the system, but exists for debugging purposes.

Bug Check 0x2B: PANIC_STACK_SWITCH

5/26/2017 • 1 min to read • [Edit Online](#)

The PANIC_STACK_SWITCH bug check has a value of 0x0000002B. This indicates that the kernel mode stack was overrun.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PANIC_STACK_SWITCH Parameters

PARAMETER	DESCRIPTION
1	The trap frame
2	Reserved
3	Reserved
4	Reserved

Cause

This error normally appears when a kernel-mode driver uses too much stack space. It can also appear when serious data corruption occurs in the kernel.

Bug Check 0x2C: PORT_DRIVER_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The PORT_DRIVER_INTERNAL bug check has a value of 0x0000002C.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x2D: SCSI_DISK_DRIVER_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The SCSI_DISK_DRIVER_INTERNAL bug check has a value of 0x0000002D.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x2E: DATA_BUS_ERROR

5/26/2017 • 2 min to read • [Edit Online](#)

The DATA_BUS_ERROR bug check has a value of 0x0000002E. This typically indicates that a parity error in system memory has been detected.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DATA_BUS_ERROR Parameters

PARAMETER	DESCRIPTION
1	Virtual address that caused the fault
2	Physical address that caused the fault
3	Processor status register (PSR)
4	Faulting instruction register (FIR)

Cause

This error is almost always caused by a hardware problem -- a configuration issue, defective hardware, or incompatible hardware.

The most common hardware problems that can cause this error are defective RAM, Level 2 (L2) RAM cache errors, or video RAM errors. Hard disk corruption can also cause this error.

This bug check can also be caused when a device driver attempts to access an address in the 0x8xxxxxx range that does not exist (in other words, that does not have a physical address mapping).

Resolution

Resolving a hardware problem: If hardware has recently been added to the system, remove it to see if the error recurs.

If existing hardware has failed, remove or replace the faulty component. You should run hardware diagnostics supplied by the system manufacturer to determine which hardware component has failed. For details on these procedures, see the owner's manual for your computer. Check that all adapter cards in the computer are properly seated. Use an ink eraser or an electrical contact treatment, available at electronics supply stores, to ensure that adapter card contacts are clean.

If the problem occurs on a newly installed system, check the availability of updates for the BIOS, the SCSI controller or network cards. Updates of this kind are typically available on the Web site or the bulletin board system (BBS) of the hardware manufacturer.

If the error occurs after installing a new or updated device driver, the driver should be removed or replaced. If,

under this circumstance, the error occurs during startup and the system partition is formatted with NTFS, you might be able to use Safe Mode to rename or delete the faulty driver.

If the driver is used as part of the system startup process in Safe Mode, you need to start the computer using the Recovery Console in order to access the file.

For additional error messages that might help pinpoint the device or driver that is causing the error, check the System Log in Event Viewer. Disabling memory caching or shadowing in the BIOS might also resolve this error. In addition, check the system for viruses, using any up-to-date commercial virus scanning software that examines the Master Boot Record of the hard disk. All Windows file systems can be infected by viruses.

Resolving a hard disk corruption problem: Run **Chkdsk /f /r** on the system partition. You must restart the system before the disk scan begins. If you cannot start the system due to the error, use the Recovery Console and run **Chkdsk /r**.

Warning If your system partition is formatted with the file allocation table (FAT) file system, the long filenames used by Windows can be damaged if Scandisk or another Microsoft MS-DOS-based hard disk tool is used to verify the integrity of your hard disk from MS-DOS. Always use the version of Chkdsk that matches your Windows version.

Bug Check 0x2F: INSTRUCTION_BUS_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The INSTRUCTION_BUS_ERROR bug check has a value of 0x0000002F.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x30: SET_OF_INVALID_CONTEXT

5/26/2017 • 1 min to read • [Edit Online](#)

The SET_OF_INVALID_CONTEXT bug check has a value of 0x00000030. This indicates that the stack pointer in a trap frame had an invalid value.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SET_OF_INVALID_CONTEXT Parameters

PARAMETER	DESCRIPTION
1	The new stack pointer
2	The old stack pointer
3	The trap frame address
4	0

Cause

This bug check occurs when some routine attempts to set the stack pointer in the trap frame to a lower value than the current stack pointer value.

If this error were not caught, it would cause the kernel to run with a stack pointer pointing to stack which is no longer valid.

Bug Check 0x31: PHASE0_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The PHASE0_INITIALIZATION_FAILED bug check has a value of 0x00000031. This indicates that system initialization failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PHASE0_INITIALIZATION_FAILED Parameters

None

Cause

System initialization failed at a very early stage.

Resolution

A debugger is required to analyze this.

Bug Check 0x32: PHASE1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The PHASE1_INITIALIZATION_FAILED bug check has a value of 0x00000032. This indicates that system initialization failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PHASE1_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	The NT status code that describes why the system initialization failed
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x33: UNEXPECTED_INITIALIZATION_CALL

5/26/2017 • 1 min to read • [Edit Online](#)

The UNEXPECTED_INITIALIZATION_CALL bug check has a value of 0x00000033.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x34: CACHE_MANAGER

5/26/2017 • 1 min to read • [Edit Online](#)

The CACHE_MANAGER bug check has a value of 0x00000034. This indicates that a problem occurred in the file system's cache manager.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CACHE_MANAGER Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	Reserved
3	Reserved
4	Reserved

Cause

One possible cause of this bug check is depletion of nonpaged pool memory. If the nonpaged pool memory is completely depleted, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver requiring nonpaged pool memory can also trigger this error.

Resolution

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This will increase the quantity of nonpaged pool memory available to the kernel.

Bug Check 0x35: NO_MORE_IRP_STACK_LOCATIONS

5/26/2017 • 1 min to read • [Edit Online](#)

The NO_MORE_IRP_STACK_LOCATIONS bug check has a value of 0x00000035. This bug check occurs when the **IoCallDriver** packet has no more stack locations remaining.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NO_MORE_IRP_STACK_LOCATIONS Parameters

PARAMETER	DESCRIPTION
1	Address of the IRP
2	Reserved
3	Reserved
4	Reserved

Cause

A higher-level driver has attempted to call a lower-level driver through the **IoCallDriver** interface, but there are no more stack locations in the packet. This will prevent the lower-level driver from accessing its parameters.

This is a disastrous situation, since the higher level driver is proceeding as if it has filled in the parameters for the lower level driver (as required). But since there is no stack location for the latter driver, the former has actually written off the end of the packet. This means that some other memory has been corrupted as well.

Bug Check 0x36: DEVICE_REFERENCE_COUNT_NOT_ZERO

5/26/2017 • 1 min to read • [Edit Online](#)

The DEVICE_REFERENCE_COUNT_NOT_ZERO bug check has a value of 0x00000036. This indicates that a driver attempted to delete a device object that still had a positive reference count.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DEVICE_REFERENCE_COUNT_NOT_ZERO Parameters

PARAMETER	DESCRIPTION
1	The address of the device object
2	Reserved
3	Reserved
4	Reserved

Cause

A device driver has attempted to delete one of its device objects from the system, but the reference count for that object was non-zero.

This means there are still outstanding references to the device. (The reference count indicates the number of reasons why this device object cannot be deleted.)

This is a bug in the calling device driver.

Bug Check 0x37: FLOPPY_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The FLOPPY_INTERNAL_ERROR bug check has a value of 0x00000037.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x38: SERIAL_DRIVER_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The SERIAL_DRIVER_INTERNAL bug check has a value of 0x00000038.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x39: SYSTEM_EXIT OWNED_MUTEX

5/26/2017 • 1 min to read • [Edit Online](#)

The SYSTEM_EXIT OWNED_MUTEX bug check has a value of 0x00000039. This indicates that the worker routine returned without releasing the mutex object that it owned.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SYSTEM_EXIT OWNED_MUTEX Parameters

PARAMETER	DESCRIPTION
1	The address of the worker routine that caused the error.
2	The parameter passed to the worker routine.
3	The address of the work item.
4	Reserved.

Cause

The worker routine returned while it still owned a mutex object. The current worker thread will proceed to run other unrelated work items, and the mutex will never be released.

Resolution

A debugger is required to analyze this problem. To find the driver that caused the error, use the **!n** (List Nearest Symbols) debugger command:

```
kd> !n address
```

Where address is the worker routine given in Parameter 1.

Bug Check 0x3A: SYSTEM_UNWIND_PREVIOUS_USER

5/26/2017 • 1 min to read • [Edit Online](#)

The SYSTEM_UNWIND_PREVIOUS_USER bug check has a value of 0x0000003A.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x3B: SYSTEM_SERVICE_EXCEPTION

5/26/2017 • 2 min to read • [Edit Online](#)

The SYSTEM_SERVICE_EXCEPTION bug check has a value of 0x0000003B. This indicates that an exception happened while executing a routine that transitions from non-privileged code to privileged code.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SYSTEM_SERVICE_EXCEPTION Parameters

PARAMETER	DESCRIPTION
1	The exception that caused the bug check
2	The address of the instruction that caused the bug check
3	The address of the context record for the exception that caused the bug check
4	0

Cause

The stop code indicates that executing code had an exception and the thread that was below it, is a system thread.

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in determining the root cause.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

[Analyzing a Kernel-Mode Dump File with WinDbg](#)

[Using the !analyze Extension and !analyze](#)

In the past, this error has been linked to excessive paged pool usage and may occur due to user-mode graphics drivers crossing over and passing bad data to the kernel code. If you suspect this is the case, use the pool options in driver verifier to gather additional information.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command with Parameter 3, and then use [kb \(Display Stack Backtrace\)](#). You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code.

For general troubleshooting of Windows bug check codes, follow these suggestions:

- If you recently added hardware to the system, try removing or replacing it. Or check with the manufacturer

to see if any patches are available.

- If new device drivers or system services have been added recently, try removing or updating them. Try to determine what changed in the system that caused the new bug check code to appear.
- Look in **Device Manager** to see if any devices are marked with the exclamation point (!). Review the events log displayed in driver properties for any faulting driver. Try updating the related driver.
- Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.
- For additional general troubleshooting information, see [Blue Screen Data](#).

Bug Check 0x3C: INTERRUPT_UNWIND_ATTEMPTED

5/26/2017 • 1 min to read • [Edit Online](#)

The INTERRUPT_UNWIND_ATTEMPTED bug check has a value of 0x0000003C.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x3D: INTERRUPT_EXCEPTION_NOT_HANDLED

5/26/2017 • 1 min to read • [Edit Online](#)

The INTERRUPT_EXCEPTION_NOT_HANDLED bug check has a value of 0x0000003D.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x3E:

MULTIPROCESSOR_CONFIGURATION_NOT_SUPPORTED

5/26/2017 • 1 min to read • [Edit Online](#)

The MULTIPROCESSOR_CONFIGURATION_NOT_SUPPORTED bug check has a value of 0x0000003E. This indicates that the system has multiple processors, but they are asymmetric in relation to one another.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MULTIPROCESSOR_CONFIGURATION_NOT_SUPPORTED Parameters

None

Cause

In order to be symmetric, all processors must be of the same type and level. This system contains processors of different types (for example, a Pentium processor and an 80486 processor).

Bug Check 0x3F: NO_MORE_SYSTEM_PTES

5/31/2017 • 1 min to read • [Edit Online](#)

The NO_MORE_SYSTEM_PTES bug check has a value of 0x0000003F. This is the result of a system which has performed too many I/O actions. This has resulted in fragmented system page table entries (PTE).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NO_MORE_SYSTEM_PTES Parameters

PARAMETER	DESCRIPTION
1	0: system expansion PTE type 1: nonpaged pool expansion PTE type
2	Size of memory request
3	Total free system PTEs
4	Total system PTEs

Cause

In almost all cases, the system is not actually out of PTEs. Rather, a driver has requested a large block of memory, but there is no contiguous block of sufficient size to satisfy this request.

Often video drivers will allocate large amounts of kernel memory that must succeed. Some backup programs do the same.

Resolution

A possible work-around: Modify the registry to increase the total number of system PTEs. If this does not help, remove any recently-installed software, especially backup utilities or disk-intensive applications.

Debugging the problem: The following method can be used to debug bug check 0x3F.

First, get a stack trace, and use the [!sysptes 3](#) extension command.

Then set **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management\TrackPtes** equal to DWORD 1, and reboot. This will cause the system to save stack traces.

This allows you to display more detailed information about the PTE owners. For example:

```

0: kd> !sysptes 4

0x2c47 System PTEs allocated to mapping locked pages

VA      MDL      PageCount  Caller/CallersCaller
f0e5db48 eb6ceef0      1 ntkrpamp!MmMapLockedPages+0x15/ntkrpamp!IopfCallDriver+0x35

.....

```

If the system runs out of PTEs again after the **TrackPtes** registry value has been set, **bug check 0xD8** (DRIVER_USED_EXCESSIVE_PTES) will be issued instead of 0x3F. The name of the driver causing this error will be displayed as well.

Bug Check 0x40: TARGET_MDL_TOO_SMALL

5/26/2017 • 1 min to read • [Edit Online](#)

The TARGET_MDL_TOO_SMALL bug check has a value of 0x00000040. This indicates that a driver has improperly used **IoBuildPartialMdl**.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

TARGET_MDL_TOO_SMALL Parameters

None

Cause

This is a driver bug. A driver has called the **IoBuildPartialMdl** function and passed it an MDL to map part of a source MDL, but the target MDL is not large enough to map the entire range of addresses requested.

Resolution

The source and target MDLs, as well as the address range length to be mapped, are the first, second, and fourth arguments to the **IoBuildPartialMdl** function. Therefore, doing a stack trace on this particular function might help during the debugging process. Ensure that your code is correctly calculating the necessary size for the target MDL for the address range length that you are passing to this function.

Bug Check 0x41: MUST_SUCCEED_POOL_EMPTY

5/26/2017 • 1 min to read • [Edit Online](#)

The MUST_SUCCEED_POOL_EMPTY bug check has a value of 0x00000041. This indicates that a kernel-mode thread has requested too much must-succeed pool.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MUST_SUCCEED_POOL_EMPTY Parameters

PARAMETER	DESCRIPTION
1	The size of the request that could not be satisfied
2	The number of pages used from nonpaged pool
3	The number of requests from nonpaged pool larger than PAGE_SIZE
4	The number of pages available

Cause

In Microsoft Windows 2000, only a small amount of must-succeed pool is permitted. In Windows XP and later, no driver is permitted to request must-succeed pool.

If a must-succeed request cannot be filled, this bug check is issued.

Resolution

Replace or rewrite the driver which is making the request. A driver should not request must-succeed pool. Instead, it should ask for normal pool and gracefully handle the scenario where the pool is temporarily empty.

The **kb (Display Stack Backtrace)** command will show the driver that caused the error.

Additionally, it is possible that a second component has depleted the must-succeed pool. To determine if this is the case, first use the **kb** command. Then use **!lvm 1** to display total pool usage, **!poolused 2** to display per-tag nonpaged pool usage, and **!poolused 4** to display per-tag paged pool usage. The component associated with the tag using the most pool is probably the source of the problem.

Bug Check 0x42: ATDISK_DRIVER_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The ATDISK_DRIVER_INTERNAL bug check has a value of 0x00000042.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x43: NO SUCH PARTITION

5/26/2017 • 1 min to read • [Edit Online](#)

The NO SUCH PARTITION bug check has a value of 0x00000043.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x44: MULTIPLE_IRP_COMPLETE_REQUESTS

5/26/2017 • 1 min to read • [Edit Online](#)

The MULTIPLE_IRP_COMPLETE_REQUESTS bug check has a value of 0x00000044. This indicates that a driver has tried to request an IRP be completed that is already complete.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MULTIPLE_IRP_COMPLETE_REQUESTS Parameters

PARAMETER	DESCRIPTION
1	The address of the IRP
2	Reserved
3	Reserved
4	Reserved

Cause

A driver has called **IoCompleteRequest** to ask that an IRP be completed, but the packet has already been completed.

Resolution

This is a tough bug to find because the simplest case -- a driver that attempted to complete its own packet twice -- is usually not the source of the problem. More likely, two separate drivers each believe that they own the packet, and each has attempted to complete it. The first request succeeds, and the second fails, resulting in this bug check.

Tracking down which drivers in the system caused the error is difficult, because the trail of the first driver has been covered by the second. However, the driver stack for the current request can be found by examining the device object fields in each of the stack locations.

Bug Check 0x45: INSUFFICIENT_SYSTEM_MAP_REGS

5/26/2017 • 1 min to read • [Edit Online](#)

The INSUFFICIENT_SYSTEM_MAP_REGS bug check has a value of 0x00000045.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x46: DEREF_UNKNOWN_LOGON_SESSION

5/26/2017 • 1 min to read • [Edit Online](#)

The DEREF_UNKNOWN_LOGON_SESSION bug check has a value of 0x00000046.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x47: REF_UNKNOWN_LOGON_SESSION

5/26/2017 • 1 min to read • [Edit Online](#)

The REF_UNKNOWN_LOGON_SESSION bug check has a value of 0x00000047.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x48: CANCEL_STATE_IN_COMPLETED_IRP

5/26/2017 • 1 min to read • [Edit Online](#)

The CANCEL_STATE_IN_COMPLETED_IRP bug check has a value of 0x00000048. This indicates that an I/O request packet (IRP) was completed, and then was subsequently canceled.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CANCEL_STATE_IN_COMPLETED_IRP Parameters

PARAMETER	DESCRIPTION
1	A pointer to the IRP
2	The cancel routine set by the driver
3	Reserved
4	Reserved

Cause

An IRP that had a *Cancel* routine set was completed normally, without cancellation. But after it was complete, a driver called the IRP's *Cancel* routine.

This could be caused by a driver that completed the IRP and then attempted to cancel it.

It could also be caused by two drivers each trying to access the same IRP in an improper way.

Resolution

The cancel routine parameter can be used to determine which driver or stack caused the bug check.

Bug Check 0x49: PAGE_FAULT_WITH_INTERRUPTS_OFF

5/26/2017 • 1 min to read • [Edit Online](#)

The PAGE_FAULT_WITH_INTERRUPTS_OFF bug check has a value of 0x00000049.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x4A: IRQL_GT_ZERO_AT_SYSTEM_SERVICE

5/26/2017 • 1 min to read • [Edit Online](#)

The IRQL_GT_ZERO_AT_SYSTEM_SERVICE bug check has a value of 0x0000004A. This indicates that a thread is returning to user mode from a system call when its IRQL is still above PASSIVE_LEVEL.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

IRQL_GT_ZERO_AT_SYSTEM_SERVICE Parameters

PARAMETER	DESCRIPTION
1	The address of the system function (system call routine)
2	The current IRQL
3	0
4	0

Bug Check 0x4B: STREAMS_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The STREAMS_INTERNAL_ERROR bug check has a value of 0x0000004B.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x4C: FATAL_UNHANDLED_HARD_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The FATAL_UNHANDLED_HARD_ERROR bug check has a value of 0x0000004C.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x4D: NO_PAGES_AVAILABLE

5/26/2017 • 2 min to read • [Edit Online](#)

The NO_PAGES_AVAILABLE bug check has a value of 0x0000004D. This indicates that no free pages are available to continue operations.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NO_PAGES_AVAILABLE Parameters

PARAMETER	DESCRIPTION
1	The total number of dirty pages
2	The number of dirty pages destined for the page file
3	Windows XP and Windows 2000: The size of the nonpaged pool available at the time the bug check occurred Windows Server 2003 and later: Reserved
4	Windows 2000: The number of transition pages that are currently stranded Windows XP and later: The most recent modified write error status.

Cause

To see general memory statistics, use the [!vm 3](#) extension.

This bug check can occur for any of the following reasons:

- A driver has blocked, deadlocking the modified or mapped page writers. Examples of this include mutex deadlocks or accesses to paged out memory in file system drivers or filter drivers. This indicates a driver bug.

If Parameter 1 or Parameter 2 is large, then this is a possibility. Use [!vm 3](#).

- A storage driver is not processing requests. Examples of this are stranded queues and non-responding drives. This indicates a driver bug.

If Parameter 1 or Parameter 2 is large, then this is a possibility. Use [!vm 8](#), followed by [!process 0 7](#).

- A high-priority realtime thread has starved the balance set manager from trimming pages from the working set, or starved the modified page writer from writing them out. This indicates a bug in the component that created this thread.

This situation is difficult to analyze. Try using [!ready](#). Try also [!process 0 7](#) to list all threads and see if any

have accumulated excessive kernel time as well as what their current priorities are. Such processes may have blocked out the memory management threads from making pages available.

- **Windows XP and Windows 2000:** Not enough pool is available for the storage stack to write out modified pages. This indicates a driver bug.

If Parameter 3 is small, then this is a possibility. Use **`!vm`** and **`!poolused 2`**.

- **Windows 2000:** All the processes have been trimmed to their minimums and all modified pages written, but still no memory is available. The freed memory must be stuck in transition pages with non-zero reference counts -- thus they cannot be put on the freelist.

A driver is neglecting to unlock the pages preventing the reference counts from going to zero which would free the pages. This may be due to transfers that never finish, causing the driver routines to run endlessly, or to other driver bugs.

If Parameter 4 is large, then this is a possibility. But it is very hard to find the driver. Try the **`!process 0 1`** extension and look for any drivers that have a lot of locked pages.

If the problem cannot be found, then try booting with a kernel debugger attached from the beginning, and monitor the situation.

Bug Check 0x4E: PFN_LIST_CORRUPT

5/26/2017 • 1 min to read • [Edit Online](#)

The PFN_LIST_CORRUPT bug check has a value of 0x0000004E. This indicates that the page frame number (PFN) list is corrupted.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PFN_LIST_CORRUPT Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of *Parameter 1*.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x01	The ListHead value that was corrupted	The number of pages available	0	The list head was corrupted.
0x02	The entry in the list that is being removed	The highest physical page number	The reference count of the entry being removed	A list entry was corrupted.
0x07	The page frame number	The current share count	0	A driver has unlocked a certain page more times than it locked it.
0x8D	The page frame number whose state is inconsistent	0	0	The page-free list is corrupted. This error code most likely indicates a hardware issue.
0x8F	New page number	Old page number	0	The free or zeroed page listhead is corrupted.
0x99	Page frame number	Current page state	0	A page table entry (PTE) or PFN is corrupted.
0x9A	Page frame number	Current page state	The reference count of the entry that is being removed	A driver attempted to free a page that is still locked for IO.

Cause

This error is typically caused by a driver passing a bad memory descriptor list. For example, the driver might have called **MmUnlockPages** twice with the same list.

If a kernel debugger is available, examine the stack trace.

Bug Check 0x4F: NDIS_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The NDIS_INTERNAL_ERROR bug check has a value of 0x0000004F.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x50: PAGE_FAULT_IN_NONPAGED_AREA

5/26/2017 • 2 min to read • [Edit Online](#)

The PAGE_FAULT_IN_NONPAGED_AREA bug check has a value of 0x00000050. This indicates that invalid system memory has been referenced. Typically the memory address is wrong or the memory address is pointing at freed memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PAGE_FAULT_IN_NONPAGED_AREA Parameters

PARAMETER	DESCRIPTION
1	Memory address referenced
2	0: Read operation 1: Write operation
3	Address that referenced memory (if known)
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

Bug check 0x50 can occur after the installation of faulty hardware or in the event of failure of installed hardware (usually related to defective RAM, be it main memory, L2 RAM cache, or video RAM).

Another possible cause is the installation of a faulty system service or faulty driver code.

Antivirus software can also trigger this error, as can a corrupted NTFS volume.

Resolution

Gather Information

Examine the name of the driver if that was listed on the blue screen.

Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.

Windows Memory Diagnostics

Run the Windows Memory Diagnostics tool, to test the memory. Click the Start button, and then clicking Control Panel. In the search box, type Memory, and then click **Diagnose your computer's memory problems**. After the

test is run, use Event viewer to view the results under the System log. Look for the *MemoryDiagnostics-Results* entry to view the results.

Resolving a faulty hardware problem: If hardware has been added to the system recently, remove it to see if the error recurs. If existing hardware has failed, remove or replace the faulty component. You should run hardware diagnostics supplied by the system manufacturer. For details on these procedures, see the owner's manual for your computer.

Resolving a faulty system service problem: Disable the service and confirm that this resolves the error. If so, contact the manufacturer of the system service about a possible update. If the error occurs during system startup, investigate the Windows repair options. For more information, see [Recovery options in Windows 10](#).

Resolving an antivirus software problem: Disable the program and confirm that this resolves the error. If it does, contact the manufacturer of the program about a possible update.

Resolving a corrupted NTFS volume problem: Run **Chkdsk /f /r** to detect and repair disk errors. You must restart the system before the disk scan begins on a system partition. Contact the manufacturer of the hard driver system to locate any diagnostic tools that they provide for the hard drive sub system.

For general blue screen troubleshooting information, see [Blue Screen Data](#).

Remarks

Typically, this address is in freed memory or is simply invalid.

This cannot be protected by a **try - except** handler -- it can only be protected by a probe.

Bug Check 0x51: REGISTRY_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The REGISTRY_ERROR bug check has a value of 0x00000051. This indicates that a severe registry error has occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

REGISTRY_ERROR Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	The pointer to the hive (if available)
4	If the hive is corrupt, the return code of HvCheckHive (if available)

Cause

Something has gone wrong with the registry. If a kernel debugger is available, get a stack trace.

This error may indicate that the registry encountered an I/O error while trying to read one of its files. This can be caused by hardware problems or file system corruption.

It may also occur due to a failure in a refresh operation, which is used only in by the security system, and then only when resource limits are encountered.

Bug Check 0x52: MAILSLOT_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The MAILSLOT_FILE_SYSTEM bug check has a value of 0x00000052.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x53: NO_BOOT_DEVICE

5/26/2017 • 1 min to read • [Edit Online](#)

The NO_BOOT_DEVICE bug check has a value of 0x00000053.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x54: LM_SERVER_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The LM_SERVER_INTERNAL_ERROR bug check has a value of 0x00000054.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x55: DATA_COHERENCY_EXCEPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The DATA_COHERENCY_EXCEPTION bug check has a value of 0x00000055.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x56: INSTRUCTION_COHERENCY_EXCEPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The INSTRUCTION_COHERENCY_EXCEPTION bug check has a value of 0x00000056.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x57: XNS_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The XNS_INTERNAL_ERROR bug check has a value of 0x00000057.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x58: FTDISK_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The FTDISK_INTERNAL_ERROR bug check has a value of 0x00000058. This is issued if the system is booted from the wrong copy of a mirrored partition.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

FTDISK_INTERNAL_ERROR Parameters

None

Cause

The hives are indicating that the mirror is valid, but it is not. The hives should actually be pointing to the shadow partition.

This is almost always caused by the primary partition being revived.

Resolution

Reboot the system from the shadow partition.

Bug Check 0x59: PINBALL_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The PINBALL_FILE_SYSTEM bug check has a value of 0x00000059. This indicates that a problem occurred in the Pinball file system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PINBALL_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	Reserved
3	Reserved
4	Reserved

Cause

One possible cause of this bug check is depletion of nonpaged pool memory. If the nonpaged pool memory is completely depleted, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver requiring nonpaged pool memory can also trigger this error.

Resolution

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This will increase the quantity of nonpaged pool memory available to the kernel.

Bug Check 0x5A: CRITICAL_SERVICE_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The CRITICAL_SERVICE_FAILED bug check has a value of 0x0000005A.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x5B: SET_ENV_VAR_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SET_ENV_VAR_FAILED bug check has a value of 0x0000005B.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x5C: HAL_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The HAL_INITIALIZATION_FAILED bug check has a value of 0x0000005C.

This indicates that the HAL initialization failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x5D: UNSUPPORTED_PROCESSOR

5/26/2017 • 1 min to read • [Edit Online](#)

The UNSUPPORTED_PROCESSOR bug check has a value of 0x0000005D. This indicates that the computer is attempting to run Windows on an unsupported processor.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UNSupported_Processor Parameters

None

Cause

Windows requires a higher-grade processor than the one you are using.

Bug Check 0x5E: OBJECT_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The OBJECT_INITIALIZATION_FAILED bug check has a value of 0x0000005E.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x5F: SECURITY_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SECURITY_INITIALIZATION_FAILED bug check has a value of 0x0000005F.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x60: PROCESS_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The PROCESS_INITIALIZATION_FAILED bug check has a value of 0x00000060.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x61: HAL1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The HAL1_INITIALIZATION_FAILED bug check has a value of 0x00000061.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x62: OBJECT1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The OBJECT1_INITIALIZATION_FAILED bug check has a value of 0x00000062.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x63: SECURITY1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SECURITY1_INITIALIZATION_FAILED bug check has a value of 0x00000063.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x64: SYMBOLIC_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SYMBOLIC_INITIALIZATION_FAILED bug check has a value of 0x00000064.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x65: MEMORY1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The MEMORY1_INITIALIZATION_FAILED bug check has a value of 0x00000065.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x66: CACHE_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The CACHE_INITIALIZATION_FAILED bug check has a value of 0x00000066.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x67: CONFIG_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The CONFIG_INITIALIZATION_FAILED bug check has a value of 0x00000067. This bug check indicates that the registry configuration failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CONFIG_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	The location selector
3	The NT status code
4	Reserved

Cause

The registry could not allocate the pool that it needed to contain the registry files. This situation should never occur, because the register allocates this pool early enough in system initialization so that plenty of paged pool should be available.

Bug Check 0x68: FILE_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The FILE_INITIALIZATION_FAILED bug check has a value of 0x00000068.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x69: IO1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The IO1_INITIALIZATION_FAILED bug check has a value of 0x00000069. This bug check indicates that the initialization of the I/O system failed for some reason.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

IO1_INITIALIZATION_FAILED Parameters

None

Cause

There is very little information available to analyze this error.

Most likely, the setup routine has improperly installed the system, or a user has reconfigured the system.

Bug Check 0x6A: LPC_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The LPC_INITIALIZATION_FAILED bug check has a value of 0x0000006A.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x6B: PROCESS1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The PROCESS1_INITIALIZATION_FAILED bug check has a value of 0x0000006B. This bug check indicates that the initialization of the Microsoft Windows operating system failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PROCESS1_INITIALIZATION_FAILED Parameters

The following parameters appear on the blue screen.

PARAMETER	DESCRIPTION
1	The NT status code that caused the failure
2	Reserved
3	Reserved
4	Reserved

Cause

Any part of the disk subsystem can cause the PROCESS1_INITIALIZATION_FAILED bug check, including bad disks, bad or incorrect cables, mixing different ATA-type devices on the same chain, or drives that are not available because of hardware regeneration.

This bug check can also be caused by a missing file from the boot partition or by a driver file that a user accidentally disabled in the **Drivers** tab.

Bug Check 0x6C: REFMON_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The REFMON_INITIALIZATION_FAILED bug check has a value of 0x0000006C.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x6D: SESSION1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION1_INITIALIZATION_FAILED bug check has a value of 0x0000006D. This bug check indicates that the initialization of the Microsoft Windows operating system failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION1_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	The NT status code that caused the initialization failure
2	0
3	0
4	0

Bug Check 0x6E: SESSION2_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION2_INITIALIZATION_FAILED bug check has a value of 0x0000006E. This bug check indicates that the initialization of the Microsoft Windows operating system failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION2_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	The NT status code that caused the Windows operating system to conclude that initialization failed
2	0
3	0
4	0

Bug Check 0x6F: SESSION3_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION3_INITIALIZATION_FAILED bug check has a value of 0x0000006F. This bug check indicates that the initialization of the Microsoft Windows operating system failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION3_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	The NT status code that caused the Windows operating system to conclude that initialization failed
2	0
3	0
4	0

Bug Check 0x70: SESSION4_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION4_INITIALIZATION_FAILED bug check has a value of 0x00000070. This bug check indicates that the initialization of the Microsoft Windows operating system failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION4_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	The NT status code that caused the Windows operating system to conclude that initialization failed
2	0
3	0
4	0

Bug Check 0x71: SESSION5_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION5_INITIALIZATION_FAILED bug check has a value of 0x00000071. This bug check indicates that the initialization of the Microsoft Windows operating system failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION5_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	The NT status code that caused the Windows operating system to conclude that initialization failed
2	0
3	0
4	0

Bug Check 0x72: ASSIGN_DRIVE LETTERS FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The ASSIGN_DRIVE LETTERS FAILED bug check has a value of 0x00000072.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x73: CONFIG_LIST_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The CONFIG_LIST_FAILED bug check has a value of 0x00000073. This bug check indicates that one of the top-level registry keys, also known as core system hives, cannot be linked in the registry tree.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CONFIG_LIST_FAILED Parameters

PARAMETER	DESCRIPTION
1	1
2	The NT status code that led the Windows operating system to assume that it failed to load the hive
3	The index of the hive in the hive list
4	A pointer to a UNICODE_STRING structure that contains the file name of the hive

Cause

The registry hive that cannot be linked might be SAM, SECURITY, SOFTWARE, or DEFAULT. The hive is valid, because it was loaded successfully.

Examine Parameter 2 to see why the hive could not be linked in the registry tree. One common cause of this error is that the Windows operating system is out of disk space on the system drive. (In this situation, this parameter is 0xC000017D, STATUS_NO_LOG_SPACE.) Another common problem is that an attempt to allocate pool has failed. (In this situation, Parameter 2 is 0xC000009A, STATUS_INSUFFICIENT_RESOURCES.) You must investigate other status codes.

Bug Check 0x74: BAD_SYSTEM_CONFIG_INFO

5/26/2017 • 1 min to read • [Edit Online](#)

The BAD_SYSTEM_CONFIG_INFO bug check has a value of 0x00000074. This bug check indicates that there is an error in the registry.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BAD_SYSTEM_CONFIG_INFO Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	The NT status code (if it is available)

Cause

The BAD_SYSTEM_CONFIG_INFO bug check occurs if the SYSTEM hive is corrupt. However, this corruption is unlikely, because the boot loader, checks a hive for corruption when it loads the hive.

This bug check can also occur if some critical registry keys and values are missing. The keys and values might be missing if a user manually edited the registry or if an application or service corrupted the registry.

Resolution

Try booting into safe mode and then restart the OS normally. If the restart does not fix the problem, the registry damage is too extensive. Try the following steps.

- If you have a system restore point, try restoring to an earlier restore point.
- Reset your PC.
- Use installation media to restore or reset your PC.
- Use installation media to reinstall Windows.

For more information, see [Recovery options in Windows 10](#).

Bug Check 0x75: CANNOT_WRITE_CONFIGURATION

5/26/2017 • 1 min to read • [Edit Online](#)

The CANNOT_WRITE_CONFIGURATION bug check has a value of 0x00000075. This bug check indicates that the SYSTEM registry hive file cannot be converted to a mapped file.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CANNOT_WRITE_CONFIGURATION Parameters

PARAMETER	DESCRIPTION
1	1
2	The NT status code that led the Windows operating system to assume that it had failed to convert the hive
3	Reserved
4	Reserved

Cause

The CANNOT_WRITE_CONFIGURATION bug check typically occurs if the system is out of pool and the Windows operating system cannot reopen the hive.

This bug check should almost never occur, because the conversion of the hive file occurs early enough during system initialization so that enough pool should be available.

Bug Check 0x76: PROCESS_HAS_LOCKED_PAGES

5/26/2017 • 2 min to read • [Edit Online](#)

The PROCESS_HAS_LOCKED_PAGES bug check has a value of 0x00000076. This bug check indicates that a driver failed to release locked pages after an I/O operation, or that it attempted to unlock pages that were already unlocked.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PROCESS_HAS_LOCKED_PAGES Parameters

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x00	The pointer to the process object	The number of locked pages	The pointer to driver stacks (if they are enabled). Otherwise, this parameter is zero.	The process being terminated has locked memory pages. The driver must unlock any memory that it might have locked in a process, before the process terminates.
0x01	MDL specified by the driver	Current number of locked memory pages in that process	A pointer to driver stacks for that process (if they are enabled). Otherwise, this parameter is zero.	The driver is attempting to unlock process memory pages that are not locked.

Cause

The driver either failed to unlock pages that it locked (parameter 1 value is 0x0), or the driver is attempting to unlock pages that have not been locked or that have already been unlocked (parameter 1 value is 0x1).

Resolution

If the parameter 1 value is 0x0

First use the **!search** extension on the current process pointer throughout all of physical memory. This extension might find at least one memory descriptor list (MDL) that points to the current process. Next, use **!search** on each MDL that you find to obtain the I/O request packet (IRP) that points to the current process. From this IRP, you can identify which driver is leaking the pages.

Otherwise, you can detect which driver caused the error by editing the registry:

1. In the **\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management** registry key, create or edit the **TrackLockedPages** value, and then set it equal to DWORD 1.

2. Restart the computer.

The system then saves stack traces, so you can easily identify the driver that caused the problem. If the driver causes the same error again, **bug check 0xCB** (DRIVER_LEFT_LOCKED_PAGES_IN_PROCESS) is issued, and the name of the driver that causes this error is displayed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

If the parameter 1 value is 0x1

Examine the driver source code that locks and unlocks memory, and try to locate an instance where memory is unlocked without first being locked.

Bug Check 0x77: KERNEL_STACK_INPAGE_ERROR

5/26/2017 • 4 min to read • [Edit Online](#)

The KERNEL_STACK_INPAGE_ERROR bug check has a value of 0x00000077. This bug check indicates that the requested page of kernel data from the paging file could not be read into memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_STACK_INPAGE_ERROR Parameters

The four parameters that listed in the message have two possible meanings.

If the first parameter is 0, 1, or 2, the parameters have the following meaning.

PARAMETER	DESCRIPTION
1	0: The page of kernel data was retrieved from page cache. 1: The page was retrieved from a disk. 2: The page was retrieved from a disk, the storage stack returned SUCCESS, but Status.Information is not equal to PAGE_SIZE.
2	The value that appears in the stack where the signature should be.
3	0
4	The address of the signature on the kernel stack

If the first parameter is any value other than 0, 1, or 2, the parameters have the following meaning.

PARAMETER	DESCRIPTION
1	The status code
2	The I/O status code
3	The page file number
4	The offset into page file

Cause

If the first parameter is 0 or 1, the stack signature in the kernel stack was not found. This error is probably caused

by defective hardware, such as a RAM error.

If the first parameter is 2, the driver stack returned an inconsistent status for the read of the page. For example, the driver stack returned a success status even though it did not read the whole page.

If the first parameter is any value other than 0, 1, or 2, the value of the first parameter is an NTSTATUS error code that the driver stack returns after it tries to retrieve the page of kernel data. You can determine the exact cause of this error from the I/O status code (the second parameter). Some common status codes include the following:

- 0xC000009A, or STATUS_INSUFFICIENT_RESOURCES, indicates a lack of nonpaged pool resources. This status code indicates a driver error in the storage stack. (The storage stack should always be able to retrieve this data, regardless of software resource availability.)
- 0xC000009C, or STATUS_DEVICE_DATA_ERROR, indicates bad blocks (sectors) on the hard disk.
- 0xC000009D, or STATUS_DEVICE_NOT_CONNECTED, indicates defective or loose cabling, termination, or that the controller does not see the hard disk drive.
- 0xC000016A, or STATUS_DISK_OPERATION_FAILED, indicates bad blocks (sectors) on the hard disk.
- 0xC0000185, or STATUS_IO_DEVICE_ERROR, indicates improper termination or defective cabling on SCSI devices or that two devices are trying to use the same IRQ.

These status codes are the most common ones that have specific causes. For more information about other possible status codes that might be returned, see the Ntstatus.h file in the Microsoft Windows Driver Kit (WDK).

A virus infection can also cause this bug check.

Resolution

Resolving a bad block problem: If you can restart the computer after the error, Autochk runs automatically and attempts to map the bad sector to prevent it from being used anymore.

If Autochk does not scan the hard disk for errors, you can manually start the disk scanner. Run **Chkdsk /f /r** on the system partition. You must restart the computer before the disk scan begins. If you cannot start the system because the error, use the Recovery Console and run **Chkdsk /r**.

Warning If your system partition is formatted with the FAT file system, the long file names that the Windows operating system uses might be damaged if you use Scandisk or another MS-DOS-based hard disk tool to verify the integrity of your hard disk drive from MS-DOS. Always use the version of Chkdsk that matches your version of the Windows operating system.

Resolving a defective hardware problem: If the I/O status is 0xC0000185 and the paging file is on an SCSI disk, check the disk cabling and SCSI termination for problems.

Resolving a failing RAM problem: Run the hardware diagnostics that the system manufacturer supplies, especially the memory scanner. For more information about these procedures, see the owner's manual for your computer.

Check that all the adapter cards in the computer are properly seated. Use an ink eraser or an electrical contact treatment, available at electronics supply stores, to ensure adapter card contacts are clean.

Check the System Log in Event Viewer for additional error messages that might help identify the device that is causing the error. You can also disable memory caching of the BIOS to try to resolve this error.

Make sure that the latest Windows Service Pack is installed.

If the preceding steps fail to resolve the error, take the system motherboard to a repair facility for diagnostic testing. A crack, a scratched trace, or a defective component on the motherboard can cause this error.

Resolving a virus infection: Check your computer for viruses by using any up-to-date, commercial virus scanning software that examines the Master Boot Record of the hard disk. All Windows file systems can be infected by viruses.

See also

[Bug Check 0x7A \(KERNEL_DATA_INPAGE_ERROR\)](#)

Bug Check 0x78: PHASE0_EXCEPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The PHASE0_EXCEPTION bug check has a value of 0x00000078.

This bug check occurs when an unexpected break is encountered during HAL initialization. This break can occur if you have set the **/break** parameter in your boot settings but have not enabled kernel debugging.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x79: MISMATCHED_HAL

5/26/2017 • 2 min to read • [Edit Online](#)

The MISMATCHED_HAL bug check has a value of 0x00000079. This bug check indicates that the Hardware Abstraction Layer (HAL) revision level or configuration does not match that of the kernel or the computer.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MISMATCHED_HAL Parameters

Parameter 1 indicates the type of mismatch.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE.
0x1	The major processor control block (PRCB) level of Ntoskrnl.exe.	The major PRCB level of Hal.dll.	Reserved	The PRCB release levels are mismatched. (Something is out of date.)
0x2	The build type of Ntoskrnl.exe.	The build type of Hal.dll.	Reserved	The build types are mismatched.
0x3	The size of the loader parameter extension.	The major version of the loader parameter extension.	The minor version of the loader parameter extension.	The loader (ntldr) and HAL versions are mismatched.

When Parameter 1 equals 0x2, the following build type codes are used:

- 0: Multiprocessor-enabled free build
- 1: Multiprocessor-enabled checked build
- 2: Single-processor free build
- 3: Single-processor checked build

Cause

The MISMATCHED_HAL bug check often occurs when a user manually updates Ntoskrnl.exe or Hal.dll.

The error can also indicate that one of those two files is out of date. For example, the HAL might be designed for Microsoft Windows 2000 and the kernel is designed for Windows XP. Or the computer might erroneously have a multiprocessor HAL and a single-processor kernel installed, or vice versa.

The Ntoskrnl.exe kernel file is for single-processor systems and Ntkrnlmp.exe is for multiprocessor systems. However, these file names correspond to the files on the installation media. After you have installed the Windows operating system, the file is renamed to Ntoskrnl.exe, regardless of the source file that is used. The HAL file also uses the name Hal.dll after installation, but there are several possible HAL files on the installation media. For more information, see "Installing the Checked Build" in the Windows Driver Kit (WDK).

Resolution

Restart the computer by using the product CD or the Windows Setup disks. At the Welcome screen, press F10 to start the Recovery Console. Use the **Copy** command to copy the correct HAL or kernel file from the original CD into the appropriate folder on the hard disk. The **Copy** command detects whether the file that you are copying is in the Microsoft compressed file format. If so, it automatically expands the file that is copied on the target drive.

Bug Check 0x7A: KERNEL_DATA_INPAGE_ERROR

5/26/2017 • 4 min to read • [Edit Online](#)

The KERNEL_DATA_INPAGE_ERROR bug check has a value of 0x0000007A. This bug check indicates that the requested page of kernel data from the paging file could not be read into memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_DATA_INPAGE_ERROR Parameters

The four parameters that are listed in the message can have three possible meanings. If the first parameter is 1 or 2, or 3 and the third parameter is 0, the parameters have the following definitions.

PARAMETER	DESCRIPTION
1	The lock type that was held (1, 2, or 3)
2	The error status (usually an I/O status code)
3	If Lock Type is 1: the current process If Lock Type is 2 or 3: 0
4	The virtual address that could not be paged into memory

If the first parameter is 3 (and the third parameter is nonzero) or 4, the parameters have the following definitions.

PARAMETER	DESCRIPTION
1	The lock type that was held (3 or 4)
2	The error status (typically an I/O status code)
3	The address of the InPageSupport structure
4	The faulting address

Otherwise, the parameters have the following definitions.

PARAMETER	DESCRIPTION
1	The address of the page table entry (PTE)

PARAMETER	DESCRIPTION
2	The error status (usually an I/O status code)
3	The PTE contents
4	The faulting address

Cause

Frequently, you can determine the cause of the KERNEL_DATA_INPAGE_ERROR bug check from the error status (Parameter 2). Some common status codes include the following:

- 0xC000009A, or STATUS_INSUFFICIENT_RESOURCES, indicates a lack of nonpaged pool resources.
- 0xC000009C, or STATUS_DEVICE_DATA_ERROR, typically indicates bad blocks (sectors) on the hard disk.
- 0xC000009D, or STATUS_DEVICE_NOT_CONNECTED, indicates defective or loose cabling, termination, or that the controller does not see the hard disk.
- 0xC000016A, or STATUS_DISK_OPERATION_FAILED, indicates bad blocks (sectors) on the hard disk.
- 0xC0000185, or STATUS_IO_DEVICE_ERROR, indicates improper termination or defective cabling on SCSI devices or that two devices are trying to use the same IRQ.
- 0xC000000E, or STATUS_NO_SUCH_DEVICE, indicates a hardware failure or an incorrect drive configuration. Check your cables and check the drive with the diagnostic utility available from your drive manufacturer. If you are using older PATA (IDE) drives, this status code can indicate an incorrect master/subordinate drive configuration.

These status codes are the most common ones that have specific causes. For more information about other possible status codes that can be returned, see the Ntstatus.h file in the Microsoft Windows Driver Kit (WDK).

Another common cause of this error message is defective hardware or failing RAM.

A virus infection can also cause this bug check.

Resolution

Resolving a bad block problem: An I/O status code of 0xC000009C or 0xC000016A typically indicates that the data could not be read from the disk because of a bad block (sector). If you can restart the computer after the error, Autochk runs automatically and attempts to map the bad sector to prevent it from being used anymore.

If Autochk does not scan the hard disk for errors, you can manually start the disk scanner. Run **Chkdsk /f /r** on the system partition. You must restart the computer before the disk scan begins. If you cannot start the computer because of the error, use the Recovery Console and run **Chkdsk /r**.

Warning If your system partition is formatted with the FAT file system, the long file names that the Windows operating system uses might be damaged if you use Scandisk or another MS-DOS-based hard disk tool to verify the integrity of your hard disk from MS-DOS. Always use the version of Chkdsk that matches your version of Windows.

Resolving a defective hardware problem: If the I/O status is C0000185 and the paging file is on an SCSI disk, check the disk cabling and SCSI termination for problems.

Resolving a failing RAM problem: Run the hardware diagnostics that the system manufacturer supplies, especially the memory scanner. For more information about these procedures, see the owner's manual for your computer.

Check that all the adapter cards in the computer are properly seated. Use an ink eraser or an electrical contact treatment, available at electronics supply stores, to ensure adapter card contacts are clean.

Check the System Log in Event Viewer for additional error messages that might help identify the device that is causing the error. You can also disable memory caching of the BIOS to try to resolve this error.

Make sure that the latest Windows Service Pack is installed.

If the preceding steps do not resolve the error, take the system motherboard to a repair facility for diagnostic testing. A crack, a scratched trace, or a defective component on the motherboard can cause this error.

Resolving a virus infection: Check your computer for viruses by using any up-to-date, commercial virus scanning software that examines the Master Boot Record of the hard disk. All Windows file systems can be infected by viruses.

Bug Check 0x7B: INACCESSIBLE_BOOT_DEVICE

5/26/2017 • 9 min to read • [Edit Online](#)

The INACCESSIBLE_BOOT_DEVICE bug check has a value of 0x0000007B. This bug check indicates that the Microsoft Windows operating system has lost access to the system partition during startup.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INACCESSIBLE_BOOT_DEVICE Parameters

PARAMETER	DESCRIPTION
1	The address of a UNICODE_STRING structure, or the address of the device object that could not be mounted
2	0
3	0
4	0

To determine the meaning of Parameter 1, look at the data that it points to. If the first word (USHORT) at this address is even, Parameter 1 is the beginning of a Unicode string. If the first word (USHORT) at this address is 0x3, Parameter 1 is the first field (Type) of a device object.

- If this parameter points to a device object, the file system that was supposed to read the boot device failed to initialize or simply did not recognize the data on the boot device as a file system structure. In this situation, the specified device object is the object that could not be mounted.
- If this parameter points to a Unicode string, you must read the first 8 bytes at this address. These bytes form the UNICODE_STRING structure, which is defined as follows:

```
USHORT Length;
USHORT MaximumLength;
PWSTR Buffer;
```

The **Length** field gives the actual length of the string. The **Buffer** field points to the beginning of the string (**Buffer** is always be at least 0x80000000.)

The actual string contains the Advanced RISC Computing (ARC) specification name of the device that the boot was being attempted from. ARC names are a generic way to identify devices in the ARC environment.

Cause

The INACCESSIBLE_BOOT_DEVICE bug check frequently occurs because of a boot device failure. During I/O system initialization, the boot device driver might have failed to initialize the boot device (typically a hard disk).

File system initialization might have failed because it did not recognize the data on the boot device. Also,

repartitioning the system partition, changing the BIOS configuration, or installing a disk controller might induce this error.

This error can also occur because of incompatible disk hardware. If the error occurred at the initial setup of the system, the system might have been installed on an unsupported disk controller. Some disk controllers require additional drivers to be present when Windows starts.

Resolution

This error always occurs while the system is starting. This error frequently occurs before the debugger connection is established, so debugging can be difficult. In addition, the OS may not be accessible and the error logs may be empty as the OS has not booted far enough to start those sub-systems.

If you are unable to boot Windows

If you receive this stop code and Windows doesn't boot forward into the OS, try the following:

Revert any recent hardware changes

Remove any recently added hardware, especially hard disk drives or controllers, to see if the error is resolved. If the problematic hardware is a hard disk drive, the disk firmware version might be incompatible with your version of the Windows operating system. Contact the manufacturer for updates. If you removed another piece of hardware and the error is resolved, IRQ or I/O port conflicts may exist. Reconfigure the new device according to the manufacturer's instructions.

If you have recently made changes to BIOS settings, such as changing the controller mode from legacy to AHCI in the BIOS, revert those changes. For more information, see

https://en.wikipedia.org/wiki/Advanced_Host_Controller_Interface

Check for storage device compatibility

Confirm that all hard disk drivers, hard disk controllers, and any other storage adapters are compatible with the installed version of Windows. For example, you can get information about compatibility at [Windows 10 Specifications](#).

Update BIOS and Firmware

Check the availability of updates for the system BIOS and storage controller firmware.

Use the Media Creation Tool to create a bootable USB thumb drive or DVD

Use Media Creation Tool, using another computer to create a bootable USB thumb drive or DVD. Use it to perform a clean install, by clicking on the setup file or booting from the USB.

For more information, see [Get Windows 10](#).

Be aware that you may need to disable features, such as quick BIOS boot, or you may not be able to reach the boot device priority menu. Change your boot sequence priority in the BIOS menu to boot from FDD (FlashDiskDrive) or DVD instead of HDD.

Common Boot Menu Keys

The boot menu key varies per manufacturer, these keys are commonly used. Check the system documentation to determine what boot key is used.

F12 ESC F9 F10 F8 **Common BIOS Setup Keys**

The BIOS setup key varies per manufacturer, these keys are commonly used. Check the system documentation to determine what setup key is used.

ESC DEL F2 ******

If you can boot Windows

- **Boot to Safe Mode and then Boot Normally**

Complete the following steps to boot into Safe Mode. Booting into safe mode loads a core set of storage drivers that may allow for the storage system to be accessed once again.

To enter Safe Mode, use **Update and Security** in Settings. Select **Recovery->Advanced startup** to boot to maintenance mode. At the resulting menu, choose **Troubleshoot-> Advanced Options -> Startup**

Settings -> Restart. After Windows restarts to the **Startup Settings** screen, select option, 4, 5 or 6 to boot to Safe Mode.

Once Windows is loaded in Safe Mode, restart your PC to see if the proper storage drivers will be loaded and that the storage device is recognized.

Safe Mode may also be available by pressing a function key on boot, for example F8. Refer to information from the system manufacturer for specific startup options.

- Use the scan disk utility to confirm that there are no file system errors. Right click on the drive you want to scan and select **Properties**. Click on **Tools**. Click the **Check now** button.
- Run a virus detection program. Viruses can infect all types of hard disks formatted for Windows, and resulting disk corruption can generate system bug check codes. Make sure the virus detection program checks the Master Boot Record for infections.
- For IDE devices, define the onboard IDE port as Primary only. Also check each IDE device for the proper **master/subordinate/stand alone** setting. Try removing all IDE devices except for hard disks. Finally, check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing the error.
- Confirm that there is sufficient free space on the hard drive. The operating system and some applications require sufficient free space to create swap files and for other functions. Based on the system configuration, the exact requirement varies, but it is normally a good idea to have 10% to 15% free space available.
- Look in **Device Manager** to see if any devices are marked with the exclamation point (!). Review the events log displayed in driver properties for any faulting driver. Try updating the related driver.
- Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- Use the System File Checker tool to repair missing or corrupted system files. The System File Checker is a utility in Windows that allows users to scan for corruptions in Windows system files and restore corrupted files. Use the following command to run the System File Checker tool (SFC.exe).

```
SFC /scannow
```

For more information, see [Use the System File Checker tool to repair missing or corrupted system files](#).

- After automatic repair, on the Choose an option screen, select **Troubleshoot > Advanced options >**

System Restore. This option takes your PC back to an earlier point in time, called a system restore point. Restore points are generated when you install a new app, driver, update, or when you create a restore point manually. Choose a restore point before you experienced the error.

- Use the kernel debugger to attach to the system and further analyze the failure as described in remarks.

Remarks

Investigating the storage system configuration

It is helpful to know as much as possible about the boot device that Windows is installed on. For example, you can investigate the following items:

- Find out what type of controller the boot device is connected to (SATA, IDE, etc). If you can boot the system, you can use device manager to examine the controller and disk driver properties and see the associated driver file as well as error events.
- Indicate if other devices are attached to the same controller that the boot device is on (SSD, DVD, and so on).
- Note the file system that is used on the drive, typically NTFS.

To analyze this error using the kernel debugger: Run an [!m \(List Loaded Modules\)](#) command in the debugger to see which modules are loaded to attempt to isolate the specific driver. Verify that the following drivers were loaded.

disk

```
0: kd> !m m disk
Browse full module list
start           end           module name
fffff806`bd0b0000 fffff806`bd0cd000  disk      (deferred)
```

partmgr

```
0: kd> !m m partmgr
Browse full module list
start           end           module name
fffff806`bc5a0000 fffff806`bc5c1000  partmgr   (deferred)
```

NTFS

```
0: kd> !m m ntfs
Browse full module list
start           end           module name
fffff806`bd3f0000 fffff806`bd607000  NTFS      (deferred)
```

classpnp

```
0: kd> !m m classpnp
Browse full module list
start           end           module name
fffff806`bd0d0000 fffff806`bd131000  CLASSPNP  (deferred)
```

pci

```
0: kd> lm m pci
Browse full module list
start           end           module name
fffff806`bc440000 fffff806`bc494000  pci      (deferred)
```

Also make sure your controller drivers are loaded. For example for a SATA RAID Controller, this might be the *iaStorA.Sys* driver, or it could be the *EhStorClass* driver.

```
0: kd> lm m EhStorClass
Browse full module list
start           end           module name
fffff806`bcbb0000 fffff806`bcbbcb000  EhStorClass  (deferred)
```

List the drivers that contain "stor", storahci, may be present.

```
0: kd> lm m stor*
Browse full module list
start           end           module name
fffff806`bcb00000 fffff806`bcb23000  storahci  (deferred)
fffff806`bcb30000 fffff806`bcbaa000  storport   (deferred)
fffff806`c0770000 fffff806`c0788000  storqosfl  (deferred)
```

Booting with a debugger attached

If you can boot the target system with a debugger connected, issue **!devnode 0 1** when the bugcheck occurs. You'll see which device lacks a driver or could not start, and the reason for not starting may be apparent.

One cause, might be that Plug and Play cannot assign resources to the boot device. You can verify this restriction by finding an entry for the service. If the status flags include DNF_INSUFFICIENT_RESOURCES or do not include DNF_STARTED or DNF_ENUMERATED, you may have located the problem. Try **!devnode 0 1 storahci** to save some time, instead of dumping the whole device tree.

```
0: kd> !devnode 0 1 storahci
Dumping IopRootDeviceNode (= 0xfffffb9053d94d850)
DevNode 0xfffffb9053e8dea50 for PDO 0xfffffb9053e8da060
  InstancePath is "PCI\VEN_8086&DEV_3B22&SUBSYS_304A103C&REV_05\3&21436425&0&FA"
  ServiceName is "storahci"
  State = DeviceNodeStarted (0x308)
  Previous State = DeviceNodeEnumerateCompletion (0x30d)
  DevNode 0xfffffb9053e88db30 for PDO 0xfffffb9053e890060
    InstancePath is "SCSI\Disk&Ven_&Prod_ST3500418AS\4&23d99fa2&0&000000"
    ServiceName is "disk"
    State = DeviceNodeStarted (0x308)
    Previous State = DeviceNodeEnumerateCompletion (0x30d)
  DevNode 0xfffffb9053e88d850 for PDO 0xfffffb9053e88e060

```

Bug Check 0x7C: BUGCODE_NDIS_DRIVER

5/31/2017 • 13 min to read • [Edit Online](#)

The BUGCODE_NDIS_DRIVER bug check has a value of 0x0000007C. This bug check indicates that the operating system detected an error in a networking driver.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BUGCODE_NDIS_DRIVER Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1. If a Parameter's value is "0," that means it is not used.

PARAMETER 1	PARAMETER 1 VALUE AND CAUSE OF ERROR	PARAMETER 2	PARAMETER 3	PARAMETER 4
0x01	NDIS_BUGCHECK _ALLOCATE_SHA RED_MEM_HIGH_ IRQL A driver called NdisMAllocateSharedMemory at a raised IRQL.	The address of the specific miniport adapter block. Run !ndiskd.netadapter with this address for more information.	The length of the requested shared memory	The current IRQL
0x02	NDIS_BUGCHECK _SHARED_MEM_C ORRUPTION During a call to NdisMAllocateSharedMemory , NDIS detected that a previously-allocated shared memory page had been corrupted.	The address of the specific miniport adapter block. Run !ndiskd.netadapter with this address for more information.	The shared memory page that was corrupted	The address of a NDIS_WRAPPER_CONTEXT that keeps track of shared memory allocations by the driver
0x03	NDIS_BUGCHECK _FREE_INVALID_SHARED_MEM A miniport driver called NdisMFreeSharedMemory (Async) with a shared memory address that had already been freed.	The address of the specific miniport adapter block. Run !ndiskd.netadapter with this address for more information.	The page from which this shared memory was allocated	The virtual address of the shared memory

PARAMETER 1	PARAMETER 1 VALUE AND CAUSE OF ERROR	PARAMETER 2	PARAMETER 3	PARAMETER 4
0x04	<p>NDIS_BUGCHECK _UNLOAD_DRIVE R_INVALID PARA METER</p> <p>AddDevice was called with a driver that is not on the list of drivers that are registered with NDIS.</p> <p>Enabled only on special instrumented NDIS.</p>	The address of the NDIS_M_DRIVER_BLOCK	The address of the DRIVER_OBJECT	0
0x05	<p>NDIS_BUGCHECK _RECVD_PACKET_ IN_USE_BAD_STA CK_LOCATION</p> <p>An Ethernet driver indicated that it received a packet using a packet descriptor that was currently in use by the protocol stack.</p> <p>Caught by checking stack packet location.</p>	<p>The address of the specific miniport adapter block. Run !ndiskd.netadap ter with this address for more information.</p>	<p>The address of the packet descriptor used by the driver. Run !ndiskd.pkt with this address for more information.</p>	<p>The address of the packet array that contained this packet descriptor</p>
0x06	<p>NDIS_BUGCHECK _RECVD_PACKET_ IN_USE_BAD_REF_ COUNT</p> <p>An Ethernet driver indicated that it received a packet using a packet descriptor that was currently in use by the protocol stack.</p> <p>Caught by checking packet reference count.</p>	<p>The address of the specific miniport adapter block. Run !ndiskd.netadap ter with this address for more information.</p>	<p>The address of the packet descriptor used by the driver. Run !ndiskd.pkt with this address for more information.</p>	<p>The address of the packet array that contained this packet descriptor</p>

PARAMETER 1	PARAMETER 1 VALUE AND CAUSE OF ERROR	PARAMETER 2	PARAMETER 3	PARAMETER 4
0x07	An FDDI driver indicated that it received a packet by using a packet descriptor that was currently in use by the protocol stack. Caught by checking reference count.	The address of the specific miniport adapter block. Run !ndiskd.netadAPTER with this address for more information.	The address of the packet descriptor used by the driver. Run !ndiskd.pkt with this address for more information.	The address of the packet array that contained this packet descriptor
0x08	NDIS_BUGCHECK _HALT_WITHOUT _INTERRUPT_DER EGISTER A miniport driver did not deregister its interrupt during the halt process.	The address of the specific miniport adapter block. Run !ndiskd.netadAPTER with this address for more information.	The address of the NDIS_MINIPORT_INTERRUPT	0
0x09	NDIS_BUGCHECK _HALT_WITHOUT _CANCEL_TIMER A miniport driver stopped without successfully canceling all its timers.	The address of the specific miniport adapter block. Run !ndiskd.netadAPTER with this address for more information.	The address of the miniport driver's timer queue (NDIS_MINIPORT_TIMER)	0
0x0A	NDIS_BUGCHECK _DRIVER_UNLOA D_UNEXPECTED A miniport driver is getting unloaded prematurely.	The address of the NDIS_M_DRIVER_BLOCK	The address of the DRIVER_OBJECT	The reference count for the miniport driver
0x0B	NDIS_BUGCHECK _INIT_FAILED_WIT HOUT_INTERRUPT_DEREGISTER A miniport driver failed its initialization without deregistering its interrupt.	The address of the specific miniport adapter block. Run !ndiskd.netadAPTER with this address for more information.	The address of the NDIS_MINIPORT_INTERRUPT	0

PARAMETER 1	PARAMETER 1 VALUE AND CAUSE OF ERROR	PARAMETER 2	PARAMETER 3	PARAMETER 4
0x0C	<p>NDIS_BUGCHECK _INIT_FAILED_WITHOUT_CANCEL_TIMER</p> <p>A miniport driver failed its initialization without successfully canceling all its timers.</p>	<p>The address of the specific miniport adapter block. Possible values:</p> <ul style="list-style-type: none"> • 0x01 : The leak was detected by the NBL tracker. The driver that is currently deregistering or unbinding is the most likely cause. Look at the callstack of the bugcheck thread. Drivers must not unbind or deregister while they still hold active NBLs. 	0	0

Cause

Parameter 1 indicates the specific cause of the BUGCODE_NDIS_DRIVER bug check.

Remarks

The BUGCODE_NDIS_DRIVER bugcheck identifies problems in network drivers. Often, the problem is caused by a NDIS miniport driver. You can get a complete list of NDIS miniport drivers by using [!ndiskd.netadapter](#). You can get a bigger picture overview of the network stack with [!ndiskd.netreport](#).

This bug check code occurs only on Microsoft Windows Server 2003 and later versions of Windows. In Windows 2000 and Windows XP, the corresponding code is **bug check 0xD2** (BUGCODE_ID_DRIVER).

Bug Check 0x7D: INSTALL_MORE_MEMORY

5/26/2017 • 1 min to read • [Edit Online](#)

The INSTALL_MORE_MEMORY bug check has a value of 0x0000007D. This bug check indicates that there is not enough memory to start up the Microsoft Windows operating system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INSTALL_MORE_MEMORY Parameters

PARAMETER	DESCRIPTION
1	The number of physical pages that are found
2	The lowest physical page
3	The highest physical page
4	0

Cause

The Windows operating system does not have sufficient memory to complete the startup process.

Resolution

Install more memory.

(Developer Content) Bug Check 0x7E: SYSTEM_THREAD_EXCEPTION_NOT_HANDLED

5/26/2017 • 2 min to read • [Edit Online](#)

The SYSTEM_THREAD_EXCEPTION_NOT_HANDLED bug check has a value of 0x0000007E. This bug check indicates that a system thread generated an exception that the error handler did not catch.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SYSTEM_THREAD_EXCEPTION_NOT_HANDLED Parameters

PARAMETER	DESCRIPTION
1	The exception code that was not handled
2	The address where the exception occurred
3	The address of the exception record
4	The address of the context record

Cause

The SYSTEM_THREAD_EXCEPTION_NOT_HANDLED bug check is a common bug check. To interpret it, you must identify which exception was generated.

Common exception codes include the following:

- 0x80000002: STATUS_DATATYPE_MISALIGNMENT indicates an unaligned data reference was encountered.
- 0x80000003: STATUS_BREAKPOINT indicates a breakpoint or ASSERT was encountered when no kernel debugger was attached to the system.
- 0xC0000005: STATUS_ACCESS_VIOLATION indicates a memory access violation occurred.

For a complete list of exception codes, see the Ntstatus.h file that is located in the inc directory of the Microsoft Windows Driver Kit (WDK).

Resolution

If you are not equipped to use the Windows debugger to work on this problem, you should use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing bug check 0x7E.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for

driver updates.

- Check with your hardware vendor for any BIOS updates. Hardware issues, such as BIOS incompatibilities, memory conflicts, and IRQ conflicts can also generate this error.
- You can also disable memory caching/shadowing of the BIOS might to try to resolve the error. You should also run hardware diagnostics, that the system manufacturer supplies.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- For additional general troubleshooting information, see [Blue Screen Data](#).

If you plan to debug this problem, Parameter 2 (the exception address) should identify the driver or function that caused this problem.

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in determining the root cause.

If exception code 0x80000003 occurs, a hard-coded breakpoint or assertion was hit, but the system was started with the **/NODEBUG** switch. This problem should not occur frequently. If it occurs repeatedly, make sure that a kernel debugger is connected and the system is started with the **/DEBUG** switch.

If exception code 0x80000002 occurs, the trap frame supplies additional information.

If a driver is listed by name within the bug check message, disable or remove that driver. If the issue is narrowed down to a single driver, set breakpoints and single step in code to work to locate the failure and gain insight into events leading up to the crash.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

[Analyzing a Kernel-Mode Dump File with WinDbg](#)

[Using the !analyze Extension and !analyze](#)

Bug Check 0x7F: UNEXPECTED_KERNEL_MODE_TRAP

5/26/2017 • 5 min to read • [Edit Online](#)

The UNEXPECTED_KERNEL_MODE_TRAP bug check has a value of 0x0000007F. This bug check indicates that the Intel CPU generated a trap and the kernel failed to catch this trap.

This trap could be a *bound trap* (a trap the kernel is not permitted to catch) or a *double fault* (a fault that occurred while processing an earlier fault, which always results in a system failure).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UNEXPECTED_KERNEL_MODE_TRAP Parameters

The first parameter that appears on the blue screen specifies the trap number.

The most common trap codes include the following:

- 0x00000000, or Divide by Zero Error, indicates that a DIV instruction is executed and the divisor is zero. Memory corruption, other hardware problems, or software failures can cause this error.
- 0x00000004, or Overflow, occurs when the processor executes a call to an interrupt handler when the overflow (OF) flag is set.
- 0x00000005, or Bounds Check Fault, indicates that the processor, while executing a BOUND instruction, finds that the operand exceeds the specified limits. A BOUND instruction ensures that a signed array index is within a certain range.
- 0x00000006, or Invalid Opcode, indicates that the processor tries to execute an invalid instruction. This error typically occurs when the instruction pointer has become corrupted and is pointing to the wrong location. The most common cause of this error is hardware memory corruption.
- 0x00000008, or Double Fault, indicates that an exception occurs during a call to the handler for a prior exception. Typically, the two exceptions are handled serially. However, there are several exceptions that cannot be handled serially, and in this situation the processor signals a double fault. There are two common causes of a double fault:
 - A kernel stack overflow. This overflow occurs when a guard page is hit, and the kernel tries to push a trap frame. Because there is no stack left, a stack overflow results, causing the double fault. If you think this overview has occurred, use **!thread** to determine the stack limits, and then use **kb (Display Stack Backtrace)** with a large parameter (for example, **kb 100**) to display the full stack.
 - A hardware problem.

The less-common trap codes include the following:

- 0x00000001 -- A system-debugger call
- 0x00000003 -- A debugger breakpoint
- 0x00000007 -- A hardware coprocessor instruction with no coprocessor present
- 0x0000000A -- A corrupted Task State Segment

- 0x0000000B -- An access to a memory segment that was not present
- 0x0000000C -- An access to memory beyond the limits of a stack
- 0x0000000D -- An exception not covered by some other exception; a protection fault that pertains to access violations for applications

For other trap numbers, see an Intel architecture manual.

Cause

Bug check 0x7F typically occurs after you install a faulty or mismatched hardware (especially memory) or if installed hardware fails.

A double fault can occur when the kernel stack overflows. This overflow occurs if multiple drivers are attached to the same stack. For example, if two file system filter drivers are attached to the same stack and then the file system recurses back in, the stack overflows.

Resolution

Debugging: Always begin with the [!analyze](#) extension.

If this extension is not sufficient, use the [kv \(Display Stack Backtrace\)](#) debugger command.

- If **kv** shows a **taskGate**, use the [.tss \(Display Task State Segment\)](#) command on the part before the colon.
- If **kv** shows a trap frame, use the [.trap \(Display Trap Frame\)](#) command to format the frame.
- Otherwise, use the [.trap \(Display Trap Frame\)](#) command on the appropriate frame. (On x86-based platforms, this frame is associated with the procedure **NT!KiTrap**.)

After using one of these commands, use **kv** again to display the new stack.

Troubleshooting: If you recently added hardware to the computer, remove it to see if the error recurs. If existing hardware has failed, remove or replace the faulty component. Run hardware diagnostics that the system manufacturer supplies to determine which hardware component failed.

The memory scanner is especially important. Faulty or mismatched memory can cause this bug check. For more information about these procedures, see the owner's manual for your computer. Check that all adapter cards in the computer are properly seated. Use an ink eraser or an electrical contact treatment, available at electronics supply stores, to ensure adapter card contacts are clean.

If the error appears on a newly installed system, check the availability of updates for the BIOS, the SCSI controller, or network cards. These kind of updates are typically available on the Web site or BBS of the hardware manufacturer.

Confirm that all hard disk drives, hard disk controllers, and SCSI adapters are compatible with the installed version of Windows. For example, you can get information about compatibility with Windows 7 at the [Windows 7 Compatibility Center](#).

If the error occurred after the installation of a new or updated device driver, you should remove or replace the driver. If, under this circumstance, the error occurs during the startup sequence and the system partition is formatted with NTFS, you might be able to use Safe Mode to rename or delete the faulty driver. If the driver is used as part of the system startup process in Safe Mode, you have to start the computer by using the Recovery Console in order to access the file.

Also restart your computer, and then press F8 at the character-based menu that displays the operating system choices. At the **Advanced Options** menu, select the **Last Known Good Configuration** option. This option is most effective when you add only one driver or service at a time.

Overclocking (setting the CPU to run at speeds above the rated specification) can cause this error. If you have overclocked the computer that is experiencing the error, return the CPU to the default clock speed setting.

Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing the error. You can also disable memory caching of the BIOS to try to resolve the problem.

If you encountered this error while upgrading to a new version of the Windows operating system, the error might be caused by a device driver, a system service, a virus scanner, or a backup tool that is incompatible with the new version. If possible, remove all third-party device drivers and system services and disable any virus scanners before you upgrade. Contact the software manufacturer to obtain updates of these tools. Also make sure that you have installed the latest Windows Service Pack.

Finally, if all the above steps do not resolve the error, take the system motherboard to a repair facility for diagnostic testing. A crack, a scratched trace, or a defective component on the motherboard can also cause this error.

Bug Check 0x80: NMI_HARDWARE_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The NMI_HARDWARE_FAILURE bug check has a value of 0x00000080. This bug check indicates that a hardware malfunction has occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NMI_HARDWARE_FAILURE Parameters

None

Cause

A variety of hardware malfunctions can cause the NMI_HARDWARE_FAILURE bug check. The exact cause is difficult to determine.

Resolution

Remove any hardware or drivers that have been recently installed. Make sure that all memory modules are of the same type.

Bug Check 0x81: SPIN_LOCK_INIT_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The SPIN_LOCK_INIT_FAILURE bug check has a value of 0x00000081.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x82: DFS_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The DFS_FILE_SYSTEM bug check has a value of 0x00000082.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x85: SETUP_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The SETUP_FAILURE bug check has a value of 0x00000085. This bug check indicates that a fatal error occurred during setup.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SETUP_FAILURE Parameters

Parameter 1 indicates the type of violation. Parameter 4 is not used. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	CAUSE
0x0	0	0	<p>The OEM HAL font is not a valid .fon format file, so setup cannot display text.</p> <p>This cause indicates that Vgaxxx.fon on the boot floppy or CD is damaged.</p>
0x1	<p>The precise video initialization failure:</p> <p>0: NtCreateFile of \device\video0</p> <p>1: IOCTL_VIDEO_QUERY_NUM_AVAIL_MODES</p> <p>2: IOCTL_VIDEO_QUERY_AVAIL_MODES</p> <p>3: The desired video mode is not supported. This value indicates an internal setup error.</p> <p>4: IOCTL_VIDEO_SET_CUR_RENT_MODE (unable to set video mode)</p> <p>5: IOCTL_VIDEO_MAP_VID_EO_MEMORY</p> <p>6: IOCTL_VIDEO_LOAD_AND_SET_FONT</p>	The status code from the NT API call, if appropriate	<p>Video initialization failed.</p> <p>This failure might indicate that the disk that contains Vga.sys (or another video driver that is appropriate to the computer) is damaged or that the computer has video hardware that the Microsoft Windows operating system cannot communicate with.</p>

PARAMETER 1	PARAMETER 2	PARAMETER 3	CAUSE
0x2	0	0	Out of memory.
0x3	<p>The precise keyboard initialization failure:</p> <p>0:NtCreateFile of \device\KeyboardClass0 failed. (Setup did not find a keyboard connected to the computer.)</p> <p>1: Unable to load keyboard layout DLL. (Setup could not load the keyboard layout file. This failure indicates that the CD or floppy disk is missing a file, such as Kbdus.dll for the U.S. release or another layout DLL for localized releases.)</p>	0	<p>Keyboard initialization failed.</p> <p>This failure might indicate that the disk that contains the keyboard driver (I8042prt.sys or Kbdclass.sys) is damaged or that the computer has keyboard hardware that Windows cannot communicate with. This failure might also mean that the keyboard layout DLL could not be loaded.</p>
0x4	0	0	<p>Setup could not resolve the ARC device path name of the device that setup was started from.</p> <p>This error is an internal setup error.</p>
0x5	Reserved	Reserved	<p>Partitioning sanity check failed.</p> <p>This error indicates a bug in a disk driver.</p>

Bug Check 0x8B: MBR_CHECKSUM_MISMATCH

5/26/2017 • 1 min to read • [Edit Online](#)

The MBR_CHECKSUM_MISMATCH bug check has a value of 0x0000008B. This bug check indicates that a mismatch has occurred in the MBR checksum.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MBR_CHECKSUM_MISMATCH Parameters

PARAMETER	DESCRIPTION
1	The disk signature from MBR
2	The MBR checksum that the OS Loader calculates
3	The MBR checksum that the system calculates
4	Reserved

Cause

The MBR_CHECKSUM_MISMATCH bug check occurs during the boot process when the MBR checksum that the Microsoft Windows operating system calculates does not match the checksum that the loader passes in.

This error typically indicates a virus.

Resolution

There are many forms of viruses and not all can be detected. Typically, the newer viruses usually can be detected only by a virus scanner that has recently been upgraded. You should boot with a write-protected disk that contains a virus scanner and try to clean out the infection.

Bug Check 0x8E: KERNEL_MODE_EXCEPTION_NOT_HANDLED

5/26/2017 • 3 min to read • [Edit Online](#)

The KERNEL_MODE_EXCEPTION_NOT_HANDLED bug check has a value of 0x0000008E. This bug check indicates that a kernel-mode application generated an exception that the error handler did not catch.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_MODE_EXCEPTION_NOT_HANDLED Parameters

PARAMETER	DESCRIPTION
1	The exception code that was not handled
2	The address where the exception occurred
3	The trap frame
4	Reserved

Cause

The KERNEL_MODE_EXCEPTION_NOT_HANDLED bug check is a very common bug check. To interpret it, you must identify which exception was generated.

Common exception codes include the following:

- 0x80000002: STATUS_DATATYPE_MISALIGNMENT indicates that an unaligned data reference was encountered.
- 0x80000003: STATUS_BREAKPOINT indicates that a breakpoint or ASSERT was encountered when no kernel debugger was attached to the system.
- 0xC0000005: STATUS_ACCESS_VIOLATION indicates that a memory access violation occurred.

For a complete list of exception codes, see the Ntstatus.h file that is located in the inc directory of the Microsoft Windows Driver Kit (WDK).

Resolution

If you are not equipped to debug this problem, you should use some basic troubleshooting techniques:

- Make sure you have enough disk space.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.

- Try changing video adapters.
- Check with your hardware vendor for any BIOS updates.
- Disable BIOS memory options such as caching or shadowing.

If you plan to debug this problem, you might find it difficult to obtain a stack trace. Parameter 2 (the exception address) should identify the driver or function that caused this problem.

If exception code 0x80000003 occurs, a hard-coded breakpoint or assertion was hit, but the computer was started with the **/NODEBUG** switch. This problem should rarely occur. If it occurs repeatedly, make sure that a kernel debugger is connected and that the computer is started with the **/DEBUG** switch.

If exception code 0x80000002 occurs, the trap frame supplies additional information.

If you do not know the specific cause of the exception, consider the following items:

- Hardware incompatibility. Make sure that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about compatibility with Windows 7 at the [Windows 7 Compatibility Center](#).
- Faulty device driver or system service. A faulty device driver or system service might be responsible for this error. Hardware issues, such as BIOS incompatibilities, memory conflicts, and IRQ conflicts can also generate this error.

If the bug check message lists a driver by name, disable or remove that driver. Also, disable or remove any drivers or services that were recently added. If the error occurs during the startup sequence and the system partition is formatted with NTFS file system, you might be able to use Safe Mode to rename or delete the faulty driver. If the driver is used as part of the system startup process in Safe Mode, you have to start the computer by using the Recovery Console to access the file.

If the problem is associated with Win32k.sys, the source of the error might be a third-party remote control program. If such software is installed, you can remove the service by starting the system by using the Recovery Console and then deleting the offending system service file.

Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing bug check 0x8E. You can disable memory caching of the BIOS to try to resolve the error. You should also run hardware diagnostics, especially the memory scanner, that the system manufacturer supplies. For more information about these procedures, see the owner's manual for your computer.

The error that generates this message can occur after the first restart during Windows Setup, or after Setup is finished. A possible cause of the error is lack of disk space for installation and system BIOS incompatibilities. For problems during Windows installation that are associated with lack of disk space, reduce the number of files on the target hard disk drive. Check for and delete any temporary files that you do not have to have, Internet cache files, application backup files, and .chk files that contain saved file fragments from disk scans. You can also use another hard disk drive with more free space for the installation.

You can resolve BIOS problems by upgrading the system BIOS version.

Bug Check 0x8F: PP0_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The PP0_INITIALIZATION_FAILED bug check has a value of 0x0000008F. This bug check indicates that the Plug and Play (PnP) manager could not be initialized.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PP0_INITIALIZATION_FAILED Parameters

None

Cause

An error occurred during Phase 0 initialization of the kernel-mode PnP manager.

Bug Check 0x90: PP1_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The PP1_INITIALIZATION_FAILED bug check has a value of 0x00000090. This bug check indicates that the Plug and Play (PnP) manager could not be initialized.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PP1_INITIALIZATION_FAILED Parameters

None

Cause

An error occurred during Phase 1 initialization of the kernel-mode PnP manager.

Phase 1 is where most of the initialization is done, including setting up the registry files and other environment settings for drivers to call during the subsequent I/O initialization.

Bug Check 0x92: UP_DRIVER_ON_MP_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The UP_DRIVER_ON_MP_SYSTEM bug check has a value of 0x00000092. This bug check indicates that a uniprocessor-only driver has been loaded on a multiprocessor system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UP_DRIVER_ON_MP_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	The base address of the driver
2	Reserved
3	Reserved
4	Reserved

Cause

A driver that is compiled to work only on uniprocessor machines has been loaded, but the Microsoft Windows operating system is running on a multiprocessor system with more than one active processor.

Bug Check 0x93: INVALID_KERNEL_HANDLE

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_KERNEL_HANDLE bug check has a value of 0x00000093. This bug check indicates that an invalid or protected handle was passed to **NtClose**.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_KERNEL_HANDLE Parameters

PARAMETER	DESCRIPTION
1	The handle that is passed to NtClose
2	0: The caller tried to close a protected handle 1: The caller tried to close an invalid handle
3	Reserved
4	Reserved

Cause

The INVALID_KERNEL_HANDLE bug check indicates that some kernel code (for example, a server, redirector, or another driver) tried to close an invalid handle or a protected handle.

Bug Check 0x94: KERNEL_STACK_LOCKED_AT_EXIT

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_STACK_LOCKED_AT_EXIT bug check has a value of 0x00000094. This bug check indicates that a thread exited while its kernel stack was marked as not swappable

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_STACK_LOCKED_AT_EXIT Parameters

None

Bug Check 0x96: INVALID_WORK_QUEUE_ITEM

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_WORK_QUEUE_ITEM bug check has a value of 0x00000096. This bug check indicates that a queue entry was removed that contained a **NULL** pointer.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_WORK_QUEUE_ITEM Parameters

PARAMETER	DESCRIPTION
1	The address of the queue entry whose flink or blink field is NULL .
2	The address of the queue that is being referenced. Typically, this queue is an ExWorkerQueue .
3	The base address of the ExWorkerQueue array. (This address helps you determine if the queue in question is indeed an ExWorkerQueue . If the queue is an ExWorkerQueue , the offset from this parameter will isolate the queue.)
4	Assuming the queue is an ExWorkerQueue , this value is the address of the worker routine that would have been called if the work item had been valid. (You can use this address to isolate the driver that is misusing the work queue.)

Cause

The INVALID_WORK_QUEUE_ITEM bug check occurs when **KeRemoveQueue** removes a queue entry whose **flink** or **blink** field is **NULL**.

Any queue misuse can cause this error. But typically this error occurs because worker thread work items are misused.

An entry on a queue can be inserted on the list only one time. When an item is removed from a queue, its **flink** field is set to **NULL**. Then, when this item is removed the second time, this bug check occurs.

In most situations, the queue that is being referenced is an **ExWorkerQueue** (executive worker queue). To help identify the driver that caused the error, Parameter 4 displays the address of the worker routine that would have been called if this work item had been valid. However, if the queue that is being referenced is not an **ExWorkerQueue**, this parameter is not useful.

Bug Check 0x97: BOUND_IMAGE_UNSUPPORTED

5/26/2017 • 1 min to read • [Edit Online](#)

The BOUND_IMAGE_UNSUPPORTED bug check has a value of 0x00000097.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x98: END_OF_NT_EVALUATION_PERIOD

5/26/2017 • 1 min to read • [Edit Online](#)

The END_OF_NT_EVALUATION_PERIOD bug check has a value of 0x00000098. This bug check indicates that the trial period for the Microsoft Windows operating system has ended.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

END_OF_NT_EVALUATION_PERIOD Parameters

PARAMETER	DESCRIPTION
1	The low-order 32 bits of the product expiration date
2	The high-order 32 bits of the product expiration date
3	Reserved
4	Reserved

Cause

Your installation of the Windows operating system is an evaluation unit with an expiration date. The trial period is over.

Bug Check 0x99: INVALID_REGION_OR_SEGMENT

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_REGION_OR_SEGMENT bug check has a value of 0x00000099. This bug check indicates that **ExInitializeRegion** or **ExInterlockedExtendRegion** was called with an invalid set of parameters.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_REGION_OR_SEGMENT Parameters

None

Bug Check 0x9A: SYSTEM_LICENSE_VIOLATION

5/26/2017 • 3 min to read • [Edit Online](#)

The SYSTEM_LICENSE_VIOLATION bug check has a value of 0x0000009A. This bug check indicates that the software license agreement has been violated.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SYSTEM_LICENSE_VIOLATION Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x00	0: The product should be WinNT 1: The product should be LanmanNT or ServerNT	A partial serial number	The first two characters of the product type from the product options	Offline product type changes have been attempted.
0x01	The registered evaluation time from source 1	A partial serial number	The registered evaluation time from an alternate source	Offline changes to the Microsoft Windows evaluation unit time period have been attempted.
0x02	The status code that is associated with the open failure	0	0	The setup key could not be opened.
0x03	The status code that is associated with the key lookup failure	0	0	The SetupType or SetupInProgress value from the setup key is missing, so setup mode could not be detected.
0x04	The status code that is associated with the key lookup failure	0	0	The SystemPrefix value from the setup key is missing.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x05	(See the setup code)	An invalid value was found in licensed processors	The officially licensed number of processors	Offline changes to the number of licensed processors have been attempted.
0x06	The status code that is associated with the open failure	0	0	The ProductOptions key could not be opened.
0x07	The status code that is associated with the read failure	0	0	The ProductType value could not be read.
0x08	The status code that is associated with the Change Notify failure	0	0	Change Notify on ProductOptions failed.
0x09	The status code that is associated with the Change Notify failure	0	0	Change Notify on SystemPrefix failed.
0x0A	0	0	0	An NTW system was converted to an NTS system.
0x0B	The status code that is associated with the change failure	0	0	The reference of the setup key failed.
0x0C	The status code that is associated with the change failure	0	0	The reference of the product options key failed.
0x0D	The status code that is associated with the failure	0	0	The attempt to open ProductOptions in the worker thread failed.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x0F	The status code that is associated with the failure	0	0	The attempt to open the setup key failed.
0x10	The status code that is associated with the failure	0: set value failed 1: Change Notify failed	0	A failure occurred in the setup key worker thread.
0x11	The status code that is associated with the failure	0: set value failed 1: Change Notify failed	0	A failure occurred in the product options key worker thread.
0x12	The status code that is associated with the failure	0	0	Unable to open the LicenseInfoSuite s key for the suite.
0x13	The status code that is associated with the failure	0	0	Unable to query the LicenseInfoSuite s key for the suite.
0x14	The size of the memory allocation	0	0	Unable to allocate memory.
0x15	The status code that is associated with the failure	Reserved	0	Unable to reset the ConcurrentLimit value for the suite key.
0x16	The status code that is associated with the failure	0	0	Unable to open the license key for a suite product.
0x17	The status code that is associated with the failure	0	0	Unable to reset the ConcurrentLimit value for a suite product.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x18	The status code that is associated with the open failure	Reserved	0	Unable to start the Change Notify for the LicenseInfoSuite s.
0x19	0	0	0	A suite is running on a system that must be PDC.
0x1A	The status code that is associated with the failure	0	0	A failure occurred when enumerating the suites.
0x1B	0	0	0	Changes to the policy cache were attempted.

Cause

The Microsoft Windows operating system detects a violation of the software license agreement.

A user might have tried to change the product type of an offline system or change the trial period of an evaluation unit of Windows. For more information about the specific violation, see the parameter list.

Bug Check 0x9B: UDFS_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The UDFS_FILE_SYSTEM bug check has a value of 0x0000009B. This bug check indicates that a problem occurred in the UDF file system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UDFS_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	The source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	If UdfExceptionFilter is on the stack, this parameter specifies the address of the exception record.
3	If UdfExceptionFilter is on the stack, this parameter specifies the address of the context record.
4	Reserved.

Cause

The UDFS_FILE_SYSTEM bug check might be caused disk corruption. Corruption in the file system or bad blocks (sectors) on the disk can induce this error. Corrupted SCSI and IDE drivers can also adversely affect the system's ability to read and write to the disk and cause the error.

This bug check might also occur if nonpaged pool memory is full. If the nonpaged pool memory is full, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver that requires nonpaged pool memory can also trigger this error.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command with Parameter 3, and then use [.kb \(Display Stack Backtrace\)](#).

To resolve a disk corruption problem: Check Event Viewer for error messages from SCSI and FASTFAT (System Log) or Autochk (Application Log) that might help identify the device or driver that is causing the error. Disable any virus scanners, backup application, or disk defragmenter tools that continually monitor the system. You should also run hardware diagnostics that the system manufacturer supplies. For more information about these procedures, see the owner's manual for your computer. Run **Chkdsk /f /r** to detect and resolve any file system structural corruption. You must restart the system before the disk scan begins on a system partition.

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This memory increases the quantity of nonpaged pool memory that is available to the kernel.

Bug Check 0x9C: MACHINE_CHECK_EXCEPTION

5/26/2017 • 2 min to read • [Edit Online](#)

The MACHINE_CHECK_EXCEPTION bug check has a value of 0x0000009C. This bug check indicates that a fatal machine check exception has occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MACHINE_CHECK_EXCEPTION Parameters

The four parameters that are listed in the message have different meanings, depending on the processor type.

If the processor is based on an older x86-based architecture and has the Machine Check Exception (MCE) feature but not the Machine Check Architecture (MCA) feature (for example, the Intel Pentium processor), the parameters have the following meaning.

PARAMETER	DESCRIPTION
1	The low 32 bits of P5_MC_TYPE Machine Service Report (MSR)
2	The address of the MCA_EXCEPTION structure
3	The high 32 bits of P5_MC_ADDR MSR
4	The low 32 bits of P5_MC_ADDR MSR

If the processor is based on a newer x86-based architecture and has the MCA feature and the MCE feature (for example, any Intel Processor of family 6 or higher, such as Pentium Pro, Pentium IV, or Xeon), or if the processor is an x64-based processor, the parameters have the following meaning.

PARAMETER	DESCRIPTION
1	The bank number
2	The address of the MCA_EXCEPTION structure
3	The high 32 bits of MCI_STATUS MSR for the MCA bank that had the error
4	The low 32 bits of MCI_STATUS MSR for the MCA bank that had the error

On an Itanium-based processor, the parameters have the following meaning.

Note Parameter 1 indicates the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x1	The address of the log	The size of the log	0	
0x2	The address of the log	The size of the log	The error code	The system abstraction layer (SAL) returned an error for SAL_GET_STATEIN FO while processing MCA.
0x3	The address of the log	The size of the log	The error code	SAL returned an error for SAL_CLEAR_STAT EINFO while it processed MCA.
0x4	The address of the log	The size of the log	0	Firmware (FW) reported a fatal MCA.
0x5	The address of the log	The size of the log	0	<p>There are two possible causes:</p> <ul style="list-style-type: none"> • SAL reported a recoverable MCA, but this recovery is not currently supported • SAL generated an MCA but could not produce an error record.
0xB	The address of the log	The size of the log	0	

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0xC	The address of the log	The size of the log	The error code	SAL returned an error for SAL_GET_STATEIN FO while processing an INIT event.
0xD	The address of the log	The size of the log	The error code	SAL returned an error for SAL_CLEAR_STAT EINFO while it processed an INIT event.
0xE	The address of the log	The size of the log	0	

Remarks

In Windows Vista and later operating systems, this bug check occurs only in the following circumstances.

- WHEA is not fully initialized.
- All processors that rendezvous have no errors in their registers.

For other circumstances, this bug check has been replaced with [bug Check 0x124](#):

[WHEA_UNCORRECTABLE_ERROR](#) in Windows Vista and later operating systems.

For more information about Machine Check Architecture (MCA), see the Intel or AMD Web sites.

Bug Check 0x9E: USER_MODE_HEALTH_MONITOR

5/26/2017 • 1 min to read • [Edit Online](#)

The USER_MODE_HEALTH_MONITOR bug check has a value of 0x0000009E. This bug check indicates that one or more critical user-mode components failed to satisfy a health check.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

USER_MODE_HEALTH_MONITOR Parameters

PARAMETER	DESCRIPTION
1	The process that failed to satisfy a health check in the configured time-out
2	The health monitoring time-out, in seconds
3	Reserved
4	Reserved

Cause

Hardware mechanisms, such as watchdog timers, can detect that basic kernel services are not executing. However, resource starvation issues (including memory leaks, lock contention, and scheduling priority misconfiguration) can block critical user-mode components without blocking deferred procedure calls (DPCs) or draining the non-paged pool.

Kernel components can extend watchdog timer functionality to user mode by periodically monitoring critical applications. This bug check indicates that a user-mode health check failed in a way that prevents graceful shutdown. This bug check restores critical services by restarting or enabling application failover to other servers.

On the Microsoft Windows Server 2003, Enterprise Edition, Windows Server 2003, Datacenter Edition, and Windows 2000 with Service Pack 4 (SP4) operating systems, a user-mode hang can also cause this bug check. The bug check occurs in this situation only if the user has set **HangRecoveryAction** to a value of 3.

(Developer Content) Bug Check 0x9F: DRIVER_POWER_STATE_FAILURE

5/26/2017 • 7 min to read • [Edit Online](#)

This bug check has a value of 0x0000009F. This bug check indicates that the driver is in an inconsistent or invalid power state.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_POWER_STATE_FAILURE Parameters

Parameter 1 indicates the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x1	The device object	Reserved	Reserved	The device object that is being freed still has an outstanding power request that it has not completed.
0x2	The target device's device object, if it is available	The device object	The driver object, if it is available	The device object completed the I/O request packet (IRP) for the system power state request, but it did not call PoStartNextPowerIrp .
0x3	The physical device object (PDO) of the stack	The functional device object (FDO) of the stack. In Windows 7 and later, nt!TRIAGE_9F_POWER.	The blocked IRP	A device object has been blocking an IRP for too long a time.
0x4	Time-out value, in seconds.	The thread currently holding onto the Plug-and-Play (PnP) lock.	In Windows 7 and later, nt!TRIAGE_9F_POWER.	The power state transition timed out waiting to synchronize with the PnP subsystem.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x500	Reserved	The target device's device object, if available	Device object	The device object completed the IRP for the system power state request, but it did not call PoStartNextPowerIrp .

Cause

For a description of the possible causes, see the description of each code in the Parameters section.

Debugging bug check 0x9F when Parameter 1 equals 0x3

- In a kernel debugger, use the **!analyze -v** command to perform the initial bug check analysis. The verbose analysis displays the address of the **nt!TRIAGE_9F_POWER** structure, which is in Arg3.

```
kd>!analyze -v
*****
*                               *
*             Bugcheck Analysis
*                               *
*****
*****

DRIVER_POWER_STATE_FAILURE (9f)
A driver has failed to complete a power IRP within a specific time.
Arguments:
Arg1: 0000000000000003, A device object has been blocking an Irp for too long a time
Arg2: fffffa8007b13440, Physical Device Object of the stack
Arg3: fffff8000386c3d8, nt!TRIAGE_9F_POWER on Win7 and higher, otherwise the Functional Device Object
of the stack
Arg4: fffffa800ab61bd0, The blocked IRP
```

The **nt!TRIAGE_9F_POWER** structure provides additional bug check information that might help you determine the cause of this bug check. The structure can provide a list of all outstanding power IRPs, a list of all power IRP worker threads, and a pointer to the delayed system worker queue.

- Use the **dt (Display Type)** command and specify the **nt!TRIAGE_9F_POWER** structure using the address from Arg3.

```
0: kd> dt nt!TRIAGE_9F_POWER fffff8000386c3d8
+0x000 Signature      : 0x8000
+0x002 Revision       : 1
+0x008 IrpList        : 0xfffff800`01c78bd0 _LIST_ENTRY [ 0xfffffa80`09f43620 -
0xfffffa80`0ad00170 ]
+0x010 ThreadList      : 0xfffff800`01c78520 _LIST_ENTRY [ 0xfffff880`009cdb98 -
0xfffff880`181f2b98 ]
+0x018 DelayedWorkQueue : 0xfffff800`01c6d2d8 _TRIAGE_EX_WORK_QUEUE
```

The **dt (Display Type)** command displays the structure. You can use various debugger commands to follow the **LIST_ENTRY** fields to examine the list of outstanding IRPs and the power IRP worker threads.

- Use the **!irp** command to examine the IRP that was blocked. The address of this IRP is in Arg4.

```

0: kd> !irp ffffffa800ab61bd0

```

- If you are working with a KMDF driver, use the [Windows Driver Framework Extensions](#) (!wdfkd) to gather additional information.

Use **!wdfkd.wdflogdump** <your driver name>, to see if KMDF is waiting for you to ACK any pending requests.

Use **!wdfkd.wdfdevicequeues** <your WDFDEVICE> to examine all outstanding requests and what state they are in.

- Use the **!stacks** extension to examine the state of every thread and look for a thread that might be holding up the power state transition.
- To help you determine the cause of the error, consider the following questions:
 - What are the characteristics of the physical device object (PDO) driver (Arg2)?
 - Can you find the blocked thread? When you examine the thread with the **!thread** debugger command, what does the thread consist of?
 - Is there IO associated with the thread that is blocking it? What symbols are on the stack?

- When you examine the blocked power IRP, what do you notice?
- What is the PnP minor function code of the power IRP?

Debugging bug check 0x9F when Parameter 1 equals 0x4

- In a kernel debugger, use the **!analyze -v** command to perform the initial bug check analysis. The verbose analysis displays the address of the **nt!TRIAGE_9F_PNP** structure, which is in Parameter 4 (arg4).

```
kd> !analyze -v
*****
*          Bugcheck Analysis
*
*****
DRIVER_POWER_STATE_FAILURE (9f)
A driver has failed to complete a power IRP within a specific time (usually 10 minutes).
Arguments:
Arg1: 00000004, The power transition timed out waiting to synchronize with the Pnp
      subsystem.
Arg2: 00000258, Timeout in seconds.
Arg3: 84e01a70, The thread currently holding on to the Pnp lock.
Arg4: 82931b24, nt!TRIAGE_9F_PNP on Win7
```

...

The **nt!TRIAGE\9F\PNP** structure provides additional bug check information that might help you determine the cause of the error. The **nt!TRIAGE\9F\PNP** structure provides a pointer to a structure that contains the list of dispatched (but not completed) PnP IRPs and provides a pointer to the delayed system worker queue.

- Use the **dt (Display Type)** command and specify the **nt!TRIAGE_9F_PNP** structure and the address that you found in Arg4.

```
kd> dt nt!TRIAGE_9F_PNP 82931b24
+0x000 Signature      : 0x8001
+0x002 Revision       : 1
+0x004 CompletionQueue : 0x82970e20 _TRIAGE_PNP_DEVICE_COMPLETION_QUEUE
+0x008 DelayedWorkQueue : 0x829455bc _TRIAGE_EX_WORK_QUEUE
```

The **dt (Display Type)** command displays the structure. You can use debugger commands to follow the **LIST_ENTRY** fields to examine the list of outstanding PnP IRPs.

To help you determine the cause of the error, consider the following questions:

- Is there an IRP associated with the thread?
- Is there any IO in the CompletionQueue?
- What symbols are on the stack?
- Refer to the additional techniques described above under parameter 0x3.

Resolution

If you are not equipped to debug this problem using the techniques described above, you can use some basic troubleshooting techniques.

- If you recently added hardware to the system, try removing or replacing it. Or check with the manufacturer

to see if any patches are available.

- If new device drivers or system services have been added recently, try removing or updating them. Try to determine what changed in the system that caused the new bug check code to appear.
- Look in **Device Manager** to see if any devices are marked with the exclamation point (!). Review the events log displayed in driver properties for any faulting driver. Try updating the related driver.
- Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.
- To try and isolate the cause, temporally disable power save using control panel, power options. Some driver issues are related to the various states of system hibernation and the suspending and resumption of power.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- Check with the manufacturer to see if an updated system BIOS or firmware is available.

Bug Check 0xA0: INTERNAL_POWER_ERROR

5/31/2017 • 9 min to read • [Edit Online](#)

The INTERNAL_POWER_ERROR bug check has a value of 0x000000A0. This bug check indicates that the power policy manager experienced a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INTERNAL_POWER_ERROR Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x1	1: A device has overrun its maximum number of reference counts. 2, 3, or 4: (Windows Server 2003, Windows XP, and Windows 2000 only) Too many inrush power IRPs have been queued. 5: (Windows Server 2003, Windows XP, and Windows 2000 only) The power IRP has been sent to a passive level device object. 6: The system has failed to allocate a necessary power IRP.	If Parameter 2 has a value of 1, the maximum number of references allowed. If Parameter 2 has a value of 2, 3, or 4, the maximum number of pending IRPs allowed. If Parameter 2 has a value of 6, the target device object.	If Parameter 2 has value of 6, indicates whether this is a system (0x0) or device (0x1) power IRP.	An error occurred during the handling of the power I/O request packet (IRP).
0x2	Reserved	Reserved	Reserved	An internal failure has occurred while attempting to process a power event. For more information, see Debugging bug check 0xA0 when parameter 1 equals 0x2 .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x3	The expected checksum	The actual checksum	The line number of the failure	The checksum for a hibernation context page does not match its expected checksum.
0x4	The expected checksum	The actual checksum	The line number of the failure	The checksum for a page about to be written to the hibernation file does not match its expected checksum.
0x5	Reserved	Reserved	Reserved	An unknown shutdown code has been sent to the system shutdown handler.
0x7	Reserved	Reserved	Reserved	An unhandled exception has occurred. For more information, see Debugging bug check 0xA0 when parameter 1 equals 0x7 .
0x8	This parameter is always set to 0x100.	The device object	POWER_CHANNEL_SUMMARY	A fatal error occurred while processing a system power event.
0x9	Status code	Mirroring phase	Reserved	A fatal error occurred while preparing the hibernate file.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0xA	<p>0: A bug check was requested immediately upon resuming.</p> <p>1: A bug check was requested during resume after all non-pageable devices had been powered on.</p> <p>2: A bug check was requested during resume after all devices had been powered on.</p>	Reserved	Reserved	A bug check was requested when waking for debugging purposes.
0xB	<p>Size of the hibernation file.</p> <p>0: HIBERFILE_PROG RESS_FREE_MAP</p> <p>1: HIBERFILE_PROG RESS_RESUME_CONTEXT</p> <p>2: HIBERFILE_PROG RESS_PROCESSOR_STATEEE</p> <p>3: HIBERFILE_PROG RESS_MEMORY_RANGES</p> <p>4: HIBERFILE_PROG RESS_TABLE_PAGES</p> <p>5: HIBERFILE_PROG RESS_MEMORY_IMAGE</p>	<p>Hibernation progress before running out of space</p> <p>0: HIBERFILE_PROG RESS_FREE_MAP</p> <p>1: HIBERFILE_PROG RESS_RESUME_CONTEXT</p> <p>2: HIBERFILE_PROG RESS_PROCESSOR_STATEEE</p> <p>3: HIBERFILE_PROG RESS_MEMORY_RANGES</p> <p>4: HIBERFILE_PROG RESS_TABLE_PAGES</p> <p>5: HIBERFILE_PROG RESS_MEMORY_IMAGE</p>	<p>Size of the remaining memory ranges.</p>	The hibernation file is too small.
0xC	Status code	Dump stack context	Reserved	The dump stack failed to initialize.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x101	Reserved	Exception pointer.	Reserved	An unhandled exception occurred while processing a system power event. For more information, see Debugging bug check 0xA0 when parameter 1 equals 0x101 .
0x102	Reserved	DUMP_INITIALIZATION_CONTEXT	POP_HIBER_CONTEXT	The hibernation working buffer size is not page aligned.
0x103	Reserved	POP_HIBER_CONTEXT	Reserved	All working pages have failed to be accounted for during the hibernation process.
0x104	Reserved	POP_HIBER_CONTEXT	Reserved	An attempt was made to map internal hibernation memory while the internal memory structures were locked.
0x105	Reserved	POP_HIBER_CONTEXT	Reserved	An attempt was made to map internal hibernation memory with an unsupported memory type flag.
0x106	Reserved	The memory descriptor list (MDL)	Reserved	A memory descriptor list was created during the hibernation process which describes memory that is not paged-aligned.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x107	Reserved	POP_HIBER_CONTEXT	PO_MEMORY_RANGE_ARRAY	A data mismatch has occurred in the internal hibernation data structures.
0x108	Reserved	POP_HIBER_CONTEXT	Reserved	The disk subsystem failed to properly write part of the hibernation file.
0x109	Reserved	Expected checksum	Actual checksum	The checksum for the processor state data does not match its expected checksum.
0x10A	Reserved	POP_HIBER_CONTEXT	NTSTATUS	The disk subsystem failed to properly read or write part of the hibernation file.
0x10B	Reserved	Current hibernation progress	Reserved	An attempt was made to mark pages for the boot phase of hibernation at the wrong time using the PoSetHiberRange API.
0x10C	Reserved	Flags provided to the API	Length to mark	The PoSetHiberRange API was called with invalid parameters.
0x200	Reserved	DEVICE_OBJECT	DEVICE_OBJECT_POWER_EXTENSION	An unknown device type is being checked for an idle state.
0x300	Reserved	DEVICE_OBJECT	IRP	An unknown status was returned from a battery power IRP.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x301	Reserved	DEVICE_OBJECT	IRP	The battery has entered an unknown state.
0x400	Reserved	IO_STACK_LOCATION	DEVICE_OBJECT	A device has overrun its maximum number of reference counts.
0x401	Reserved	Pending IRP list	DEVICE_OBJECT	Too many inrush power IRPs have been queued.
0x402	Reserved	Pending IRP list	DEVICE_OBJECT	Too many inrush power IRPs have been queued.
0x403	Reserved	Pending IRP list	DEVICE_OBJECT	Too many inrush power IRPs have been queued.
0x404	Reserved	IO_STACK_LOCATION	DEVICE_OBJECT	A power IRP has been sent to a passive-level device object.
0x500	Reserved	IRP	DEVICE_OBJECT	An unknown status was returned from a thermal power IRP.
0x600	DEVICE_OBJECT PDO	Reserved	Reserved	A driver has attempted a duplicate registration with the Power Runtime Framework.
0x601	POP_FX_DEVICE device	PEP_DEVICE_REGISTERED PEP	Reserved	No Power Engine Plugins accepted device registration.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x602	DEVICE_NODE device node	Sleep count	Reserved	Device node sleep count does not match its activation count.
0x603	POP_FX_PLUGIN	Work request type	Reserved	A Power Engine Plugin made an invalid work request.
0x605	Notification ID	POP_FX_PLUGIN	Reserved	A Power Engine Plugin failed to accept mandatory device power management notification.
0x606	POP_FX_COMPONENT	POP_FX_COMPONENT_FLAGS	New condition for the component	A Power Engine Plugin attempted to transition a critical system resource component to an Active (or Idle) condition when the resource was already Active (or Idle).
0x607	POP_FX_DEVICE	NTSTATUS	Reserved	The acquisition of a runtime power management framework device-removal lock failed when it was required to succeed.
0x608	POP_FX_COMPONENT	POP_FX_COMPONENT_FLAGS	Reserved	A driver has attempted to transition a component to idle without a preceding active request.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x609	POP_FX_PLUGIN	POP_FX_DEVICE	Duplicate Request Type 0: DevicePowerRequired 1: DevicePowerNotRequired	A Power Engine Plugin has requested either device power required or device power not required without an intervening request of the opposite type.
0x610	POP_FX_PLUGIN	POP_FX_DEVICE	Reserved	A Power Engine Plugin has requested device power not required while a previous device power required request is outstanding.
0x611	POP_FX_PLUGIN	POP_FX_DEVICE	Invalid component index	A Power Engine Plugin has requested an operation on an invalid component.
0x612	POP_FX_PLUGIN PowerEnginePlugin	Reserved	Reserved	A Power Engine Plugin has requested additional work to be done in the context of a device notification where no buffer was supplied by PO for the request.
0x613	POP_FX_DEVICE	Component index	Operation 0: Complete device power not required 1: Report device powered on 2: Complete idle condition	A driver has attempted to complete a request when no such outstanding request is pending.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x614	POP_FX_DEVICE	Component index	<p>Illegal parameter</p> <p>0: PO_FX_FLAG_BLOCKING used at IRQL >= DISPATCH_LEVEL</p> <p>1: PO_FX_FLAG_BLOCKING and PO_FX_FLAG_ASYNC_ONLY both specified</p> <p>2: Invalid component index</p>	A driver has requested an active/idle transition on a component with an illegal parameter.
0x615	POP_FX_PLUGIN	POP_FX_COMPONENT	<p>Illegal Action</p> <p>0: Component not in idle state 0</p> <p>1: Component is already active</p> <p>2: No outstanding activation request</p> <p>3: Outstanding idle state transition</p>	A Power Engine Plugin has illegally indicated the completion of a component activation.
0x616	POP_FX_PLUGIN	POP_FX_COMPONENT	<p>Illegal Action</p> <p>0: Invalid idle state</p> <p>1: Component is already in the requested state</p> <p>2: Requested a non-zero idle state without passing through idle state 0</p>	A Power Engine Plugin has illegally requested a component idle state transition.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x666	PPOP_PEP_ACTIVITY	New activity type 0: DevicePowerOn 1: ComponentIdleStateChange 2: ComponentActivating 3: ComponentActive 4: DevicePowerOff 5: DeviceSuspend	Conflicting activity type 0: DevicePowerOn 1: ComponentIdleStateChange 2: ComponentActivating 3: ComponentActive 4: DevicePowerOff 5: DeviceSuspend	The default Power Engine Plugin has attempted to trigger a new activity that conflicts with another activity.
0x667	POP_PEP_ACTIVITY	Activity type 0: DevicePowerOn 1: ComponentIdleStateChange 2: ComponentActivating 3: ComponentActive 4: DevicePowerOff 5: DeviceSuspend	POP_PEP_ACTIVITY_STATUS	Default Power Engine Plugin has attempted to complete an activity that is not running.
0x700	PEPHANDLE	PEP_PPM_IDLE_SELECT	Reserved	A Power Engine Plugin has specified invalid processor idle dependencies.
0x701	The index of the selected idle state of the hung processor	The PRCB address of the hung processor	The index of the hung processor	A processor was not able to complete an idle transition within the allocated interval. This indicates the specified processor is hung.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x702	The index of the selected idle state of the processor	The idle synchronization state of the processor	The PRCB address of the hung processor	A processor woke up from a non-interruptible state without the the OS initiating an explicit wake through the PEP (using the necessary PPM idle synchronization).

Resolution

General Notes

In the preceding table, several of the parameters are pointers to structures. For example, if Parameter 2 is listed as DEVICE_OBJECT, then Parameter 2 is a pointer to a DEVICE_OBJECT structure. Some of the structures are defined in wdm.h, which is included in the Windows Driver Kit. For example, the following structures are defined in wdm.h.

- EXCEPTION_POINTERS
- DEVICE_OBJECT
- IO_STACK_LOCATION
- PEP_DEVICE_REGISTER

Some of the structures that appear in the preceding table are not defined in any public header file. You can see the definitions of those structures by using the **dt** debugger command. The following example shows how to use the **dt** command to see the **DEVICE_OBJECT_POWER_EXTENSION** structure.

```
3: kd> dt nt!DEVICE_OBJECT_POWER_EXTENSION
+0x000 IdleCount      : Uint4B
+0x004 BusyCount      : Uint4B
+0x008 BusyReference  : Uint4B
+0x00c TotalBusyCount : Uint4B
+0x010 ConservationIdleTime : Uint4B
+0x014 PerformanceIdleTime : Uint4B
+0x018 DeviceObject    : Ptr64 _DEVICE_OBJECT
+0x020 IdleList        : _LIST_ENTRY
+0x030 IdleType        : _POP_DEVICE_IDLE_TYPE
+0x034 IdleState       : _DEVICE_POWER_STATE
+0x038 CurrentState    : _DEVICE_POWER_STATE
+0x040 Volume          : _LIST_ENTRY
+0x050 Specific         : <unnamed-tag>
```

The following procedures will help you debug certain instances of this bug check.

Debugging bug check 0xA0 when Parameter 1 equals 0x2

1. Examine the stack. Look for the **ntoskrnl!PopExceptionFilter** function. This function contains the following code as its first argument.

```
(error_code << 16) | _LINE_
```

If the caller is **PopExceptionFilter**, the first argument to this function is of type PEXCEPTION_POINTERS. Note the value of this argument.

2. Use the **dt (Display Type)** command and specify the value that you found in the previous step as *argument*.

```
dt nt!_EXCEPTION_POINTERS argument
```

This command displays the structure. Note the address of the context record.

3. Use the **.cxr (Display Context Record)** command and specify the context record that you found in the previous step as *record*.

```
.cxr record
```

This command sets the register context to the proper value.

4. Use a variety of commands to analyze the source of the error. Start with **kb (Display Stack Backtrace)**.

Debugging bug check 0xA0 when Parameter 1 equals 0x7

1. Examine the stack. Look for the **ntoskrnl!PopExceptionFilter** function. The first argument to this function is of type PEXCEPTION_POINTERS. Note the value of this argument.
2. Use the **dt (Display Type)** command and specify the value that you found in the previous step as *argument*.

```
dt nt!_EXCEPTION_POINTERS argument
```

This command displays the structure. Note the address of the context record.

3. Use the **.cxr (Display Context Record)** command and specify the context record that you found in the previous step as *record*.

```
.cxr record
```

This command sets the register context to the proper value.

4. Use a variety of commands to analyze the source of the error. Start with **kb (Display Stack Backtrace)**.

Debugging bug check 0xA0 when Parameter 1 equals 0x101

1. Use the **dt (Display Type)** command and specify the value of Parameter 3 as *argument*.

```
dt nt!_EXCEPTION_POINTERS argument
```

This command displays the structure. Note the address of the context record.

2. Use the **.cxr (Display Context Record)** command and specify the context record that you found in the previous step as *record*.

```
.cxr record
```

This command sets the register context to the proper value.

3. Use a variety of commands to analyze the source of the error. Start with **kb (Display Stack Backtrace)**.

Bug Check 0xA1: PCI_BUS_DRIVER_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The PCI_BUS_DRIVER_INTERNAL bug check has a value of 0x000000A1. This bug check indicates that the PCI Bus driver detected inconsistency problems in its internal structures and could not continue.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PCI_BUS_DRIVER_INTERNAL Parameters

None

Bug Check 0xA2: MEMORY_IMAGE_CORRUPT

5/26/2017 • 1 min to read • [Edit Online](#)

The MEMORY_IMAGE_CORRUPT bug check has a value of 0x000000A2. This bug check indicates that corruption has been detected in the image of an executable file in memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MEMORY_IMAGE_CORRUPT Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x02	If Parameter 3 is zero: The page number in the table page that failed If Parameter 3 is nonzero: The page number with the failing page run index	Zero, or the index that failed to match the run	0	A table page check failure occurred.
0x03	The starting physical page number of the range	The length (in pages) of the range	The page number of the table page that contains this run	The checksum for the range of memory listed is incorrect.

Cause

A cyclic redundancy check (CRC) check on the memory range has failed.

On a system wake operation, various regions of memory might be checked to guard against memory failures.

Bug Check 0xA3: ACPI_DRIVER_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The ACPI_DRIVER_INTERNAL bug check has a value of 0x000000A3. This bug check indicates that the ACPI driver detected an internal inconsistency.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ACPI_DRIVER_INTERNAL Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	Reserved

Cause

An inconsistency in the ACPI driver is so severe that continuing to run would cause serious problems.

One possible source of this problem is a BIOS error.

Bug Check 0xA4: CNSS_FILE_SYSTEM_FILTER

5/26/2017 • 1 min to read • [Edit Online](#)

The CNSS_FILE_SYSTEM_FILTER bug check has a value of 0x000000A4. This bug check indicates that a problem occurred in the CNSS file system filter.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CNSS_FILE_SYSTEM_FILTER Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") identify the source file by its identifier number. The low 16 bits identify the source line in the file where the bug check occurred.
2	Reserved
3	Reserved
4	Reserved

Cause

The CNSS_FILE_SYSTEM_FILTER bug check might occur because nonpaged pool memory is full. If the nonpaged pool memory is completely full, this error can stop the system. However, during the indexing process, if the amount of available nonpaged pool memory is very low, another kernel-mode driver that requires nonpaged pool memory can also trigger this error.

Resolution

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This memory increases the quantity of nonpaged pool memory available to the kernel.

Bug Check 0xA5: ACPI_BIOS_ERROR

5/26/2017 • 10 min to read • [Edit Online](#)

The ACPI_BIOS_ERROR bug check has a value of 0x000000A5. This bug check indicates that the Advanced Configuration and Power Interface (ACPI) BIOS of the computer is not fully compliant with the ACPI specification.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ACPI_BIOS_ERROR Parameters

Parameter 1 indicates the kind of the incompatibility. The meaning of the other parameters depends on the value of Parameter 1.

If the BIOS incompatibility is related to Plug and Play (PnP) or power management, the following parameters are used.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x01	ACPI's deviceExtension	ACPI's ResourceList	0: No resource list is found 1: No IRQ resource is found in list	ACPI cannot find the System Control Interrupt (SCI) vector in the resources that are handed to it when ACPI is started.
0x02				(See the table later on this page)
0x03	The ACPI object that was being run	The return value from the interpreter	The name of the control method (in ULONG format)	ACPI tried to run a control method while creating device extensions to represent the ACPI namespace, but this control method failed.
0x04	The ACPI extension that _PRW belongs to	A pointer to the method	The DataType returned (see Amli.h)	ACPI evaluated a _PRW and expected to find an integer as a package element.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x05	The ACPI extension that _PRW belongs to	A pointer to the _PRW	The number of elements in the _PRW	ACPI evaluated a _PRW, and the package that came back failed to contain at least two elements. The ACPI specification requires that two elements always be present in a _PRW.
0x06	The ACPI extension that _PRx belongs to	A pointer to the _PRx	A pointer to the name of the object to look for	ACPI tried to find a named object, but it could not find the object.
0x07	The ACPI extension that the method belongs to	A pointer to the method	The DataType returned (see Amli.h)	ACPI evaluated a method and expected to receive a buffer in return. However, the method returned some other data type.
0x08	The ACPI extension that the method belongs to	A pointer to the method	The DataType returned (see Amli.h)	ACPI evaluated a method and expected to receive an integer in return. However, the method returned some other data type.
0x09	The ACPI extension that the method belongs to	A pointer to the method	The DataType returned (see Amli.h)	ACPI evaluated a method and expected to receive a package in return. However, the method returned some other data type.
0x0A	The ACPI extension that the method belongs to	A pointer to the method	The DataType returned (see Amli.h)	ACPI evaluated a method and expected to receive a string in return. However, the method returned some other data type.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x0B	The ACPI extension that _EJD belongs to	The status that the interpreter returns	The name of the object that ACPI is trying to find	ACPI cannot find the object that an _EJD string references.
0x0C	The ACPI extension that ACPI found a dock device for	A pointer to the _EJD method	0: BIOS does not claim system is dockage 1: Duplicate device extensions for dock device	ACPI provides faulty or insufficient information for dock support.
0x0D	The ACPI extension that ACPI needs the object for	The (ULONG) name of the method that ACPI looked for	0: Base case 1: Conflict	ACPI could not find a required method or object in the namespace. This bug check code is used if there is no _HID or _ADR present.
0x0E	The NS PowerResource that ACPI needs the object for	The (ULONG) name of the method that ACPI looked for	0: Base case	ACPI could not find a required method or object in the namespace for a power resource (or entity other than a "device"). This bug check code is used if there is no _ON, _OFF, or _STA present for a power resource.
0x0F	The current buffer that ACPI was parsing	The buffer's tag	The specified length of the buffer	ACPI could not parse the resource descriptor.
0x10				(See the table later on this page)
0x11				(See the table later on this page)

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x14	The current buffer that ACPI was parsing	The buffer's tag	A pointer to a variable that contains the ULONGLONG length of the buffer	ACPI could not parse the resource descriptor. The length exceeds MAXULONG.
0x15	The ACPI Machine Language (AML) context	1: Failed to load table 2: The Parameter Path String Object was not found 3: Failed to insert Parameter Data into the ParameterPath String Object 4: Out of system memory	The NT status code	ACPI had a fatal error when attempting to load a table.
0x16	A pointer to the parent NSOBJ	A pointer to the illegal child ACPI namespace object	Reserved	ACPI had a fatal error when processing an xSDT. An object was declared as a child of a parent that cannot have children.

If an interrupt routing failure or incompatibility has occurred, the following parameters are used.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x2001	InterruptModel (integer)	The return value from the interpreter	A pointer to the PIC control method	ACPI tried to evaluate the PIC control method but failed.
0x10001	A pointer to the device object	A pointer to the parent of the device object	A pointer to the _PRT object (See the following Comments section)	ACPI tried to do interrupt routing, but failed.
0x10002	A pointer to the device object	A pointer to the string name that ACPI was looking for but could not find	A pointer to the _PRT object (See the following Comments section)	ACPI could not find the link node referenced in a _PRT.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x10003	A pointer to the device object	<p>The device ID or function number.</p> <p>This DWORD is encoded as follows: bits 5:0 are the PCI device number, and bits 8:6 are the PCI function number</p>	<p>A pointer to the _PRT object</p> <p>(See the following Comments section)</p>	ACPI could not find a mapping in the _PRT package for a device.
0x10005	<p>A pointer to the _PRT object</p> <p>(See the following Comments section)</p>	<p>A pointer to the current _PRT element.</p> <p>(This pointer is an index into the _PRT.)</p>	<p>The device ID or function number.</p> <p>This DWORD is encoded as follows: bits 15:0 are the PCI function number, and bits 31:16 are the PCI device number</p>	<p>ACPI found an entry in the _PRT that the function ID is not all F's for.</p> <p>(The generic format for a _PRT entry is that the device number is specified, but the function number is not.)</p>
0x10006	<p>A pointer to the link node.</p> <p>(This device is missing the _DIS method.)</p>	0	0	<p>ACPI found a link node, but it cannot disable the node.</p> <p>(Link nodes must be disabled to allow for reprogramming.)</p>
0x10007	The vector that could not be found	0	0	The _PRT contained a reference to a vector that is not described in the I/O APIC entry's MAPIC table.
0x10008	The invalid interrupt level.	0	0	The ACPI SCI interrupt level is invalid.
0x10009	0	0	0	The Fixed ACPI Description Table (FADT) could not be located.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x1000A	0	0	0	The Root System Description Pointer (RSDP) or Extended System Description Table (XSDT) could not be located
0x1000B	The ACPI table signature	A pointer to the ACPI table	0	The length of the ACPI table is not consistent with the table revision.
0x20000	The I/O port in the Fixed Table	0	0	The PM_TMR_BLK entry in the Fixed ACPI Description Table doesn't point to a working ACPI timer block.

If a miscellaneous failure or incompatibility has occurred, the following parameters are used.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x20000	The I/O port in the Fixed Table	0	0	The PM_TMR_BLK entry in the Fixed ACPI Description Table does not point to a working ACPI timer block.

If Parameter 1 equals **0x02**, the ACPI BIOS could not process the resource list for the PCI root buses. In this case, Parameter 3 specifies the exact problem, and the remaining parameters have the following definitions.

PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
The ACPI extension for the PCI bus	0x0	A pointer to the QUERY_RESOURCES IRP	ACPI cannot convert the BIOS' resource list into the proper format. This probably represents an error in the BIOS' list encoding procedure.
The ACPI extension for the PCI bus	0x1	A pointer to the QUERY_RESOURCE_REQUIREMENTS IRP	ACPI cannot convert the BIOS' resource list into the proper format. This probably represents an error in the BIOS' list encoding procedure.

PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
The ACPI extension for the PCI bus	0x2	0	ACPI found an empty resource list.
The ACPI extension for the PCI bus	0x3	A pointer to the PNP CRS descriptor	ACPI could not find the current bus number in the CRS.
The ACPI extension for the PCI bus	A pointer to the resource list for PCI	A pointer to the E820 memory table	The list of resources that PCI claims to decode overlaps with the list of memory regions that the E820 BIOS interface reports. (This kind of conflict is never permitted.)

If Parameter 1 equals **0x10**, the ACPI BIOS could not determine the system-to-device-state mapping correctly. In this situation, Parameter 3 specifies the exact problem, and the remaining parameters have the following definitions.

PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
The ACPI extension whose mapping is needed	0x0	The DEVICE_POWER_STATE (this is "x+1")	_PRx was mapped back to a non-supported S-state.
The ACPI extension whose mapping is needed	0x1	The SYSTEM_POWER_STATE that cannot be mapped	ACPI cannot find a D-state to associate with the S-state.
The ACPI extension whose mapping is needed	0x2	The SYSTEM_POWER_STATE that cannot be mapped	The device claims to be able to wake the system when the system is in this S-state, but the system does not actually support this S-state.

If Parameter 1 equals **0x11**, the system could not enter ACPI mode. In this situation, Parameter 2 specifies the exact problem, and the remaining parameters have the following definitions.

PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x0	0	0	The system could not initialize the AML interpreter.
0x1	0	0	The system could not find RSDT.

PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE
0x2	0	0	The system could not allocate critical driver structures.
0x3	0	0	The system could not load RSDT.
0x4	0	0	The system could not load DDBs.
0x5	0	0	The system cannot connect the Interrupt vector.
0x6	0	0	SCI_EN never becomes set in PM1 Control Register.
0x7	A pointer to the table that had a bad checksum	Creator revision	The table checksum is incorrect.
0x8	A pointer to the table that ACPI failed to load	Creator revision	ACPI failed to load DDB.
0x9	FADT version	0	Unsupported firmware version.
0xA	0	0	The system could not find MADT.
0xB	0	0	The system could not find any valid Local SAPIC structures in the MADT.

Cause

The value of Parameter 1 indicates the error.

Resolution

If you are debugging this error, use the [!analyze -v](#) extension. This extension displays all the relevant data (device extensions, nsobjects, or whatever is appropriate to the specific error).

If you are not performing debugging, this error indicates that you have to obtain a new BIOS. Contact your vendor or visit the internet to get a new BIOS.

If you cannot obtain an updated BIOS, or the latest BIOS is still not ACPI compliant, you can turn off ACPI mode during text-mode setup. To turn off ACPI mode, press the F7 key when you are prompted to install storage drivers. The system does not notify you that the F7 key was pressed, but it silently disables ACPI and enables you to continue your installation.

Remarks

A PCI routing table (_PRT) is the ACPI BIOS object that specifies how all the PCI devices are connected to the interrupt controllers. A computer with multiple PCI buses might have multiple _PRTs.

You can display a _PRT in the debugger by using the **!acpikd.nsobj** extension together with the address of the _PRT object as its argument.

Bug Check 0xA7: BAD_EXHANDLE

5/26/2017 • 1 min to read • [Edit Online](#)

The BAD_EXHANDLE bug check has a value of 0x000000A7. This bug check indicates that the kernel-mode handle table detected an inconsistent handle table entry state.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BAD_EXHANDLE Parameters

None

Bug Check 0xAB: SESSION_HAS_VALID_POOL_ON_EXIT

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION_HAS_VALID_POOL_ON_EXIT bug check has a value of 0x000000AB. This bug check indicates that a session unload occurred while a session driver still held memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION_HAS_VALID_POOL_ON_EXIT Parameters

PARAMETER	DESCRIPTION
1	The session ID.
2	The number of paged pool bytes that are leaking.
3	The number of nonpaged pool bytes that are leaking.
4	The total number of paged and nonpaged allocations that are leaking. (The number of nonpaged allocations are in the upper half of this word, and paged allocations are in the lower half of this word.)

Cause

The SESSION_HAS_VALID_POOL_ON_EXIT bug check occurs because a session driver does not free its pool allocations before a session unload. This bug check can indicate a bug in Win32k.sys, Atmfd.dll, Rdpdd.dll, or a video or other driver.

Bug Check 0xAC: HAL_MEMORY_ALLOCATION

5/26/2017 • 1 min to read • [Edit Online](#)

The HAL_MEMORY_ALLOCATION bug check has a value of 0x000000AC. This bug check indicates that the hardware abstraction layer (HAL) could not obtain sufficient memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

HAL_MEMORY_ALLOCATION Parameters

PARAMETER	DESCRIPTION
1	The allocation size
2	0
3	A pointer to a string that contains the file name
4	Reserved

Cause

The HAL could not obtain non-paged memory pool for a system critical requirement.

These critical memory allocations are made early in system initialization, and the HAL_MEMORY_ALLOCATION bug check is not expected. This bug check probably indicates some other critical error such as pool corruption or massive consumption.

Bug Check 0xAD: VIDEO_DRIVER_DEBUG_REPORT_REQUEST

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_DRIVER_DEBUG_REPORT_REQUEST bug check has a value of 0x000000AD. This bug check indicates that the video port created a non-fatal minidump on behalf of the video driver during run time.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_DRIVER_DEBUG_REPORT_REQUEST Parameters

PARAMETER	DESCRIPTION
1	Driver-specific
2	Driver-specific
3	Driver-specific
4	The number of all reports that have been requested since boot time

Remarks

The video port created a non-fatal minidump on behalf of the video driver during run time because the video driver requested a debug report.

The VIDEO_DRIVER_DEBUG_REPORT_REQUEST bug check can be caused only by minidump creation, not by the creation of a full dump or kernel dump.

Bug Check 0xB1: BGI_DETECTED_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The BGI_DETECTED_VIOLATION bug check has a value of 0x000000B1.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BGI_DETECTED_VIOLATION Parameters

None

Bug Check 0xB4: VIDEO_DRIVER_INIT_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_DRIVER_INIT_FAILURE bug check has a value of 0x000000B4. This indicates that Windows was unable to enter graphics mode.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_DRIVER_INIT_FAILURE Parameters

None

Cause

The system was not able to go into graphics mode because no display drivers were able to start.

This usually occurs when no video miniport drivers are able to load successfully.

Bug Check 0xB8: ATTEMPTED_SWITCH_FROM_DPC

5/26/2017 • 1 min to read • [Edit Online](#)

The ATTEMPTED_SWITCH_FROM_DPC bug check has a value of 0x000000B8. This indicates that an illegal operation was attempted by a delayed procedure call (DPC) routine.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ATTEMPTED_SWITCH_FROM_DPC Parameters

PARAMETER	DESCRIPTION
1	The original thread causing the failure
2	The new thread
3	The stack address of the original thread
4	Reserved

Cause

A wait operation, attach process, or yield was attempted from a DPC routine. This is an illegal operation.

Resolution

The stack trace will lead to the code in the original DPC routine that caused the error.

Bug Check 0xB9: CHIPSET_DETECTED_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The CHIPSET_DETECTED_ERROR bug check has a value of 0x000000B9.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0xBA: SESSION_HAS_VALID_VIEWS_ON_EXIT

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION_HAS_VALID_VIEWS_ON_EXIT bug check has a value of 0x000000BA. This indicates that a session driver still had mapped views when the session unloaded.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION_HAS_VALID_VIEWS_ON_EXIT Parameters

PARAMETER	DESCRIPTION
1	The session ID
2	The number of mapped views that are leaking
3	The address of this session's mapped views table
4	The size of this session's mapped views table

Cause

This error is caused by a session driver not unmapping its mapped views prior to a session unload. This indicates a bug in win32k.sys, atmfd.dll, rdpdd.dll, or a video driver.

Bug Check 0xBB: NETWORK_BOOT_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The NETWORK_BOOT_INITIALIZATION_FAILED bug check has a value of 0x000000BB. This indicates that Windows failed to successfully boot off a network.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NETWORK_BOOT_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	The part of network initialization that failed. Possible values are: 1: Failure while updating the registry. 2: Failure while starting the network stack. Windows sends IOCTLs to the redirector and datagram receiver, then waits for the redirector to be ready. If it is not ready within a certain period of time, this error is issued. 3: Failure while sending the DHCP IOCTL to TCP. This is how Windows informs the transport of its IP address.
2	The failure status
3	Reserved
4	Reserved

Cause

This error is caused when Windows is booting off a network, and a critical function fails during I/O initialization.

Bug Check 0xBC: NETWORK_BOOT_DUPLICATE_ADDRESS

5/26/2017 • 1 min to read • [Edit Online](#)

The NETWORK_BOOT_DUPLICATE_ADDRESS bug check has a value of 0x000000BC. This indicates that a duplicate IP address was assigned to this machine while booting off a network.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NETWORK_BOOT_DUPLICATE_ADDRESS Parameters

PARAMETER	DESCRIPTION
1	The IP address, shown as a DWORD. An address of the form <i>aa.bb.cc.dd</i> will appear as 0xDDCCBAA.
2	The hardware address of the other machine. (For an Ethernet connection, see the following note.)
3	The hardware address of the other machine. (For an Ethernet connection, see the following note.)
4	The hardware address of the other machine. (For an Ethernet connection, this will be zero.)

Note When Parameter 4 equals zero, this indicates an Ethernet connection. In that case, the MAC address will be stored in Parameter 2 and Parameter 3. An Ethernet MAC address of the form *aa-bb-cc-dd-ee-ff* will cause Parameter 2 to equal 0xAABBCCDD, and Parameter 3 to equal 0xEEFF0000.

Cause

This error indicates that when TCP/IP sent out an ARP for its IP address, it got a response from another machine indicating a duplicate IP address.

When Windows is booting off a network, this is a fatal error.

Bug Check 0xBD: INVALID_HIBERNATED_STATE

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_HIBERNATED_STATE bug check has a value of 0x000000BD. This indicates that the hibernated memory image does not match the current hardware configuration. This bugcheck occurs when a system resumes from hibernate and discovers that the hardware has been changed while the system was hibernated.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_HIBERNATED_STATE Parameters

PARAMETER	DESCRIPTION
1	Hardware that was invalid. 1 : Number of installed processors is less than before the hibernation Value in Param 2: Number of processors before hibernation Value in Param 3: Number of processors after hibernation
2	Per Parameter 1
3	Per Parameter 1
4	Reserved

Bug Check 0xBE: ATTEMPTED_WRITE_TO_READONLY_MEMORY

5/26/2017 • 1 min to read • [Edit Online](#)

The ATTEMPTED_WRITE_TO_READONLY_MEMORY bug check has a value of 0x000000BE. This is issued if a driver attempts to write to a read-only memory segment.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ATTEMPTED_WRITE_TO_READONLY_MEMORY Parameters

PARAMETER	DESCRIPTION
1	Virtual address of attempted write
2	PTE contents
3	Reserved
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Bug Check 0xBF: MUTEX_ALREADY_OWNED

5/26/2017 • 1 min to read • [Edit Online](#)

The MUTEX_ALREADY_OWNED bug check has a value of 0x000000BF. This indicates that a thread attempted to acquire ownership of a mutex it already owned.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MUTEX_ALREADY_OWNED Parameters

PARAMETER	DESCRIPTION
1	The address of the mutex
2	The thread that caused the error
3	0
4	Reserved

Bug Check 0xC1: SPECIAL_POOL_DETECTED_MEMORY_CORRUPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The SPECIAL_POOL_DETECTED_MEMORY_CORRUPTION bug check has a value of 0x000000C1. This indicates that the driver wrote to an invalid section of the special pool.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SPECIAL_POOL_DETECTED_MEMORY_CORRUPTION Parameters

Parameter 4 indicates the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
Address that the driver tried to free	Reserved	0	0x20	A driver attempted to free pool which was not allocated.
Address that the driver tried to free	Bytes requested	Bytes calculated (actually given to the caller)	0x21, 0x22	A driver attempted to free a bad address.
Address that the driver tried to free	Address where bits are corrupted	Reserved	0x23	A driver freed an address, but nearby bytes within the same page have been corrupted.
Address that the driver tried to free	Address where bits are corrupted	Reserved	0x24	A driver freed an address, but bytes occurring after the end of the allocation have been overwritten.
Current IRQL	Pool type	Number of bytes	0x30	A driver attempted to allocate pool at an incorrect IRQL.
Current IRQL	Pool type	Address that the driver tried to free	0x31	A driver attempted to free pool at an incorrect IRQL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
Address that the driver tried to free	Address where one bit is corrupted	Reserved	0x32	A driver freed an address, but nearby bytes within the same page have a single bit error.

The _POOL_TYPE codes are enumerated in ntddk.h. In particular, zero indicates nonpaged pool and one indicates paged pool.

Cause

A driver has written to an invalid section of the special pool.

Resolution

Obtain a backtrace of the current thread. This backtrace will usually reveal the source of the error.

For information about the special pool, consult the Driver Verifier section of the Windows Driver Kit.

(Developer Content) Bug Check 0xC2: BAD_POOL_CALLER

5/26/2017 • 4 min to read • [Edit Online](#)

The BAD_POOL_CALLER bug check has a value of 0x000000C2. This indicates that the current thread is making a bad pool request.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BAD_POOL_CALLER Parameters

Parameter 1 indicates the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x00	0	Pool type	Pool tag	The current thread requested a zero-byte pool allocation.
0x01, 0x02, 0x04	Pointer to pool header	First part of pool header contents	0	The pool header has been corrupted.
0x06	Reserved	Pointer to pool header	Pool header contents	The current thread attempted to free the pool, which was already freed.
0x07	Reserved	Pool header contents	Address of the block of pool being freed	The current thread attempted to free the pool, which was already freed.
0x08	Current IRQL	Pool type	Size of allocation, in bytes	The current thread attempted to allocate the pool at an invalid IRQL.
0x09	Current IRQL	Pool type	Address of pool	The current thread attempted to free the pool at an invalid IRQL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xA	Address of pool	Allocator's tag	Tag being used in the attempted free	The current thread attempted to free pool memory by using the wrong tag. (The memory might belong to another component.)
0xB, 0xC, or 0xD	Address of pool	Pool allocation's tag	Bad quota process pointer	The current thread attempted to release a quota on a corrupted pool allocation.
0x40	Starting address	Start of system address space	0	The current thread attempted to free the kernel pool at a user-mode address.
0x41	Starting address	Physical page frame	Highest physical page frame	The current thread attempted to free a non-allocated nonpaged pool address.
0x42 or 0x43	Address being freed	0	0	The current thread attempted to free a virtual address that was never in any pool.
0x44	Starting address	Reserved	0	The current thread attempted to free a non-allocated nonpaged pool address.
0x46	Starting address	0	0	The current thread attempted to free an invalid pool address.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x47	Starting address	Physical page frame	Highest physical page frame	The current thread attempted to free a non-allocated nonpaged pool address.
0x48	Starting address	Reserved	Reserved	The current thread attempted to free a non-allocated paged pool address.
0x50	Starting address	Start offset, in pages, from beginning of paged pool	Size of paged pool, in bytes	The current thread attempted to free a non-allocated paged pool address.
0x60	Starting address	0	0	The current thread attempted to free an invalid contiguous memory address. (The caller of MmFreeContiguousMemory is passing a bad pointer.)
0x99	Address that is being freed	0	0	The current thread attempted to free pool with an invalid address. (This code can also indicate corruption in the pool header.)
0x9A	Pool type	Number of bytes requested	Pool tag	The current thread marked an allocation request MUST_SUCCEED . (This pool type is no longer supported.)

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x9B	Pool type	Number of bytes requested	Caller's address	<p>The current thread attempted to allocate a pool with a tag of 0 (This would be untrackable, and possibly corrupt the existing tag tables.)</p>
0x9C	Pool type	Number of bytes requested	Caller's address	<p>The current thread attempted to allocate a pool with a tag of "BIG". (This would be untrackable and could possibly corrupt the existing tag tables.)</p>
0x9D	Incorrect pool tag used	Pool type	Caller's address	The current thread attempted to allocate a pool with a tag that does not contain any letters or digits. Using such tags makes tracking pool issues difficult.
0x41286	Reserved	Reserved	Start offset from the beginning of the paged pool, in pages	The current thread attempted to free a paged pool address in the middle of an allocation.

The _POOL_TYPE codes are enumerated in Ntddk.h. In particular, 0 indicates nonpaged pool and 1 indicates paged pool.

Cause

An invalid pool request has been made by the current thread. Typically this is at a bad IRQL level or double freeing the same memory allocation, etc.

Resolution

Activate Driver Verifier with memory pool options enabled, to obtain more information about these errors and to locate the faulting driver.

Driver Verifier

Driver Verifier is a tool that runs in real time to examine the behavior of drivers. If it sees errors in the execution of driver code, it proactively creates an exception to allow that part of the driver code to be further scrutinized. The driver verifier manager is built into Windows and is available on all Windows PCs. To start the driver verifier manager, type *Verifier* at a command prompt. You can configure which drivers you would like to verify. The code that verifies drivers adds overhead as it runs, so try and verify the smallest number of drivers as possible. For more information, see [Driver Verifier](#).

Windows Memory Diagnostics

In particular, for situations with memory pool corruption, run the Windows Memory Diagnostics tool, to try and isolate the physical memory as a cause. In the control panel search box, type Memory, and then click **Diagnose your computer's memory problems**. After the test is run, use Event viewer to view the results under the System log. Look for the *MemoryDiagnostics-Results* entry to view the results.

Bug Check 0xC4: DRIVER_VERIFIER_DETECTED_VIOLATION

5/26/2017 • 39 min to read • [Edit Online](#)

The DRIVER_VERIFIER_DETECTED_VIOLATION bug check has a value of 0x000000C4. This is the general bug check code for fatal errors found by Driver Verifier. For more information, see [Handling a Bug Check When Driver Verifier is Enabled](#).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_VERIFIER_DETECTED_VIOLATION Parameters

Parameter 1 identifies the type of violation. The meaning of the remaining parameters varies with the value of Parameter 1. The parameter values are described in the following table.

Note If you have trouble viewing all 5 columns in this table, try the following:

- Expand your browser window to full size.
- Place the cursor in the table and use the arrow keys to scroll left and right.
- Or use the [MSDN Library version](#) of this page.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x00	Current IRQL	Pool type	0	The driver requested a zero-byte pool allocation.
0x01	Current IRQL	Pool type	Size of allocation, in bytes	The driver attempted to allocate paged memory with IRQL > APC_LEVEL.
0x02	Current IRQL	Pool type	Size of allocation, in bytes	The driver attempted to allocate nonpaged memory with IRQL > DISPATCH_LEVEL.
0x10	Bad Address	0	0	The driver attempted to free an address that was not returned from an allocate call.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x11	Current IRQL	Pool type	Address of pool	The driver attempted to free paged pool with IRQL > APC_LEVEL.
0x12	Current IRQL	Pool type	Address of pool	The driver attempted to free nonpaged pool with IRQL > DISPATCH_LEVEL.
0x13 or 0x14	Reserved	Pointer to pool header	Pool header contents	The driver attempted to free memory pool which was already freed.
0x16	Reserved	Pool address	0	The driver attempted to free pool at a bad address, or the driver passed invalid parameters to a memory routine.
0x30	Current IRQL	Requested IRQL	0	<p>The driver passed an invalid parameter to KeRaiseIrql.</p> <p>(The parameter was either a value lower than the current IRQL, or a value higher than HIGH_LEVEL. This may be the result of using an uninitialized parameter.)</p>

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x31	Current IRQL	Requested IRQL	0: New IRQL is bad 1: New IRQL is invalid inside a DPC routine	The driver passed an invalid parameter to KeLowerIrql . (The parameter was either a value higher than the current IRQL, or a value higher than HIGH_LEVEL. This may be the result of using an uninitialized parameter.)
0x32	Current IRQL	Spin lock address	0	The driver called KeReleaseSpinLock at an IRQL other than DISPATCH_LEVEL. (This may be due to a double-release of a spin lock.)
0x33	Current IRQL	Fast mutex address	0	The driver attempted to acquire fast mutex with IRQL > APC_LEVEL.
0x34	Current IRQL	Fast mutex address	0	The driver attempted to release fast mutex at an IRQL other than APC_LEVEL.
0x35	Current IRQL	Spin lock address	Old IRQL	The kernel released a spin lock with IRQL not equal to DISPATCH_LEVEL.
0x36	Current IRQL	Spin lock number	Old IRQL	The kernel released a queued spin lock with IRQL not equal to DISPATCH_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x37	Current IRQL	Thread APC disable count	Resource	The driver tried to acquire a resource, but APCs are not disabled.
0x38	Current IRQL	Thread APC disable count	Resource	The driver tried to release a resource, but APCs are not disabled.
0x39	Current IRQL	Thread APC disable count	Mutex	The driver tried to acquire a mutex "unsafe" with IRQL not equal to APC_LEVEL on entry.
0x3A	Current IRQL	Thread APC disable count	Mutex	The driver tried to release a mutex "unsafe" with IRQL not equal to APC_LEVEL on entry.
0x3C	Handle passed to routine	Object type	0	The driver called ObReferenceObjectByHandle with a bad handle.
0x3D	0	0	Address of the bad resource	The driver passed a bad (unaligned) resource to ExAcquireResourceExclusive .
0x3E	0	0	0	The driver called KeLeaveCriticalSection for a thread that is not currently in a critical region.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x3F	Object address	<p>New object reference count.</p> <p>-1: dereference case</p> <p>1: reference case</p>	0	The driver applied ObReferenceObject to an object that has a reference count of zero, or the driver applied ObDereferenceObject to an object that has a reference count of zero.
0x40	Current IRQL	Spin lock address	0	The driver called KeAcquireSpinLockAtDpcLevel with IRQL < DISPATCH_LEVEL.
0x41	Current IRQL	Spin lock address	0	The driver called KeReleaseSpinLockFromDpcLevel with IRQL < DISPATCH_LEVEL.
0x42	Current IRQL	Spin lock address	0	The driver called KeAcquireSpinLock with IRQL > DISPATCH_LEVEL.
0x51	Base address of allocation	Address of the reference beyond the allocation	Number of charged bytes	The driver attempted to free memory after having written past the end of the allocation. A bug check with this parameter occurs only when the Pool Tracking option of Driver Verifier is active.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x52	Base address of allocation	Reserved	Number of charged bytes	The driver attempted to free memory after having written past the end of the allocation. A bug check with this parameter occurs only when the Pool Tracking option of Driver Verifier is active.
0x53, 0x54, or 0x59	Base address of allocation	Reserved	Reserved	The driver attempted to free memory after having written past the end of the allocation. A bug check with this parameter occurs only when the Pool Tracking option of Driver Verifier is active.
0x60	Bytes allocated from paged pool	Bytes allocated from nonpaged pool	Total number of allocations that were not freed	The driver is unloading without first freeing its pool allocations. A bug check with this parameter occurs only when the Pool Tracking option of Driver Verifier is active.
0x61	Bytes allocated from paged pool	Bytes allocated from nonpaged pool	Total number of allocations that were not freed	A driver thread is attempting to allocate pool memory while the driver is unloading. A bug check with this parameter occurs only when the Pool Tracking option of Driver Verifier is active.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x62	Name of the driver	Reserved	Total number of allocations that were not freed, including both paged and nonpaged pool	The driver is unloading without first freeing its pool allocations. A bug check with this parameter occurs only when the Pool Tracking option of Driver Verifier is active.
0x70	Current IRQL	MDL address	Access mode	The driver called MmProbeAndLockPages with IRQL > DISPATCH_LEVEL.
0x71	Current IRQL	MDL address	Process address	The driver called MmProbeAndLockProcessPages with IRQL > DISPATCH_LEVEL.
0x72	Current IRQL	MDL address	Process address	The driver called MmProbeAndLockSelectedPages with IRQL > DISPATCH_LEVEL.
0x73	Current IRQL	In 32-bit Windows: Low 32 bits of the physical address In 64-bit Windows: the 64-bit physical address	Number of bytes	The driver called MmMapIoSpace with IRQL > DISPATCH_LEVEL.
0x74	Current IRQL	MDL address	Access mode	The driver called MmMapLockedPages in kernel mode with IRQL > DISPATCH_LEVEL.
0x75	Current IRQL	MDL address	Access mode	The driver called MmMapLockedPages in user mode with IRQL > APC_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x76	Current IRQL	MDL address	Access mode	The driver called MmMapLockedPagesSpecifyCache in kernel mode with IRQL > DISPATCH_LEVEL.
0x77	Current IRQL	MDL address	Access mode	The driver called MmMapLockedPagesSpecifyCache in user mode with IRQL > APC_LEVEL.
0x78	Current IRQL	MDL address	0	The driver called MmUnlockPages with IRQL > DISPATCH_LEVEL.
0x79	Current IRQL	Virtual address being unmapped	MDL address	The driver called MmUnmapLockedPages in kernel mode with IRQL > DISPATCH_LEVEL.
0x7A	Current IRQL	Virtual address being unmapped	MDL address	The driver called MmUnmapLockedPages in user mode with IRQL > APC_LEVEL.
0x7B	Current IRQL	Virtual address being unmapped	Number of bytes	The driver called MmUnmapIoSpace with IRQL > APC_LEVEL.
0x7C	MDL address	MDL flags	0	The driver called MmUnlockPages , and passed an MDL whose pages were never successfully locked.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x7D	MDL address	MDL flags	0	<p>The driver called MmUnlockPages, and passed an MDL whose pages are from nonpaged pool.</p> <p>(These should never be unlocked.)</p>
0x7E	Current IRQL	DISPATCH_LEVEL	0	<p>The driver called MmAllocatePagesForMdl, MmAllocatePagesForMdlEx, or MmFreePagesFromMdl with IRQL > DISPATCH_LEVEL.</p>
0x7F	Current IRQL	MDL address	MDL flags	<p>The driver called BuildMdlForNonPagedPool and passed an MDL whose pages are from paged pool.</p>
0x80	Current IRQL	Event address	0	<p>The driver called KeSetEvent with IRQL > DISPATCH_LEVEL.</p>
0x81	MDL address	MDL flags	0	<p>The driver called MmMapLockedPages.</p> <p>(You should use MmMapLockedPagesSpecifyCache instead, with the <i>BugCheckOnFailure</i> parameter set to FALSE.)</p>

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x82	MDL address	MDL flags	0	<p>The driver called MmMapLockedPagesSpecifyCache with the <i>BugCheckOnFailure</i> parameter equal to TRUE.</p> <p>(This parameter should be set to FALSE.)</p>
0x83	Start of physical address range to map	Number of bytes to map	First page frame number that isn't locked down	The driver called MmMaploSpace without having locked down the MDL pages. The physical pages represented by the physical address range being mapped must have been locked down prior to making this call.
0x85	MDL address	Number of pages to map	First page frame number that isn't locked down	The driver called MmMapLockedPages without having locked down the MDL pages.
0x89	MDL address	Pointer to the non-memory page in the MDL	The non-memory page number in the MDL	An MDL is not marked as "I/O", but it contains non-memory page addresses.
0x91	Reserved	Reserved	Reserved	<p>The driver switched stacks using a method that is not supported by the operating system.</p> <p>The only supported way to extend a kernel mode stack is by using KeExpandKernelStackAndCallout.</p>

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xA0 (Windows Server 2003 and later operating systems only)	Pointer to the IRP making the read or write request	Device object of the lower device	Number of the sector in which the error was detected	A cyclic redundancy check (CRC) error was detected on a hard disk. A bug check with this parameter occurs only when the Disk Integrity Checking option of Driver Verifier is active.
0xA1 (Windows Server 2003 and later operating systems only)	Copy of the IRP making the read or write request. (The actual IRP has been completed.)	Device object of the lower device	Number of the sector in which the error was detected	A CRC error was detected on a sector (asynchronously). A bug check with this parameter occurs only when the Disk Integrity Checking option of Driver Verifier is active.
0xA2 (Windows Server 2003 and later operating systems only)	IRP making the read or write request, or a copy of this IRP	Device object of the lower device	Number of the sector in which the error was detected	The CRCDISK checksum copies don't match. This could be a paging error. A bug check with this parameter occurs only when the Disk Integrity Checking option of Driver Verifier is active.
0xB0 (Windows Vista and later operating systems only)	MDL address	MDL flags	Incorrect MDL flags	The driver called MmProbeAndLockPages for an MDL with incorrect flags. For example, the driver passed an MDL created by MmBuildMdlForNonPagedPool to MmProbeAndLockPages .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xB1 (Windows Vista and later operating systems only)	MDL address	MDL flags	Incorrect MDL flags	The driver called MmProbeAndLockProcessPages for an MDL with incorrect flags. For example, the driver passed an MDL created by MmBuildMdlForNonPagedPool to MmProbeAndLockProcessPages .
0xB2 (Windows Vista and later operating systems only)	MDL address	MDL flags	Incorrect MDL flags	The driver called MmMapLockedPages for an MDL with incorrect flags. For example, the driver passed an MDL that is already mapped to a system address or that was not locked to MmMapLockedPages .
0xB3 (Windows Vista and later operating systems only)	MDL address	MDL flags	Missing MDL flags (at least one was expected)	The driver called MmMapLockedPages for an MDL with incorrect flags. For example, the driver passed an MDL that is not locked to MmMapLockedPages .
0xB4 (Windows Vista and later operating systems only)	MDL address	MDL flags	Unexpected partial MDL flag	The driver called MmUnlockPages for a partial MDL. A partial MDL is one that was created by IoBuildPartialMdl .
0xC0 (Windows Vista and later operating systems only)	Address of the IRP	Reserved	Reserved	The driver called IoCallDriver with interrupts disabled.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xC1 (Windows Vista and later operating systems only)	Address of the driver dispatch routine	Reserved	Reserved	A driver dispatch routine was returned with interrupts disabled.
0xC2 (Windows Vista and later operating systems only)	Reserved	Reserved	Reserved	The driver called a Fast I/O dispatch routine after interrupts were disabled.
0xC3 (Windows Vista and later operating systems only)	Address of the driver Fast I/O dispatch routine	Reserved	Reserved	A driver Fast I/O dispatch routine was returned with interrupts disabled.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xC5 (Windows Vista and later operating systems only)	Address of the driver dispatch routine	The current thread's APC disable count	The thread's APC disable count prior to calling the driver dispatch routine	<p>A driver dispatch routine has changed the thread's APC disable count.</p> <p>The APC disable count is decremented each time a driver calls KeEnterCriticalRegion, FsRtlEnterFileSystem, or acquires a mutex.</p> <p>The APC disable count is incremented each time a driver calls KeLeaveCriticalRegion, KeReleaseMutex, or FsRtlExitFileSystem.</p> <p>Because these calls should always be in pairs, the APC disable count should be zero whenever a thread is exited. A negative value indicates that a driver has disabled APC calls without re-enabling them. A positive value indicates that the reverse is true.</p>

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xC6 (Windows Vista and later operating systems only)	Address of the driver Fast I/O dispatch routine	Current thread's APC disable count	The thread's APC disable count prior to calling the Fast I/O driver dispatch routine	<p>A driver Fast I/O dispatch routine has changed the thread's APC disable count.</p> <p>The APC disable count is decremented each time a driver calls KeEnterCriticalRegion, FsRtlEnterFileSystem, or acquires a mutex.</p> <p>The APC disable count is incremented each time a driver calls KeLeaveCriticalRegion, KeReleaseMutex, or FsRtlExitFileSystem.</p> <p>Because these calls should always be in pairs, the APC disable count should be zero whenever a thread is exited. A negative value indicates that a driver has disabled APC calls without re-enabling them. A positive value indicates that the reverse is true.</p>
0xCA (Windows Vista and later operating systems only)	Address of the lookaside list	Reserved	Reserved	The driver has attempted to re-initialize a lookaside list.
0xCB (Windows Vista and later operating systems only)	Address of the lookaside list	Reserved	Reserved	The driver has attempted to delete an uninitialized lookaside list.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xCC (Windows Vista and later operating systems only)	Address of the lookaside list	Starting address of the pool allocation	Size of the pool allocation	The driver has attempted to free a pool allocation that contains an active lookaside list.
0xCD (Windows Vista and later operating systems only)	Address of the lookaside list	Block size specified by the caller	Minimum supported block size	The driver has attempted to create a lookaside list with an allocation block size that is too small.
0xD0 (Windows Vista and later operating systems only)	Address of the ERESOURCE structure	Reserved	Reserved	The driver has attempted to re-initialize an ERESOURCE structure.
0xD1 (Windows Vista and later operating systems only)	Address of the ERESOURCE structure	Reserved	Reserved	The driver has attempted to delete an uninitialized ERESOURCE structure.
0xD2 (Windows Vista and later operating systems only)	Address of the ERESOURCE structure	Starting address of the pool allocation	Size of the pool allocation	The driver has attempted to free a pool allocation that contains an active ERESOURCE structure.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xD5 (Windows Vista and later operating systems only)	Address of the IO_REMOVE_LOC K structure created by the checked build version of the driver	Current IoReleaseRemo veLock tag	Reserved	The current IoReleaseRemo veLock tag does not match the previous IoAcquireRemo veLock tag. If the driver calling IoReleaseRemo veLock is not in a checked build, Parameter 2 is the address of the shadow IO_REMOVE_LOC K structure created by Driver Verifier on behalf of the driver. In this case, the address of the IO_REMOVE_LOC K structure used by the driver is not used at all, because Driver Verifier is replacing the lock address for all the remove lock APIs. A bug check with this parameter occurs only when the I/O Verification option of Driver Verifier is active.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xD6 (Windows Vista and later operating systems only)	Address of the IO_REMOVE_LOC K structure created by the checked build version of the driver	Tag that does not match previous IoAcquireRemoteLock tag	Previous IoAcquireRemoteLock tag	The current IoReleaseRemoteLockAndWait tag does not match the previous IoAcquireRemoteLock tag. If the driver calling IoReleaseRemoteLock is not a checked build, Parameter 2 is the address of the shadow IO_REMOVE_LOC K structure created by Driver Verifier on behalf of the driver. In this case, the address of the IO_REMOVE_LOC K structure used by the driver is not used at all, because Driver Verifier is replacing the lock address for all the remove lock APIs. A bug check with this parameter occurs only when the I/O Verification option of Driver Verifier is active.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xD7 (Windows 7 operating systems and later only)	Address of the checked build Remove Lock structure that is used internally by Driver Verifier	Address of the Remove Lock structure that is specified by the driver	Reserved	A Remove Lock cannot be re-initialized, even after it calls IoReleaseRemoveLockAndWait , because other threads might still be using that lock (by calling IoAcquireRemoveLock). The driver should allocate the Remove Lock inside its device extension, and initialize it a single time. The lock will be deleted together with the device extension.
0xDA (Windows Vista and later operating systems only)	Starting address of the driver	WMI callback address inside the driver	Reserved	An attempt was made to unload a driver that has not deregistered its WMI callback function.
0xDB (Windows Vista and later operating systems only)	Address of the device object	Reserved	Reserved	An attempt was made to delete a device object that was not deregistered from WMI.
0xDC (Windows Vista and later operating systems only)	Reserved	Reserved	Reserved	An invalid RegHandle value was specified as a parameter of the function EtwUnregister .
0xDD (Windows Vista and later operating systems only)	Address of the call to EtwRegister	Starting address of the unloading driver	For Windows 8/Windows 8 and later versions, this parameter is the ETW RegHandle value.	An attempt was made to unload a driver without calling EtwUnregister .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xDF (Windows 7 operating systems and later only)	Synchronization object address			The synchronization object is in session address space. Synchronization objects are not allowed in session address space because they can be manipulated from another session or from system threads that have no session virtual address space.
0xE0 (Windows Vista and later operating systems only)	User-mode address that is used as a parameter	Size ,in bytes, of the address range that is used as a parameter	Reserved	A call was made to an operating system kernel function that specified a user-mode address as a parameter.
0xE1 (Windows Vista and later operating systems only)	Address of the synchronization object	Reserved	Reserved	A synchronization object was found to have an address that was either invalid or pageable.
0xE2 (Windows Vista and later operating systems only)	Address of the IRP	User-mode address present in the IRP	Reserved	An IRP with Irp->RequestorMode set to KernelMode was found to have a user-mode address as one of its members.
0xE3 (Windows Vista and later operating systems only)	Address of the call to the API	User-mode address used as a parameter in the API	Reserved	A driver has made a call to a kernel-mode ZwXxx routine with a user-mode address as a parameter.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xE4 (Windows Vista and later operating systems only)	Address of the call to the API	Address of the malformed UNICODE_STRING structure	Reserved	A driver has made a call to a kernel-mode ZwXxx routine with a malformed UNICODE_STRING structure as a parameter.
0xE5 (Windows Vista and later operating systems only)	Current IRQL	Reserved	Reserved	A call was made to a Kernel API at the incorrect IRQL.
0xEA (Windows Vista and later operating systems only)	Current IRQL	The thread's APC disable count	Address of the pushlock	A driver has attempted to acquire a pushlock while APCs are enabled.
0xEB (Windows Vista and later operating systems only)	Current IRQL	The thread's APC disable count	Address of the pushlock	A driver has attempted to release a pushlock while APCs are enabled.
0xF0 (Windows Vista and later operating systems only)	Address of the destination buffer	Address of the source buffer	Number of bytes to copy	A driver called the <code>memcpy</code> function with overlapping source and destination buffers.
0xF5 (Windows Vista and later operating systems only)	Address of the NULL handle	Object type	Reserved	A driver passed a NULL handle to ObReferenceObjectByHandle .
0xF6 (Windows 7 operating systems and later)	Handle value being referenced	Address of the current process	Address inside the driver that performs the incorrect reference	A driver references a user-mode handle as kernel mode.
0xF7 (Windows 7 operating systems and later)	Handle value specified by the caller	Object type specified by the caller	AccessMode specified by the caller	A driver is attempting a user-mode reference for a kernel handle in the context of the system process.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xFA (Windows 7 operating systems and later)	Completion routine address.	IRQL value before it calls the completion routine	Current IRQL value, after it calls the completion routine	The IRP completion routine returned at an IRQL that was different from the IRQL the routine was called at.
0xFB (Windows 7 operating systems and later)	Completion routine address	Current thread's APC disable count	The thread's APC disable count before it calls the IRP completion routine	<p>The thread's APC disable count was changed by the driver's IRP completion routine.</p> <p>The APC disable count is decremented each time a driver calls KeEnterCriticalRegion, FsRtlEnterFileSystem, or acquires a mutex.</p> <p>The APC disable count is incremented each time a driver calls KeLeaveCriticalRegion, KeReleaseMutex, or FsRtlExitFileSystem.</p> <p>Because these calls should always be in pairs, the APC disable count should be zero whenever a thread is exited. A negative value indicates that a driver has disabled APC calls without re-enabling them. A positive value indicates that the reverse is true.</p>

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x105 (Windows 7 operating systems and later)	Address of the IRP			The driver uses ExFreePool instead of IoFreeIrp to release the IRP.
0x10A (Windows 7 operating systems and later)				The driver attempts to charge pool quota to the Idle process.
0x10B (Windows 7 operating systems and later)				The driver attempts to charge pool quota from a DPC routine. This is incorrect because the current process context is undefined.
0x110 (Windows 7 operating systems and later)	Address of the Interrupt Service Routine	Address of the extended context that was saved before it executed the ISR	Address of the extended context was saved after it executed the ISR	The interrupt service routine (ISR) for the driver has corrupted the extended thread context.
0x115 (Windows 7 operating systems and later)	The address of the thread that is responsible for the shutdown, which might be deadlocked			Driver Verifier detected that the system has taken longer than 20 minutes and shutdown is not complete.
0x11A (Windows 7 operating systems and later)	Current IRQL			The driver calls KeEnterCriticalRegion at IRQL > APC_LEVEL.
0x11B (Windows 7 operating systems and later)	Current IRQL			The driver calls KeLeaveCriticalRegion at IRQL > APC_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x120 (Windows 7 operating systems and later)	Address of the IRQL value	Address of the Object to wait on	Address of Timeout value	The thread waits at IRQL > DISPATCH_LEVEL. Callers of KeWaitForSingleObject or KeWaitForMultipleObjects must run at IRQL <= DISPATCH_LEVEL.
0x121 (Windows 7 operating systems and later)	Address of the IRQL value	Address of the Object to wait on	Address of Timeout value	The thread waits at IRQL equals DISPATCH_LEVEL and the Timeout is NULL . Callers of KeWaitForSingleObject or KeWaitForMultipleObjects can run at IRQL <= DISPATCH_LEVEL. If a NULL pointer is supplied for Timeout, the calling thread remains in a wait state until the Object is signaled.
0x122 (Windows 7 operating systems and later)	Address of the IRQL value	Address of the Object to wait on	Address of the Timeout value	The thread waits at DISPATCH_LEVEL and Timeout value is not equal to zero (0). If the Timeout != 0, the callers of KeWaitForSingleObject or KeWaitForMultipleObjects must run at IRQL <= APC_LEVEL.
0x123 (Windows 7 operating systems and later)	Address of the Object to wait on			The caller of KeWaitForSingleObject or KeWaitForMultipleObjects specified the wait as UserMode , but the Object is on the kernel stack.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x130 (Windows 7 operating systems and later)	Address of work item			The work item is in session address space. Work items are not allowed in session address space because they can be manipulated from another session or from system threads that have no session virtual address space.
0x131 (Windows 7 operating systems and later)	Address of work item			The work item is in pageable memory. Work items have to be in nonpageable memory because the kernel uses them at DISPATCH_LEVEL.
0x135	Address of IRP	Number of milliseconds allowed between the IoCancelIrp call and the completion for this IRP		The canceled IRP did not completed in the expected time The driver took longer than expected to complete the canceled IRP.
0x13A	Address of the pool block being freed	Incorrect value	Address of the incorrect value	The driver has called ExFreePool and Driver Verifier detects an error in one of the internal values that is used to track pool usage.
0x13B	Address of the pool block being freed	Address of the incorrect value	Address of a pointer to the incorrect memory page	The driver has called ExFreePool and Driver Verifier detects an error in one of the internal values that is used to track pool usage.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x13C	Address of the pool block being freed	Incorrect value	Address of the incorrect value	The driver has called ExFreePool and Driver Verifier detects an error in one of the internal values that is used to track pool usage.
0x13D	Address of the pool block being freed	Address of the incorrect value	Correct value that was expected	The driver has called ExFreePool and Driver Verifier detects an error in one of the internal values that is used to track pool usage.
0x13E	Pool block address specified by the caller	Pool block address tracked by Driver Verifier	Pointer to the pool block address that is tracked by Driver Verifier	The pool block address specified by the caller of ExFreePool is different from the address tracked by Driver Verifier.
0x13F	Address of the pool block being freed	Number of bytes being freed	Pointer to the number of bytes tracked by Driver Verifier	The number of bytes of memory being freed in the call to ExFreePool is different from the number of bytes tracked by Driver Verifier.
0x1000 (Windows XP and later operating systems only)	Address of the resource	Reserved	Reserved	Self-deadlock: The current thread has tried to recursively acquire a resource. A bug check with this parameter occurs only when the Deadlock Detection option of Driver Verifier is active.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1001 (Windows XP and later operating systems only)	Address of the resource that was the final cause of the deadlock	Reserved	Reserved	<p>Deadlock: A lock hierarchy violation has been found. A bug check with this parameter occurs only when the Deadlock Detection option of Driver Verifier is active.</p> <p>(Use the !deadlock extension for further information.)</p>
0x1002 (Windows XP and later operating systems only)	Address of the resource	Reserved	Reserved	<p>Uninitialized resource: A resource has been acquired without having been initialized first. A bug check with this parameter occurs only when the Deadlock Detection option of Driver Verifier is active.</p>
0x1003 (Windows XP and later operating systems only)	Address of the resource that is being released deadlocked	Address of the resource that should have been released first	Reserved	<p>Unexpected release: A resource has been released in an incorrect order. A bug check with this parameter occurs only when the Deadlock Detection option of Driver Verifier is active.</p>

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1004 (Windows XP and later operating systems only)	Address of the resource	Address of the thread that acquired the resource	Address of the current thread	Unexpected thread: The wrong thread releases a resource. A bug check with this parameter occurs only when the Deadlock Detection option of Driver Verifier is active.
0x1005 (Windows XP and later operating systems only)	Address of the resource	Reserved	Reserved	Multiple initialization: A resource is initialized more than one time. A bug check with this parameter occurs only when the Deadlock Detection option of Driver Verifier is active.
0x1007 (Windows XP and later operating systems only)	Address of the resource	Reserved	Reserved	Unacquired resource: A resource is released before it has been acquired. A bug check with this parameter occurs only when the Deadlock Detection option of Driver Verifier is active.
0x1008 (Windows 7 operating systems and later)	Lock address	Driver Verifier internal data	Driver Verifier internal data	The driver tried to acquire a lock by using an API that is mismatched for this lock type.
0x1009 (Windows 7 operating systems and later)	Lock address	Driver Verifier internal data	Driver Verifier internal data	The driver tried to release a lock by using an API that is mismatched for this lock type.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x100A (Windows 7 operating systems and later)	Owner thread address	Driver Verifier internal data		The terminated thread owns the lock.
0x100B (Windows 7 operating systems and later)	Lock address	Owner thread address	Driver Verifier internal address	The deleted lock is still owned by a thread.
0xA001 (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	A pointer to the virtual switch object (if NON-NULL)	Reserved (unused)	VM Switch: The SourceHandle for the caller-supplied <i>NetBufferList</i> must be set. See the AllocateNetBufferListForwardingContext routine.
0xA002 (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	A pointer to the virtual switch object (if NON-NULL).	Reserved (unused)	VM Switch: The caller supplied <i>NetBufferList</i> 's forwarding detail is not zero. See the AllocateNetBufferListForwardingContext routine.
0xA003 (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	A pointer to the virtual switch object (if NON-NULL).	Reserved (unused)	VM Switch: The caller supplied a <i>NetBufferList</i> with packet header or routing context that is NULL. See Packet Management Guidelines for the Extensible Switch Data Path .
0xA004 (Windows 8.1 operating systems and later)	ID of invalid port	NIC Index	A pointer to the virtual switch object (if NON-NULL).	VM Switch: The caller specified an invalid Port and NIC index combination. See Hyper-V Extensible Switch Port and Network Adapter States .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xA005 (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	A pointer to the Destination list.	A pointer to the virtual switch object (if NON-NULL).	VM Switch: The caller supplied an invalid destination. See AddNetBufferList Destination and UpdateNetBuffer ListDestinations .
0xA006 (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	A pointer to the virtual switch object (if NON-NULL).	Reserved (unused)	VM Switch: The caller supplied an invalid source NIC or Port object. See Hyper-V Extensible Switch Port and Network Adapter States .
0xA007 (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	A pointer to the virtual switch object (if NON-NULL).	Reserved (unused)	VM Switch: The caller supplied an invalid destination list. See AddNetBufferList Destination and UpdateNetBuffer ListDestinations .
0xA008 (Windows 8.1 operating systems and later)	Parent NIC object	NIC index	A pointer to the virtual switch object (if NON-NULL).	VM Switch: Attempting to reference a NIC when not allowed. See Hyper-V Extensible Switch Port and Network Adapter States .
0xA009 (Windows 8.1 operating systems and later)	Port being referenced	A pointer to the virtual switch object (if NON-NULL)	Reserved (unused)	VM Switch: Attempt to reference a port when not allowed. See Hyper-V Extensible Switch Port and Network Adapter States .
0xA00A (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	ContextTypeInfo object	Reserved (unused)	VM Switch: Failure context is already set. See SetNetBufferListSwitchContext .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0xA00B (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	NDIS_SWITCH_RE PORT_FILTERED_ NBL_FLAGS_*	A pointer to the virtual switch object (if NON-NULL)	VM Switch: Invalid direction provided for dropped <i>NetBufferList</i> . See ReportFilteredNetBufferLists .
0xA00C (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	Send Flags value	A pointer to the virtual switch object (if NON-NULL)	VM Switch: <i>NetBufferList</i> chain has multiple source ports when NDIS_SEND_FLAG S_SWITCH_SINGLE_SOURCE flag is set. See Hyper-V Extensible Switch Send and Receive Flags .
0xA00D (Windows 8.1 operating systems and later)	A pointer to the <i>NetBufferList</i> object	A pointer to the virtual switch context	A pointer to the virtual switch object (if NON-NULL)	VM Switch: One or more <i>NetBufferLists</i> in chain have invalid destination when NDIS_RECEIVE_FLAGS_SWITCH_DESTINATION_GRO_UP flag is set. See Hyper-V Extensible Switch Send and Receive Flags .
0x2000 (Windows 7 operating systems and later)	The first argument passed to the StorPortInitialize routine. This parameter is a pointer to the driver object that the operating system passed to the miniport driver in the first argument of the miniport driver's <i>DriverEntry</i> routine.	The second argument passed to the StorPortInitialize routine. This parameter is a pointer to context information that the operating system passed to the miniport driver in the second argument of the miniport driver's <i>DriverEntry</i> routine.	Reserved	The Storport miniport driver passed a bad argument (a NULL pointer) to the StorPortInitialize routine.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x00020002 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlApclte . The rule specifies that the driver must call ObGetObjectSecurity and ObReleaseObjectSecurity only when IRQL <= APC_LEVEL.
0x00020003 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlDispatch . The IrqlDispatch rule specifies that the driver must call certain routines only when IRQL = DISPATCH_LEVEL
0x00020004 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlExAllocatePool . The IrqlExAllocatePool rule specifies that the driver calls ExAllocatePoolWithTag and ExAllocatePoolWithTagPriority only when at IRQL<=DISPATCH_LEVEL.
0x00020005 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlExApclte1 . The IrqlExApclte1 rule specifies that the driver calls ExAcquireFastMutex and ExTryToAcquireFastMutex only at IRQL <= APC_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x00020006 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlExApclte2 . The IrqlExApclte2 rule specifies that the driver calls certain routines only when IRQL <= APC_LEVEL.
0x00020007 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlExApclte3 . The IrqlExApclte3 rule specifies that the driver must call certain executive support routines only when IRQL <= APC_LEVEL.
0x00020008 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlExPassive . The IrqlExPassive rule specifies that the driver must call certain executive support routines only when IRQL = PASSIVE_LEVEL.
0x00020009 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlIoApcLte . The IrqlIoApcLte rule specifies that the driver must call certain I/O manager routines only when IRQL <= APC_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0002000A (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlIoPassive1 . The IrqlIoPassive1 rule specifies that the driver must call certain I/O manager routines only when IRQL = PASSIVE_LEVEL.
0x0002000B (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlIoPassive2 . The IrqlIoPassive2 rule specifies that the driver must call certain I/O manager routines only when IRQL = PASSIVE_LEVEL.
0x0002000C (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlIoPassive3 . The IrqlIoPassive3 rule specifies that the driver must call certain I/O manager routines only when IRQL = PASSIVE_LEVEL.
0x0002000D (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlIoPassive4 . The IrqlIoPassive4 rule specifies that the driver must call certain I/O manager routines only when IRQL = PASSIVE_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0002000E (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlIoPassive5 . The IrqlIoPassive5 rule specifies that the driver must call certain I/O manager routines only when IRQL = PASSIVE_LEVEL.
0x0002000F (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlKeApcLte1 . The IrqlKeApcLte1 rule specifies that the driver must call certain kernel routines only when IRQL <= APC_LEVEL.
0x00020010 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlKeApcLte2 . The IrqlKeApcLte2 rule specifies that the driver must call certain kernel routines only when IRQL <= APC_LEVEL.
0x00020011 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlKeDispatchLte . The IrqlKeDispatchLte rule specifies that the driver must call certain kernel routines only when IRQL <= DISPATCH_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x00020015 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlKeReleaseSpinLock . The IrqlKeReleaseSpinLock rule specifies that the driver must call KeReleaseSpinLock only when IRQL = DISPATCH_LEVEL.
0x00020016 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlKeSetEvent . The IrqlKeSetEvent rule specifies that the KeSetEvent routine is only called at IRQL <= DISPATCH_LEVEL when Wait is set to FALSE, and at IRQL <= APC_LEVEL when Wait is set to TRUE.
0x00020019 (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlMmApcLte . The IrqlMmApcLte rule specifies that the driver must call certain memory manager routines only when IRQL <= APC_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0002001A (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlMmDispatch . The IrqlMmDispatch rule specifies that the driver must call MmFreeContiguousMemory only when IRQL = DISPATCH_LEVEL.
0x0002001B (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlObPassive . The IrqlObPassive rule specifies that the driver must call ObReferenceObjectByHandle only when IRQL = PASSIVE_LEVEL.
0x0002001C (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlPsPassive . The IrqlPsPassive rule specifies that the driver must call certain process and thread manager routines only when IRQL = PASSIVE_LEVEL.
0x0002001D (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule IrqlReturn .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0002001E (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlRtlPassive . The IrqlRtlPassive rule specifies that the driver must call RtlDeleteRegistryValue only when IRQL = PASSIVE_LEVEL.
0x0002001F (Windows 8 operating systems and later)	Pointer to the string that describes the violated rule condition.	Optional pointer to the rule state variable(s).	Reserved	The driver violated the DDI compliance rule IrqlZwPassive . The IrqlZwPassive rule specifies that the driver must call ZwClose only when IRQL = PASSIVE_LEVEL.
0x00020022 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Reserved (unused)	Reserved (unused)	The driver violated the DDI compliance rule IrqlIoDispatch .
0x00040003 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule CriticalRegions .
0x00040006 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule QueuedSpinLock .
0x00040007 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule QueuedSpinLockRelease .
0x00040009 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule SpinLock .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0004000B (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule SpinlockRelease .
0x0004000E (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule GuardedRegions .
0x0004100B (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Reserved	Reserved	The driver violated the DDI compliance rule RequestedPower .
0x0004100F (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule IoSetCompletionExCompleteIrp .
0x00043006 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Reserved	Reserved	The driver violated the DDI compliance rule PnpRemove .
0x00091001 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule NdisOidComplete .
0x00091002 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule NdisOidDoubleComplete .
0x0009100E (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the DDI compliance rule NdisOidDoubleRequest .

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x00092003 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule NdisTimedOidComplete .
0x0009200D (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule NdisTimedDataSend .
0x0009200F (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule NdisTimedDataHang .
0x00093004 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule WlanAssociation .
0x00093005 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule WlanConnectionRoaming .
0x00093006 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule WlanDisassociation .
0x00094007 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule WlanTimedAssociation .

0x00094009 (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule WlanTimedConnectionRequest .
0x0009400B (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule WlanTimedLinkQuality .
0x0009400C (Windows 8.1 operating systems and later)	Pointer to the string that describes the violated rule condition.	Address of internal rule state (second argument to !ruleinfo).	Address of supplemental states (third argument to !ruleinfo).	The driver violated the NDIS/WIFI verification rule WlanTimedScan .

Cause

See the description of each code in the Parameters section for a description of the cause. Further information can be obtained by using the [!analyze -v](#) extension.

Resolution

This bug check can only occur when Driver Verifier has been instructed to monitor one or more drivers. If you did not intend to use Driver Verifier, you should deactivate it. You might also consider removing the driver that caused this problem.

If you are the driver writer, use the information obtained through this bug check to fix the bugs in your code.

For full details on Driver Verifier, see the [Driver Verifier](#) section of the Windows Driver Kit (WDK).

Remarks

The _POOL_TYPE codes are enumerated in Ntddk.h. In particular, **0** (zero) indicates nonpaged pool and **1** (one) indicates paged pool.

(Windows 8 and later versions of Windows) If [DDI compliance checking](#) causes a bug check, run [Static Driver Verifier](#) on the driver source code and specify the DDI compliance rule (identified by the parameter 1 value) that caused the bug check. Static Driver Verifier can help you locate the cause of the problem in your source code.

Handling a Bug Check When Driver Verifier is Enabled

Bug Check 0xC5: DRIVER_CORRUPTED_EXPOOL

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_CORRUPTED_EXPOOL bug check has a value of 0x000000C5. This indicates that the system attempted to access invalid memory at a process IRQL that was too high.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_CORRUPTED_EXPOOL Parameters

PARAMETER	DESCRIPTION
1	Memory referenced
2	IRQL at time of reference
3	0: Read 1: Write
4	Address that referenced memory

Cause

The kernel attempted to access pageable memory (or perhaps completely invalid memory) when the IRQL was too high. The ultimate cause of this problem is almost certainly a driver that has corrupted the system pool.

In most cases, this bug check results if a driver corrupts a small allocation (less than PAGE_SIZE). Larger allocations result in [bug check 0xD0](#) (DRIVER_CORRUPTED_MMPOOL).

Resolution

If you have recently installed any new software, check to see if it is properly installed. Check for updated drivers on the manufacturer's website.

To debug this error, use the special pool option of Driver Verifier. If this fails to reveal the driver that caused the error, use the Global Flags utility to enable the special pool by pool tag.

For information about the special pool, consult the Driver Verifier section of the Windows Driver Kit.

Bug Check 0xC6: DRIVER_CAUGHT MODIFYING_FREED_POOL

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_CAUGHT MODIFYING_FREED_POOL bug check has a value of 0x000000C6. This indicates that the driver attempted to access a freed memory pool.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_CAUGHT MODIFYING_FREED_POOL Parameters

PARAMETER	DESCRIPTION
1	Memory referenced
2	0: Read 1: Write
3	0: Kernel mode 1: User mode
4	Reserved

Remarks

The faulty component will be displayed in the current kernel stack. This driver should be either replaced or debugged.

Bug Check 0xC7: TIMER_OR_DPC_INVALID

5/26/2017 • 2 min to read • [Edit Online](#)

The TIMER_OR_DPC_INVALID bug check has a value of 0x000000C7. This is issued if a kernel timer or delayed procedure call (DPC) is found somewhere in memory where it is not permitted.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

TIMER_OR_DPC_INVALID Parameters

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0	Address of the timer object	Start of memory range being checked	End of memory range being checked	The timer object was found in a block of memory where a timer object is not permitted. .
0x1	Address of the DPC object	Start of memory range being checked	End of memory range being checked	The DPC object was found in a block of memory where a DPC object is not permitted.
0x2	Address of the DPC routine	Start of memory range being checked	End of memory range being checked	The DPC routine was found in a block of memory where a DPC object is not permitted.
0x3	Address of the DPC object	Processor number	Number of processors in the system	The processor number for the DPC object is not correct.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x4	Address of the DPC routine	The thread's APC disable count before the kernel calls the DPC routine	The thread's APC disable count after the DPC routine is called	<p>The thread's APC disable count was changed during DPC routine execution.</p> <p>The APC disable count is decremented each time a driver calls KeEnterCriticalRegion, FsRtlEnterFileSystem, or acquires a mutex.</p> <p>The APC disable count is incremented each time a driver calls KeLeaveCriticalRegion, KeReleaseMutex, or FsRtlExitFileSystem.</p>
0x5	Address of the DPC routine	The thread's APC disable count before the kernel calls the DPC routine	The thread's APC disable count after the DPC routine is called	<p>The thread's APC disable count was changed during the execution of timer DPC routine.</p> <p>The APC disable count is decremented each time a driver calls KeEnterCriticalRegion, FsRtlEnterFileSystem, or acquires a mutex.</p> <p>The APC disable count is incremented each time a driver calls KeLeaveCriticalRegion, KeReleaseMutex, or FsRtlExitFileSystem.</p>

Cause

This condition is usually caused by a driver failing to cancel a timer or DPC before freeing the memory where it

resides.

Resolution

If you are the driver writer, use the information obtained through this bug check to fix the bugs in your code.

If you are a system administrator, you should unload the driver if the problem persists.

Bug Check 0xC8: IRQL_UNEXPECTED_VALUE

5/26/2017 • 1 min to read • [Edit Online](#)

The IRQL_UNEXPECTED_VALUE bug check has a value of 0x000000C8. This indicates that the processor's IRQL is not what it should be at this time.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

IRQL_UNEXPECTED_VALUE Parameters

PARAMETER	DESCRIPTION
1	The value of the following bit computation: $(\text{Current IRQL} \ll 16) \mid (\text{Expected IRQL} \ll 8) \mid \text{UniqueValue}$
2	Zero, or APC->KernelRoutine
3	Zero, or APC
4	Zero, or APC->NormalRoutine

You can determine "UniqueValue" by computing (Parameter 1 AND 0xFF). If "UniqueValue" is either zero or one, Parameter 2, Parameter 3, and Parameter 4 will equal the indicated APC pointers. Otherwise, these parameters will equal zero.

Cause

This error is usually caused by a device driver or another lower-level program that changed the IRQL for some period and did not restore the original IRQL at the end of that period. For example, the routine may have acquired a spin lock and failed to release it.

Bug Check 0xC9: DRIVER_VERIFIER_IOMANAGER_VIOLATION

5/26/2017 • 15 min to read • [Edit Online](#)

The DRIVER_VERIFIER_IOMANAGER_VIOLATION bug check has a value of 0x000000C9. This is the bug check code for all Driver Verifier **I/O Verification** violations.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_VERIFIER_IOMANAGER_VIOLATION Parameters

When Driver Verifier is active and **I/O Verification** is selected, various I/O violations will cause this bug check to be issued. Parameter 1 identifies the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x01	Address of IRP being freed	0	0	The driver attempted to free an object whose type is not IO_TYPE_IRP.
0x02	Address of IRP being freed	0	0	The driver attempted to free an IRP that is still associated with a thread.
0x03	Address of IRP being sent	0	0	The driver passed IoCallDriver an IRP Type not equal to IRP_TYPE.
0x04	Address of device object	0	0	The driver passed IoCallDriver an invalid device object.
0x05	Address of device object associated with offending driver	IRQL before IoCallDriver	IRQL after IoCallDriver	The IRQL changed during a call to the driver dispatch routine.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x06	IRP status	Address of IRP being completed	0	The driver called IoCompleteRequest with a status marked as pending (or equal to -1).
0x07	Address of cancel routine	Address of IRP being completed	0	The driver called IoCompleteRequest while its cancel routine was still set.
0x08	Address of device object	IRP major function code	Exception status code	The driver passed IoBuildAsynchronousFsdRequest an invalid buffer.
0x09	Address of device object	I/O control code	Exception status code	The driver passed IoBuildDeviceControlRequest an invalid buffer.
0x0A	Address of device object	0	0	The driver passed IoInitializeTimer a device object with an already-initialized timer.
0x0C	Address of I/O status block	0	0	The driver passed an I/O status block to an IRP, but this block is allocated on a stack which has already unwound past that point.
0x0D	Address of user event object	0	0	The driver passed a user event to an IRP, but this event is allocated on a stack which has already unwound past that point.
0x0E	Current IRQL	Address of IRP	0	The driver called IoCompleteRequest with IRQL > DISPATCH_LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0F	Address of the device object to which the IRP is being sent	Pointer to the IRP	Pointer to file object	The driver sent a create request with a file object that has been closed, or that had its open canceled.

In addition to the errors mentioned in the previous table, there are a number of **I/O Verification** errors that will cause Driver Verifier to halt the system, but which are not actually bug checks.

These errors cause messages to be displayed on the blue screen, in a crash dump file, and in a kernel debugger. These messages will appear differently in each of these locations. When these errors occur, the hexadecimal bug check code 0xC9 and the bug check string DRIVER_VERIFIER_IOMANAGER_VIOLATION do not appear on the blue screen or in the debugger, although they will appear in a crash dump file.

On the blue screen, the following data will be displayed:

- The message **IO SYSTEM VERIFICATION ERROR**.
- The message **WDM DRIVER ERROR XXX**, where XXX is a hexadecimal code representing the specific error. (See the table below for a list of the I/O error codes and their meanings.)
- The name of the driver which caused the error.
- The address in the driver's code where the error was detected (Parameter 2).
- A pointer to the IRP (Parameter 3).
- A pointer to the device object (Parameter 4).

If a kernel-mode crash dump has been enabled, the following information will appear in the crash dump file:

- The message **BugCheck 0xC9 (DRIVER_VERIFIER_IOMANAGER_VIOLATION)**.
- The hexadecimal I/O error code. (See the table below for a list of the I/O error codes and their meanings.)
- The address in the driver's code where the error was detected.
- A pointer to the IRP.
- A pointer to the device object.

If a kernel debugger is attached to the system which has caused this violation, the following information will be sent to the debugger:

- The message **WDM DRIVER ERROR**, along with an assessment of the severity of the error.
- The name of the driver which caused the error.
- A descriptive string which explains the cause of this error. Often additional information is passed along, such as a pointer to the IRP. (See the table below for a list of these descriptive strings and what additional information is specified.)
- A query for further action. Possible responses are **b** (break), **i** (ignore), **z** (zap), **r** (remove), or **d** (disable). Instructing the operating system to continue allows you to see what would happen "down the line" if this error had not occurred. Of course, this often will lead to additional bug checks. The "zap" option will actually remove the breakpoint that caused this error to be discovered.

Note No other bug checks can be ignored in this manner. Only this kind of **I/O Verification** errors can be ignored, and even these errors can only be ignored if a kernel debugger is attached.

The following table lists those **I/O Verification** errors that can appear.

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x200	Unknown	This code covers all unknown I/O Verification errors.
0x201	Fatal error	A device is deleting itself while there is another device beneath it in the driver stack. This may be because the caller has forgotten to call IoDetachDevice first, or the lower driver may have incorrectly deleted itself.
0x202	Fatal error	A driver has attempted to detach from a device object that is not attached to anything. This may occur if detach was called twice on the same device object. (Device object specified.)
0x203	Fatal error	A driver has called IoCallDriver without setting the cancel routine in the IRP to NULL . (IRP specified.)
0x204	Fatal error	The caller has passed in NULL as a device object. This is fatal. (IRP specified.)
0x205	Fatal error	The caller is forwarding an IRP that is currently queued beneath it. The code handling IRPs returning STATUS_PENDING in this driver appears to be broken. (IRP specified.)
0x206	Fatal error	The caller has incorrectly forwarded an IRP (control field not zeroed). The driver should use IoCopyCurrentIrpStackLocationToNext or IoSkipCurrentIrpStackLocation . (IRP specified.)
0x207	Fatal error	The caller has manually copied the stack and has inadvertently copied the upper layer's completion routine. The driver should use IoCopyCurrentIrpStackLocationToNext . (IRP specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x208	Fatal error	This IRP is about to run out of stack locations. Someone may have forwarded this IRP from another stack. (IRP specified.)
0x209	Fatal error	The caller is completing an IRP that is currently queued beneath it. The code handling IRPs returning STATUS_PENDING in this driver appears to be broken. (IRP specified.)
0x20A	Fatal error	The caller of IoFreeIrp is freeing an IRP that is still in use. (Original IRP and IRP in use specified.)
0x20B	Fatal error	The caller of IoFreeIrp is freeing an IRP that is still in use. (IRP specified.)
0x20C	Fatal error	The caller of IoFreeIrp is freeing an IRP that is still queued against a thread. (IRP specified.)
0x20D	Fatal error	The caller of IoInitializeIrp has passed an IRP that was allocated with IoAllocateIrp . This is illegal and unnecessary, and has caused a quota leak. Check the documentation for IoReuseIrp if this IRP is being recycled.
0x20E	Non-fatal error	A PNP IRP has an invalid status. (Any PNP IRP must have its status initialized to STATUS_NOT_SUPPORTED.) (IRP specified.)
0x20F	Non-fatal error	A Power IRP has an invalid status. (Any Power IRP must have its status initialized to STATUS_NOT_SUPPORTED.) (IRP specified.)
0x210	Non-fatal error	A WMI IRP has an invalid status. (Any WMI IRP must have its status initialized to STATUS_NOT_SUPPORTED.) (IRP specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x211	Non-fatal error	The caller has forwarded an IRP while skipping a device object in the stack. The caller is probably sending IRPs to the PDO instead of to the device returned by IoAttachDeviceToDeviceStack . (IRP specified.)
0x212	Non-fatal error	The caller has trashed or has not properly copied the IRP's stack. (IRP specified.)
0x213	Non-fatal error	The caller has changed the status field of an IRP it does not understand. (IRP specified.)
0x214	Non-fatal error	The caller has changed the information field of an IRP it does not understand. (IRP specified.)
0x215	Non-fatal error	A non-successful non-STATUS_NOT_SUPPORTED IRP status for IRP_MJ_PNP is being passed down stack. (IRP specified.) Failed PnP IRPs must be completed.
0x216	Non-fatal error	The previously-set IRP_MJ_PNP status has been converted to STATUS_NOT_SUPPORTED. (IRP specified.) This failure status is reserved for use by the operating system. Drivers cannot fail a PnP IRP with this value.
0x217	Non-fatal error	The driver has not handled a required IRP. The driver must update the status of the IRP to indicate whether or not it has been handled. (IRP specified.)
0x218	Non-fatal error	The driver has responded to an IRP that is reserved for other device objects elsewhere in the stack. (IRP specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x219	Non-fatal error	A non-successful non-STATUS_NOT_SUPPORTED IRP status for IRP_MJ_POWER is being passed down stack. (IRP specified.) Failed POWER IRPs must be completed.
0x21A	Non-fatal error	The previously-set IRP_MJ_POWER status has been converted to STATUS_NOT_SUPPORTED. (IRP specified.)
0x21B	Non-fatal error	A driver has returned a suspicious status. This is probably due to an uninitialized variable bug in the driver. (IRP specified.)
0x21C	Warning	The caller has copied the IRP stack but not set a completion routine. This is inefficient -- use IoSkipCurrentIrpStackLocation instead. (IRP specified.)
0x21D	Fatal error	An IRP dispatch handler has not properly detached from the stack below it upon receiving a remove IRP. (Device object, dispatch routine, and IRP specified.)
0x21E	Fatal error	An IRP dispatch handler has not properly deleted its device object upon receiving a remove IRP. (Device object, dispatch routine, and IRP specified.)
0x21F	Non-fatal error	A driver has not filled out a dispatch routine for a required IRP major function. (IRP specified.)
0x220	Non-fatal error	IRP_MJ_SYSTEM_CONTROL has been completed by someone other than the ProviderId. This IRP should either have been completed earlier or should have been passed down. (IRP specified, along with the device object where it was targeted.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x221	Fatal error	An IRP dispatch handler for a PDO has deleted its device object, but the hardware has not been reported as missing in a bus relations query. (Device object, dispatch routine, and IRP specified.)
0x222	Fatal error	A Bus Filter's IRP dispatch handler has detached upon receiving a remove IRP when the PDO is still alive. Bus Filters must clean up in FastIoDetach callbacks. (Device object, dispatch routine, and IRP specified.)
0x223	Fatal error	An IRP dispatch handler for a bus filter has deleted its device object, but the PDO is still present. Bus filters must clean up in FastIoDetach callbacks. (Device object, dispatch routine, and IRP specified.)
0x224	Fatal error	An IRP dispatch handler has returned a status that is inconsistent with the IRP's IoStatus.Status field. (Dispatch handler routine, IRP, IRP's IoStatus.Status , and returned Status specified.)
0x225	Non-fatal error	An IRP dispatch handler has returned a status that is illegal (0xFFFFFFFF). This is probably due to an uninitialized stack variable. To debug this error, use the In (List Nearest Symbols) command with the specified address.
0x226	Fatal error	An IRP dispatch handler has returned without passing down or completing this IRP, or someone forgot to return STATUS_PENDING. (IRP specified.)
0x227	Fatal error	An IRP completion routine is in pageable code. (This is never permitted.) (Routine and IRP specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x228	Non-fatal error	A driver's completion routine has not marked the IRP pending if the PendingReturned field was set in the IRP passed to it. This may cause Windows to hang, especially if an error is returned by the stack. (Routine and IRP specified.)
0x229	Fatal error	A cancel routine has been set for an IRP that is currently being processed by drivers lower in the stack, possibly stomping their cancel routine. (Routine and IRP specified.)
0x22A	Non-fatal error	The physical device object (PDO) has not responded to a required IRP. (IRP specified.)
0x22B	Non-fatal error	The physical device object (PDO) has forgotten to fill out the device relation list with the PDO for the TargetDeviceRelation query. (IRP specified.)
0x22C	Fatal error	The code implementing the TargetDeviceRelation query has not called ObReferenceObject on the PDO. (IRP specified.)
0x22D	Non-fatal error	The caller has completed a IRP_MJ_PNP it didn't understand instead of passing it down. (IRP specified.)
0x22E	Non-fatal error	The caller has completed a successful IRP_MJ_PNP instead of passing it down. (IRP specified.)
0x22F	Non-fatal error	The caller has completed an untouched IRP_MJ_PNP (instead of passing the IRP down), or non-PDO has failed the IRP using illegal value of STATUS_NOT_SUPPORTED. (IRP specified.)
0x230	Non-fatal error	The caller has completed an IRP_MJ_POWER it didn't understand instead of passing it down. (IRP specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x231	Fatal error	The caller has completed a successful IRP_MJ_POWER instead of passing it down. (IRP specified.)
0x232	Non-fatal error	The caller has completed an untouched IRP_MJ_POWER (instead of passing the IRP down), or non-PDO has failed the IRP using illegal value of STATUS_NOT_SUPPORTED. (IRP specified.)
0x233	Non-fatal error	The version field of the query capabilities structure in a query capabilities IRP was not properly initialized. (IRP specified.)
0x234	Non-fatal error	The size field of the query capabilities structure in a query capabilities IRP was not properly initialized. (IRP specified.)
0x235	Non-fatal error	The address field of the query capabilities structure in a query capabilities IRP was not properly initialized to -1. (IRP specified.)
0x236	Non-fatal error	The UI Number field of the query capabilities structure in a query capabilities IRP was not properly initialized to -1. (IRP specified.)
0x237	Fatal error	A driver has sent an IRP that is restricted for system use only. (IRP specified.)
0x238	Warning	The caller of IoInitializeIrp has passed an IRP that was allocated with IoAllocateIrp . This is illegal, unnecessary, and negatively impacts performance in normal use. If this IRP is being recycled, see IoReuseIrp in the Windows Driver Kit.
0x239	Warning	The caller of IoCompleteRequest is completing an IRP that has never been forwarded via a call to IoCallDriver or PoCallDriver . This may be a bug. (IRP specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x23A	Fatal error	A driver has forwarded an IRP at an IRQL that is illegal for this major code. (IRP specified.)
0x23B	Non-fatal error	The caller has changed the status field of an IRP it does not understand. (IRP specified.)

The following table lists additional **I/O Verification** errors that can appear in Windows XP and later. Some of these errors will only be revealed if **Enhanced I/O Verification** is activated. In Windows Vista and later, the **Enhanced I/O Verification** settings are included as part of **I/O Verification**.

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x23C	Fatal error	A driver has completed an IRP without setting the cancel routine in the IRP to NULL . (IRP specified.)
0x23D	Non-fatal error	A driver has returned STATUS_PENDING but did not mark the IRP pending via a call to IoMarkIrpPending . (IRP specified.)
0x23E	Non-fatal error	A driver has marked an IRP pending but didn't return STATUS_PENDING . (IRP specified.)
0x23F	Fatal error	A driver has not inherited the DO_POWER_PAGABLE bit from the stack it has attached to. (Device object specified.)
0x240	Fatal error	A driver is attempting to delete a device object that has already been deleted via a prior call to IoDeleteDevice .
0x241	Fatal error	A driver has detached its device object during a surprise remove IRP. (IRP and device object specified.)
0x242	Fatal error	A driver has deleted its device object during a surprise remove IRP. (IRP and device object specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x243	Fatal error	A driver has failed to clear the DO_DEVICE_INITIALIZING flag at the end of AddDevice . (Device object specified.)
0x244	Fatal error	A driver has not copied either the DO_BUFFERED_IO or the DO_DIRECT_IO flag from the device object it is attaching to. (Device object specified.)
0x245	Fatal error	A driver has set both the DO_BUFFERED_IO and the DO_DIRECT_IO flags. These flags are mutually exclusive. (Device object specified.)
0x246	Fatal error	A driver has failed to copy the DeviceType field from the device object it is attaching to. (Device object specified.)
0x247	Fatal error	A driver has failed an IRP that cannot legally be failed. (IRP specified.)
0x248	Fatal error	A driver has added a device object that is not a PDO to a device relations query. (IRP and device object specified.)
0x249	Non-fatal error	A driver has enumerated two child PDOs that returned identical Device IDs. (Both device objects specified.)
0x24A	Fatal error	A driver has mistakenly called a file I/O function with IRQL not equal to PASSIVE_LEVEL.
0x24B	Fatal error	A driver has completed an IRP_MN_QUERY_DEVICE_RELATION S request of type TargetDeviceRelation as successful, but did not properly fill out the request or forward the IRP to the underlying hardware stack. (Device object specified.)

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x24C	Non-fatal error	A driver has returned STATUS_PENDING but did not mark the IRP pending by a call to IoMarkIrpPending . (IRP specified.)
0x24D	Fatal error	A driver has passed an invalid device object to a function that requires a PDO. (Device object specified.)
0x300	Non-fatal error	A driver has returned a suspicious status. This is probably due to an uninitialized variable bug in the driver.
0x301	Non-fatal error	A driver has forwarded an IRP at IRQL > DISPATCH_LEVEL. (IRQL value specified)
0x302	Non-fatal error	A driver has forwarded an IRP at IRQL >= APC_LEVEL. The I/O Manager will need to queue an APC to complete this request. The APC will not be able to run because the caller is already at APC level, so the caller is likely to deadlock. (IRQL value specified)
0x306	Non-fatal error	The driver is completing an IRP_MJ_PNP (major) and IRP_MN_REMOVE_DEVICE (minor) request with a failure status code.
0x307	Non-fatal error	The driver issued an I/O request with an event that was already signaled and received a STATUS_PENDING response. This can result in unwinding before the I/O is complete.
0x310	Non-fatal error	The driver is reinitializing an IRP that is still in use.
0x311	Non-fatal error	The driver is reinitializing an IRP that was created with IoMakeAssociatedIrp , IoBuildAsynchronousFsdRequest , IoBuildSynchronousFsdRequest , IoBuildDeviceIoControlRequest .

I/O ERROR CODE	SEVERITY	CAUSE OF ERROR
0x312	Non-fatal error	The caller provided the IRP Status Information field with a value that is greater than the output section of the system buffer.

Cause

See the description of each code in the Parameters section for a description of the cause.

Resolution

This bug check can only occur when Driver Verifier has been instructed to monitor one or more drivers. If you did not intend to use Driver Verifier, you should deactivate it. You might consider removing the driver which caused this problem as well.

If you are the driver writer, use the information obtained through this bug check to fix the bugs in your code.

For full details on Driver Verifier, see the Windows Driver Kit.

Bug Check 0xCA: PNP_DETECTED_FATAL_ERROR

5/26/2017 • 2 min to read • [Edit Online](#)

The PNP_DETECTED_FATAL_ERROR bug check has a value of 0x000000CA. This indicates that the Plug and Play Manager encountered a severe error, probably as a result of a problematic Plug and Play driver.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PNP_DETECTED_FATAL_ERROR Parameters

Parameter 1 identifies the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1	Address of newly-reported PDO	Address of older PDO which has been duplicated	Reserved	Duplicate PDO: A specific instance of a driver has enumerated multiple PDOs with identical device ID and unique IDs.
0x2	Address of purported PDO	Address of driver object	Reserved	Invalid PDO: An API which requires a PDO has been called with random memory, or with an FDO, or with a PDO which hasn't been initialized. (An uninitialized PDO is one that has not been returned to Plug and Play by QueryDeviceRelation or QueryBusRelations .)

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x3	Address of PDO whose IDs were queried	Address of ID buffer	1: DeviceID 2: UniqueID 3: HardwareIDs 4: CompatibleIDs	Invalid ID: An enumerator has returned an ID which contains illegal characters or isn't properly terminated. (IDs must contain only characters in the ranges 0x20 - 0x2B and 0x2D - 0x7F.)
0x4	Address of PDO with DOE_DELETE_PEN DING set	Reserved	Reserved	Invalid enumeration of deleted PDO: An enumerator has returned a PDO which it had previously deleted using IoDeleteDevice .
0x5	Address of PDO	Reserved	Reserved	PDO freed while linked in devnode tree: The object manager reference count on a PDO dropped to zero while the devnode was still linked in the tree. (This usually indicates that the driver is not adding a reference when returning the PDO in a query IRP.)
0x8	Address of PDO whose stack returned the invalid bus relation	Total number of PDOs returned as bus relations	The index (zero-based) at which the first NULL PDO was found	NULL pointer returned as a bus relation: One or more of the devices present on the bus is a NULL PDO.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x9	Connection type that was passed	Reserved	Reserved	<p>Invalid connection type passed to <code>IoDisconnectInterruptEx</code>: A driver has passed an invalid connection type to <code>IoDisconnectInterruptEx</code>. The connection type passed to this routine must match the one returned by a corresponding successful call to <code>IoConnectInterruptEx</code>.</p>
0xA	Driver object	IRQL after returning from driver callback	Combined APC disable count after returning from driver callback	<p>Incorrect notify callback behavior: A driver failed to preserve IRQL or combined APC disable count across a Plug 'n' Play notification.</p>
0xB	Related PDO	Removal relations	Reserved	<p>Deleted PDO reported as relation: One of the removal relations for the device being removed has already been deleted.</p>

Bug Check 0xCB: DRIVER_LEFT_LOCKED_PAGES_IN_PROCESS

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_LEFT_LOCKED_PAGES_IN_PROCESS bug check has a value of 0x000000CB. This indicates that a driver or the I/O manager failed to release locked pages after an I/O operation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_LEFT_LOCKED_PAGES_IN_PROCESS Parameters

The four parameters listed in the message can have two possible meanings.

If a driver locked these pages, the parameters have the following meaning.

PARAMETER	DESCRIPTION
1	Calling address in the driver that locked the pages
2	Caller of the calling address in driver that locked the pages
3	Address of the MDL containing the locked pages
4	Number of locked pages

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

If the I/O manager locked these pages, the parameters have the following meaning.

PARAMETER	DESCRIPTION
1	Address of the dispatch routine of the top driver on the stack to which the IRP was sent
2	Address of the device object of the top driver on the stack to which the IRP was sent
3	Address of the MDL containing the locked pages
4	Number of locked pages

Remarks

This bug check is issued only if the registry value

\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory

Management\TrackLockedPages is equal to DWORD 1. If this value is not set, the system will issue the less-informative [bug check 0x76](#) (PROCESS_HAS_LOCKED_PAGES).

Starting with Windows Vista, this bug check can also be issued by Driver Verifier when the Pool Tracking option is enabled.

Bug Check 0xCC: PAGE_FAULT_IN_FREED_SPECIAL_POOL

5/26/2017 • 1 min to read • [Edit Online](#)

The PAGE_FAULT_IN_FREED_SPECIAL_POOL bug check has a value of 0x000000CC. This indicates that the system has referenced memory which was earlier freed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PAGE_FAULT_IN_FREED_SPECIAL_POOL Parameters

PARAMETER	DESCRIPTION
1	Memory address referenced
2	0: Read 1: Write
3	Address that referenced memory (if known)
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

The Driver Verifier Special Pool option has caught the system accessing memory which was earlier freed. This usually indicates a system-driver synchronization problem.

For information about the special pool, consult the Driver Verifier section of the Windows Driver Kit.

Remarks

This cannot be protected by a **try - except** handler -- it can only be protected by a probe.

Bug Check 0xCD: PAGE_FAULT_BEYOND_END_OF_ALLOCATION

5/26/2017 • 1 min to read • [Edit Online](#)

The PAGE_FAULT_BEYOND_END_OF_ALLOCATION bug check has a value of 0x000000CD. This indicates that the system accessed memory beyond the end of some driver's pool allocation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PAGE_FAULT_BEYOND_END_OF_ALLOCATION Parameters

PARAMETER	DESCRIPTION
1	Memory address referenced
2	0: Read 1: Write
3	Address that referenced memory (if known)
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

The driver allocated n bytes of memory from the special pool. Subsequently, the system referenced more than n bytes from this pool. This usually indicates a system-driver synchronization problem.

For information about the special pool, consult the Driver Verifier section of the Windows Driver Kit.

Remarks

This cannot be protected by a **try - except** handler -- it can only be protected by a probe.

Bug Check 0xCE: DRIVER_UNLOADED_WITHOUT_CANCELLED_PENDING_OPERATIONS

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_UNLOADED_WITHOUT_CANCELLED_PENDING_OPERATIONS bug check has a value of 0x000000CE. This indicates that a driver failed to cancel pending operations before unloading.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_UNLOADED_WITHOUT_CANCELLED_PENDING_OPERATIONS Parameters

PARAMETER	DESCRIPTION
1	Memory address referenced
2	0: Read 1: Write
3	Address that referenced memory (if known)
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

This driver failed to cancel lookaside lists, DPCs, worker threads, or other such items before unload.

Bug Check 0xCF: TERMINAL_SERVER_DRIVER_MADE_INCORRECT_MEMORY_REFERENCE

5/26/2017 • 1 min to read • [Edit Online](#)

The TERMINAL_SERVER_DRIVER_MADE_INCORRECT_MEMORY_REFERENCE bug check has a value of 0x000000CF. This indicates that a driver has been incorrectly ported to the terminal server.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

TERMINAL_SERVER_DRIVER_MADE_INCORRECT_MEMORY_REFERENCE Parameters

PARAMETER	DESCRIPTION
1	Memory address referenced
2	0: Read 1: Write
3	Address that referenced memory (if known)
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

The driver is referencing session space addresses from the system process context. This probably results from the driver queuing an item to a system worker thread.

This driver needs to comply with Terminal Server's memory management rules.

Bug Check 0xD0: DRIVER_CORRUPTED_MMPOOL

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_CORRUPTED_MMPOOL bug check has a value of 0x000000D0. This indicates that the system attempted to access invalid memory at a process IRQL that was too high.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_CORRUPTED_MMPOOL Parameters

PARAMETER	DESCRIPTION
1	Memory referenced
2	IRQL at time of reference
3	0: Read 1: Write
4	Address that referenced memory

Cause

The kernel attempted to access pageable memory (or perhaps completely invalid memory) when the IRQL was too high. The ultimate cause of this problem is almost certainly a driver that has corrupted the system pool.

In most cases, this bug check results if a driver corrupts a large allocation (PAGE_SIZE or larger). Smaller allocations result in [bug check 0xC5](#) (DRIVER_CORRUPTED_EXPOOL).

Resolution

If you have recently installed any new software, check to see if it is properly installed. Check for updated drivers on the manufacturer's website.

To debug this error, use the special pool option of Driver Verifier. If this fails to reveal the driver that caused the error, use the Global Flags utility to enable the special pool by pool tag.

For information about the special pool, consult the Driver Verifier section of the Windows Driver Kit.

An alternate method is to open the **\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management** registry key. In this key, create or edit the **ProtectNonPagedPool** value, and set it equal to DWORD 1. Then reboot. Then the system will unmap all freed nonpaged pool. This will prevent drivers from corrupting the pool. (This does not protect the pool from DMA hardware, however.)

Bug Check 0xD1: DRIVER_IRQL_NOT_LESS_OR_EQUAL

5/26/2017 • 2 min to read • [Edit Online](#)

The DRIVER_IRQL_NOT_LESS_OR_EQUAL bug check has a value of 0x000000D1. This indicates that a kernel-mode driver attempted to access pageable memory at a process IRQL that was too high.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_IRQL_NOT_LESS_OR_EQUAL Parameters

PARAMETER	DESCRIPTION
1	Memory referenced
2	IRQL at time of reference
3	0: Read 1: Write 8: Execute
4	Address that referenced memory

Cause

A driver tried to access an address that is pageable (or that is completely invalid) while the IRQL was too high.

This bug check is usually caused by drivers that have used improper addresses.

If the first parameter has the same value as the fourth parameter, and the third parameter indicates an execute operation, this bug check was likely caused by a driver that was trying to execute code when the code itself was paged out. Possible causes for the page fault include the following:

- The function was marked as pageable and was running at an elevated IRQL (which includes obtaining a lock).
- The function call was made to a function in another driver, and that driver was unloaded.
- The function was called by using a function pointer that was an invalid pointer.

Resolution

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in determining the root cause.

For more information, see [Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

To start, examine the stack trace using the **k, kb, kc, kd, kp, kP, kv (Display Stack Backtrace)** command.

If the problem is caused by the driver that you are developing, make sure that the function that was executing at the time of the bug check is not marked as pageable or does not call any other inline functions that could be paged out.

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- For additional general troubleshooting information, see [Blue Screen Data](#).

Bug Check 0xD2: BUGCODE_ID_DRIVER

5/26/2017 • 2 min to read • [Edit Online](#)

The BUGCODE_ID_DRIVER bug check has a value of 0x000000D2. This indicates that a problem occurred with an NDIS driver.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BUGCODE_ID_DRIVER Parameters

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	MESSAGE AND CAUSE
Address of the miniport block	Number of bytes requested	0	1	Allocating shared memory at raised IRQL. A driver called NdisMAllocateSharedMemory with IRQL >= DISPATCH_LEVEL.
Address of the miniport block	The <i>Status</i> value submitted to NdisMResetComplete	The <i>AddressingReset</i> value submitted to NdisMResetComplete	0	Completing reset when one is not pending. A driver called NdisMResetComplete , but no reset was pending.
Address of the miniport block	Memory page containing address being freed	Address of shared memory signature	Virtual address being freed	Freeing shared memory not allocated. A driver called NdisMFreeSharedMemory or NdisMFreeSharedMemoryAsync with an address that is not located in NDIS shared memory.
Address of the miniport block	Address of the packet that is incorrectly included in the packet array	Address of the packet array	Number of packets in the array	Indicating packet not owned by it. The miniport's packet array is corrupt.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	MESSAGE AND CAUSE
Address of the MiniBlock	Address of the driver object	0	0	NdisAddDevice: AddDevice called with a MiniBlock that is not on the NdisMiniDriverList .
Address of the MiniBlock	The MiniBlock's reference count	0	0	NdisMUnload: MiniBlock is getting unloaded but it is still on NdisMiniDriverList .
Address of the miniport block	Memory page	Wrapper context	Address of shared memory signature	Overwrote past allocated shared memory. The address being written to is not located in NDIS shared memory.

In the following instances of this bug check, the meaning of the parameters depends on the message and on the value of Parameter 4.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	MESSAGE AND CAUSE
Address of the miniport block	Address of the miniport interrupt	Address of the miniport timer queue	1	Unloading without deregistering interrupt. A miniport driver failed its initialization without deregistering its interrupt.
Address of the miniport block	Address of the miniport timer queue	Address of the miniport interrupt	2	Unloading without deregistering interrupt. A miniport driver did not deregister its interrupt during the halt process.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	MESSAGE AND CAUSE
Address of the miniport block	Address of the miniport interrupt	Address of the miniport timer queue	1	Unloading without deregistering timer. A miniport driver failed its initialization without successfully canceling all its timers.
Address of the miniport block	Address of the miniport timer queue	Address of the miniport interrupt	2	Unloading without deregistering timer. A miniport driver halted without successfully canceling all its timers.

Remarks

This bug check code only occurs on Windows 2000 and Windows XP. In Windows Server 2003 and later, the corresponding code is **bug check 0x7C** (BUGCODE_NDIS_DRIVER).

On the checked build of Windows, only the **Allocating Shared Memory at Raised IRQL** and **Completing Reset When One is Not Pending** instances of this bug check can occur. All the other instances of bug check 0xD2 are replaced with ASSERTs. See [Breaking Into the Debugger](#) for details.

Bug Check 0xD3: DRIVER_PORTION_MUST_BE_NONPAGED

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_PORTION_MUST_BE_NONPAGED bug check has a value of 0x000000D3. This indicates that the system attempted to access pageable memory at a process IRQL that was too high.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_PORTION_MUST_BE_NONPAGED Parameters

PARAMETER	DESCRIPTION
1	Memory referenced
2	IRQL at time of reference
3	0: Read 1: Write
4	Address that referenced memory

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

This bug check is usually caused by drivers that have incorrectly marked their own code or data as pageable.

Resolution

To begin debugging, use a kernel debugger to get a stack trace.

Bug Check 0xD4: SYSTEM_SCAN_AT_RAISED_IRQL_CAUGHT_IMPROPER_DRIVER_UNLOAD

5/26/2017 • 1 min to read • [Edit Online](#)

The SYSTEM_SCAN_AT_RAISED_IRQL_CAUGHT_IMPROPER_DRIVER_UNLOAD bug check has a value of 0x000000D4. This indicates that a driver did not cancel pending operations before unloading.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SYSTEM_SCAN_AT_RAISED_IRQL_CAUGHT_IMPROPER_DRIVER_UNLOAD Parameters

PARAMETER	DESCRIPTION
1	Memory referenced
2	IRQL at time of reference
3	0: Read 1: Write
4	Address that referenced memory

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

This driver failed to cancel lookaside lists, DPCs, worker threads, or other such items before unload. Subsequently, the system attempted to access the driver's former location at a raised IRQL.

Resolution

To begin debugging, use a kernel debugger to get a stack trace. If the driver that caused the error has been identified, activate Driver Verifier and attempt to replicate this bug.

For full details on Driver Verifier, see the Windows Driver Kit.

Bug Check 0xD5: DRIVER_PAGE_FAULT_IN_FREED_SPECIAL_POOL

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_PAGE_FAULT_IN_FREED_SPECIAL_POOL bug check has a value of 0x000000D5. This indicates that a driver has referenced memory which was earlier freed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_PAGE_FAULT_IN_FREED_SPECIAL_POOL Parameters

PARAMETER	DESCRIPTION
1	Memory address referenced
2	0: Read 1: Write
3	Address that referenced memory (if known)
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

The Driver Verifier **Special Pool** option has caught the driver accessing memory which was earlier freed.

For information about the special pool, consult the Driver Verifier section of the Windows Driver Kit.

Remarks

This cannot be protected by a **try - except** handler -- it can only be protected by a probe.

Bug Check 0xD6: DRIVER_PAGE_FAULT_BEYOND_END_OF_ALLOCATION

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_PAGE_FAULT_BEYOND_END_OF_ALLOCATION bug check has a value of 0x000000D6. This indicates the driver accessed memory beyond the end of its pool allocation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_PAGE_FAULT_BEYOND_END_OF_ALLOCATION Parameters

PARAMETER	DESCRIPTION
1	Memory address referenced
2	0: Read 1: Write
3	Address that referenced memory (if known)
4	Reserved

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) *KiBugCheckDriver*.

Cause

The driver allocated n bytes of memory and then referenced more than n bytes. The Driver Verifier **Special Pool** option detected this violation.

For information about the special pool, consult the Driver Verifier section of the Windows Driver Kit.

Remarks

This cannot be protected by a **try - except** handler -- it can only be protected by a probe.

Bug Check 0xD7: DRIVER_UNMAPPING_INVALID_VIEW

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_UNMAPPING_INVALID_VIEW bug check has a value of 0x000000D7. This indicates a driver is trying to unmap an address that was not mapped.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_UNMAPPING_INVALID_VIEW Parameters

PARAMETER	DESCRIPTION
1	Virtual address to unmap
2	1: The view is being unmapped 2: The view is being committed
3	0
4	0

Remarks

The driver that caused the error can be determined from the stack trace.

Bug Check 0xD8: DRIVER_USED_EXCESSIVE_PTES

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_USED_EXCESSIVE_PTES bug check has a value of 0x000000D8. This indicates that there are no more system page table entries (PTE) remaining.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_USED_EXCESSIVE_PTES Parameters

PARAMETER	DESCRIPTION
1	Pointer to the name of the driver that caused the error (Unicode string), or zero
2	Number of PTEs used by the driver that caused the error (if Parameter 1 is nonzero)
3	Total free system PTEs
4	Total system PTEs

If the driver responsible for the error can be identified, its name is printed on the blue screen and stored in memory at the location (PUNICODE_STRING) **KiBugCheckDriver**.

Cause

This is usually caused by a driver not cleaning up its memory use properly. Parameter 1 shows the driver which has consumed the most PTEs. The call stack will reveal which driver actually caused the bug check.

Resolution

Both drivers may need to be fixed. The total number of system PTEs may also need to be increased.

Bug Check 0xD9: LOCKED_PAGES_TRACKER_CORRUPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The LOCKED_PAGES_TRACKER_CORRUPTION bug check has a value of 0x000000D9. This indicates that the internal locked-page tracking structures have been corrupted.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

LOCKED_PAGES_TRACKER_CORRUPTION Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x01	The address of the internal lock tracking structure	The address of the memory descriptor list	The number of pages locked for the current process	The MDL is being inserted twice on the same process list.
0x02	The address of the internal lock tracking structure	The address of the memory descriptor list	The number of pages locked for the current process	The MDL is being inserted twice on the systemwide list.
0x03	The address of the first internal tracking structure found	The address of the internal lock tracking structure	The address of the memory descriptor list	The MDL was found twice in the process list when being freed.
0x04	The address of the internal lock tracking structure	The address of the memory descriptor list	0	The MDL was found in the systemwide list on free after it was removed.

Cause

The error is indicated by the value of Parameter 1.

Bug Check 0xDA: SYSTEM_PTE_MISUSE

5/26/2017 • 7 min to read • [Edit Online](#)

The SYSTEM_PTE_MISUSE bug check has a value of 0x000000DA. This indicates that a page table entry (PTE) routine has been used in an improper way.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SYSTEM_PTE_MISUSE Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x01	The address of the internal lock tracking structure	The address of the memory descriptor list	The address of the duplicate internal lock tracking structure	The mapping being freed is a duplicate.
0x02	The address of the internal lock tracking structure	The number of mappings that the system expects to free	The number of mappings that the driver is requesting to free	The number of mappings being freed is incorrect.
0x03	The address of the first internal tracking structure found	The mapping address that the system expects to free	The mapping address that the driver is requesting to free	The mapping address being freed is incorrect.
0x04	The address of the internal lock tracking structure	The page frame number that the system expects should be first in the MDL	The page frame number that is currently first in the MDL	The first page of the mapped MDL has changed since the MDL was mapped.
0x05	The address of the first internal tracking structure found	The virtual address that the system expects to free	The virtual address that the driver is requesting to free	The start virtual address in the MDL being freed has changed since the MDL was mapped.
0x06	The MDL specified by the driver	The virtual address specified by the driver	The number of mappings to free (specified by the driver)	The MDL being freed was never (or is currently not) mapped.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x07	The initial mapping	The number of mappings	Reserved	(Windows 2000 only) The mapping range is being double-allocated.
0x08	The initial mapping	The number of mappings the caller is freeing	The number of mappings the system thinks should be freed	(Windows 2000 only) The caller is asking to free an incorrect number of mappings.
0x09	The initial mapping	The number of mappings that the caller is freeing	The mapping index that the system thinks is already free	(Windows 2000 only) The caller is asking to free several mappings, but at least one of them is not allocated.
0x0A	1: The driver requested "bug check on failure" in the MDL. 0: The driver did not request "bug check on failure" in the MDL.	The number of mappings that the caller is allocating	The type of mapping pool requested	(Windows 2000 only) The caller is asking to allocate zero mappings.
0x0B	The corrupt mapping	The number of mappings that the caller is allocating	The type of mapping pool requested	(Windows 2000 only) The mapping list was already corrupt at the time of this allocation. The corrupt mapping is located below the lowest possible mapping address.
0x0C	The corrupt mapping	The number of mappings that the caller is allocating	The type of mapping pool requested	(Windows 2000 only) The mapping list was already corrupt at the time of this allocation. The corrupt mapping is located above the lowest possible mapping address.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0D	The initial mapping	The number of mappings that the caller is freeing	The type of mapping pool	(Windows 2000 only) The caller is trying to free zero mappings.
0x0E	The initial mapping	The number of mappings that the caller is freeing	The type of mapping pool	(Windows 2000 only) The caller is trying to free mappings, but the guard mapping has been overwritten.
0x0F	The non-existent mapping	The number of mappings that the caller is trying to free	The type of mapping pool being freed	(Windows 2000 only) The caller is trying to free a non-existent mapping. The non-existent mapping is located below the lowest possible mapping address.
0x10	The non-existent mapping	The number of mappings the caller is trying to free	The type of mapping pool being freed	(Windows 2000 only) The caller is trying to free a non-existent mapping. The non-existent mapping is located above the highest possible mapping address.
0x11	The non-existent mapping	The number of mappings that the caller is trying to free	The type of mapping pool being freed	(Windows 2000 only) The caller is trying to free a non-existent mapping. The non-existent mapping is at the base of the mapping address space.
0x100	The number of mappings being requested	The caller's identifying tag	The address of the routine that called the caller of this routine	(Windows XP and later only) The caller requested 0 mappings.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x101	The first mapping address	The caller's identifying tag	The owner's identifying tag	(Windows XP and later only) A caller is trying to free a mapping address range that it does not own.
0x102	The first mapping address	The caller's identifying tag	Reserved	(Windows XP and later only) The mapping address space that the caller is trying to free is apparently empty.
0x103	The address of the invalid mapping	The caller's identifying tag	The number of mappings in the mapping address space	(Windows XP and later only) The mapping address space that the caller is trying to free is still reserved. MmUnmapReservedMapping must be called before MmFreeMappingAddress .
0x104	The first mapping address	The caller's identifying tag	The owner's identifying tag	(Windows XP and later only) The caller is attempting to map an MDL to a mapping address space that it does not own.
0x105	The first mapping address	The caller's identifying tag	Reserved	(Windows XP and later only) The caller is attempting to map an MDL to an invalid mapping address space. The caller has mostly likely specified an invalid address.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x107	The first mapping address	The address of the non-empty mapping	The last mapping address	(Windows XP and later only) The caller is attempting to map an MDL to a mapping address space that has not been properly reserved. The caller should have called MmUnmapReservedMapping prior to calling MmMapLockedPagesWithReservedMapping
0x108	The first mapping address	The caller's identifying tag	The owner's identifying tag	(Windows XP and later only) The caller is attempting to unmap a locked mapping address space that it does not own.
0x109	The first mapping address	The caller's identifying tag	Reserved	(Windows XP and later only) The caller is attempting to unmap a locked virtual address space that is apparently empty.
0x10A	The first mapping address	The number of mappings in the locked mapping address space	The number of mappings to unmap	(Windows XP and later only) The caller is attempting to unmap more mappings than actually exist in the locked mapping address space.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x10B	The first mapping address	The caller's identifying tag	The number of mappings to unmap	(Windows XP and later only) The caller is attempting to unmap a portion of a locked virtual address space that is not currently mapped.
0x10C	The first mapping address	The caller's identifying tag	The number of mappings to unmap	(Windows XP and later only) The caller is not unmapping the entirety of the locked mapping address space.
0x200	The first mapping address	0	0	(Windows XP and later only) The caller is attempting to reserve a mapping address space that contains no mappings.
0x201 0x202	The first mapping address to reserve	The address of the mapping that has already been reserved	The number of mappings to reserve	(Windows XP and later only) One of the mappings that the caller is attempting to reserve has already been reserved.
0x300	The first mapping address to release	0	0	(Windows XP and later only) The caller is attempting to release a mapping address space that contains no mappings.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x301	The address of the mapping	0	0	(Windows XP and later only) The caller is attempting to release a mapping that it is not permitted to release.
0x302	The address that the caller is trying to release.	Reserved	Reserved	The caller is attempting to release a system address that is not currently mapped.
0x303	The first mapping address	The number of mappings to release	0	(Windows XP and later only) The caller is attempting to release a mapping address range that was not reserved.
0x304	The first mapping address	The number of mappings to release	0	(Windows XP and later only) The caller is attempting to release a mapping address range that begins in the middle of a different allocation.
0x305	The first mapping address	The number of mappings that the caller is trying to release	The number of mappings that should be released	(Windows XP and later only) The caller is attempting to release the wrong number of mappings.
0x306	The first mapping address	The free mapping address	The number of mappings to release	(Windows XP and later only) One of the mappings that the caller is attempting to release is already free.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x400	The base address of the I/O space mapping	The number of pages to be freed	0	(Windows XP and later only) The caller is trying to free an I/O space mapping that the system is unaware of.

Cause

The error is indicated by the value of Parameter 1.

A stack trace will identify the driver that caused the error.

Bug Check 0xDB: DRIVER_CORRUPTED_SYSPTES

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_CORRUPTED_SYSPTES bug check has a value of 0x000000DB. This indicates that an attempt was made to touch memory at an invalid IRQL, probably due to corruption of system PTEs.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_CORRUPTED_SYSPTES Parameters

PARAMETER	DESCRIPTION
1	Memory referenced
2	IRQL
3	0: Read 1: Write
4	Address in code which referenced memory

Cause

A driver tried to access pageable (or completely invalid) memory at too high of an IRQL. This bug check is almost always caused by drivers that have corrupted system PTEs.

Resolution

If this bug check occurs, the culprit can be detected by editing the registry. In the **\\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Memory Management** registry key, create or edit the **TrackPtes** value, and set it equal to DWORD 3. Then reboot. The system will then save stack traces, and if the driver commits the same error, the system will issue **bug check 0xDA** (SYSTEM_PTE_MISUSE). Then the stack trace will identify the driver that caused the error.

Bug Check 0xDC: DRIVER_INVALID_STACK_ACCESS

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_INVALID_STACK_ACCESS bug check has a value of 0x000000DC. This indicates that a driver accessed a stack address that lies below the stack pointer of the stack's thread.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_INVALID_STACK_ACCESS Parameters

None

Bug Check 0xDE: POOL_CORRUPTION_IN_FILE_AREA

5/26/2017 • 1 min to read • [Edit Online](#)

The POOL_CORRUPTION_IN_FILE_AREA bug check has a value of 0x000000DE. This indicates that a driver has corrupted pool memory that is used for holding pages destined for disk.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

POOL_CORRUPTION_IN_FILE_AREA Parameters

None

Cause

When the Memory Manager dereferenced the file, it discovered this corruption in pool memory.

Bug Check 0xDF: IMPERSONATING_WORKER_THREAD

5/26/2017 • 1 min to read • [Edit Online](#)

The IMPERSONATING_WORKER_THREAD bug check has a value of 0x000000DF. This indicates that a workitem did not disable impersonation before it completed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

IMPERSONATING_WORKER_THREAD Parameters

PARAMETER	DESCRIPTION
1	The worker routine that caused this error
2	The parameter passed to this worker routine
3	A pointer to the work item
4	Reserved

Cause

A worker thread was impersonating another process, and failed to disable impersonation before it returned.

Bug Check 0xE0: ACPI_BIOS_FATAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The ACPI_BIOS_FATAL_ERROR bug check has a value of 0x000000E0. This indicates that one of your computer components is faulty.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ACPI_BIOS_FATAL_ERROR Parameters

The parameters for this bug check are issued by the BIOS, not by Windows. They can only be interpreted by the hardware vendor.

Cause

Your computer's BIOS has reported that a component in the system is so faulty that there is no way for Windows to operate. The BIOS is indicating that there is no alternative but to issue a bug check.

Resolution

You can determine which component is faulty by running the diagnostic disk or tool that was included with your computer.

If you do not have this tool, you must contact the system vendor and report this error message to them. They will be able to help you correct this hardware problem. This enables Windows to operate.

Microsoft cannot address this error. Only the hardware vendor is qualified to analyze it.

Bug Check 0xE1: WORKER_THREAD_RETURNED_AT_BAD_IRQL

5/26/2017 • 1 min to read • [Edit Online](#)

The WORKER_THREAD_RETURNED_AT_BAD_IRQL bug check has a value of 0x000000E1. This indicates that a worker thread completed and returned with IRQL >= DISPATCH_LEVEL.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WORKER_THREAD_RETURNED_AT_BAD_IRQL Parameters

PARAMETER	DESCRIPTION
1	Address of the worker routine
2	IRQL that the worker thread returned at
3	Work item parameter
4	Work item address

Cause

A worker thread completed and returned with IRQL >= DISPATCH_LEVEL.

Resolution

To find the driver that caused the error, use the [In \(List Nearest Symbols\)](#) debugger command:

```
kd> ln address
```

where *address* is the worker routine address given in Parameter 1.

Bug Check 0xE2: MANUALLY_INITIATED_CRASH

5/26/2017 • 1 min to read • [Edit Online](#)

The MANUALLY_INITIATED_CRASH bug check has a value of 0x000000E2. This indicates that the user deliberately initiated a crash dump from either the kernel debugger or the keyboard.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MANUALLY_INITIATED_CRASH Parameters

None

Remarks

For more information about manually-initiated crash dumps, see [Forcing a System Crash](#).

Bug Check 0xE3: RESOURCE_NOT OWNED

5/26/2017 • 1 min to read • [Edit Online](#)

The RESOURCE_NOT OWNED bug check has a value of 0x000000E3. This indicates that a thread tried to release a resource it did not own.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

RESOURCE_NOT OWNED Parameters

PARAMETER	DESCRIPTION
1	Address of resource
2	Address of thread
3	Address of owner table (if it exists)
4	Reserved

Bug Check 0xE4: WORKER_INVALID

5/26/2017 • 1 min to read • [Edit Online](#)

The WORKER_INVALID bug check has a value of 0x000000E4. This indicates that memory that should not contain an executive work item does contain such an item, or that a currently active work item was queued.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WORKER_INVALID Parameters

Parameter 1 indicates the code position.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0	Address of work item	Start of pool block	End of pool block	An active worker item was freed.
0x1	Address of work item	Queue number	0	An active worker item was queued.
0x2	Address of work item	Address of I/O worker routine	0	A queued I/O worker item was freed.
0x3	Address of work item	Address of invalid object	0	An attempt was made to initialize an I/O worker item with an invalid object.
0x5	Address of work item	Queue number	NUMA Node targeted or -1 if all NODES were searched for.	An attempt was made to queue a work item before Worker Queued was initialized.
0x6	Address of work item	Queue number	0	Invalid queue type was provided.
0x7	Address of work item	Queue number	0	An attempt was made to queue a work item with an invalid worker routine address.

Cause

This is usually caused by a driver freeing memory which still contains an executive work item.

Bug Check 0xE6: DRIVER_VERIFIER_DMA_VIOLATION

5/26/2017 • 4 min to read • [Edit Online](#)

The DRIVER_VERIFIER_DMA_VIOLATION bug check has a value of 0x000000E6. This is the bug check code for all Driver Verifier **DMA Verification** violations.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_VERIFIER_DMA_VIOLATION Parameters

Parameter 1 is the only parameter of interest. This parameter identifies the exact violation. If a debugger is attached, an informative message is displayed in the debugger.

PARAMETER 1	CAUSE OF ERROR AND DEBUGGER MESSAGE
0x00	<p>This code can represent two kinds of errors:</p> <ol style="list-style-type: none">1. The driver tried to flush too many bytes to the end of the map register file. The number of bytes permitted and the number of bytes attempted are displayed.2. Windows has run out of contiguous map registers. The number of map registers needed and the largest block of contiguous map registers is displayed.
0x01	<p>The performance counter has decreased. The old and new values of the counter are displayed.</p>
0x02	<p>The performance counter has increased too fast. The counter value is displayed in the debugger.</p>
0x03	<p>The driver freed too many DMA common buffers. Usually this means it freed the same buffer two times.</p>
0x04	<p>The driver freed too many DMA adapter channels. Usually this means it freed the same adapter channel two times.</p>
0x05	<p>The driver freed too many DMA map registers. Usually this means it freed the same map register two times. The number of active map registers is displayed.</p>
0x06	<p>The driver freed too many DMA scatter/gather lists. Usually this means it freed the same scatter/gather list two times. The number of lists allocated and the number of lists freed is displayed.</p>

PARAMETER 1	CAUSE OF ERROR AND DEBUGGER MESSAGE
0x07	The driver tried to release the adapter without first freeing all its common buffers. The adapter address and the number of remaining buffers is displayed.
0x08	The driver tried to release the adapter without first freeing all adapter channels, common buffers, or scatter/gather lists. The adapter address and the number of remaining items is displayed.
0x09	The driver tried to release the adapter without first freeing all map registers. The adapter address and the number of remaining map registers is displayed.
0x0A	The driver tried to release the adapter without first freeing all its scatter/gather lists. The adapter address and the number of remaining scatter/gather lists is displayed.
0x0B	HV_TOO_MANY_ADAPTER_CHANNELS The driver has allocated too many adapter channels at the same time. . (Only one adapter channel is permitted per adapter.)
0x0C	The driver tried to allocate too many map registers at the same time. The number requested and the number allowed are displayed.
0x0D	The driver did not flush its adapter buffers. The number of bytes that the driver tried to map and the maximum number of bytes allowed are displayed.
0x0E	The driver tried a DMA transfer without locking the buffer. The buffer in question was in paged memory. The address of the MDL is displayed.
0x0F	The driver or the hardware wrote outside its allocated DMA buffer. The nature of the error (overrun or underrun) is displayed, as well as the relevant addresses.
0x10	The driver tried to free its map registers while some were still mapped. The number of map registers still mapped is displayed.
0x11	The driver has too many outstanding reference counts for the adapter. The number of reference counts and the adapter address are displayed.
0x13	The driver called a DMA routine at an improper IRQL. The required IRQL and the actual IRQL are displayed.

PARAMETER 1	CAUSE OF ERROR AND DEBUGGER MESSAGE
0x14	The driver called a DMA routine at an improper IRQL. The required IRQL and the actual IRQL are displayed.
0x15	The driver tried to allocate too many map registers. The number requested and the number allowed are displayed.
0x16	The driver tried to flush a buffer that is not mapped. The address of the buffer is displayed.
0x18	The driver tried a DMA operation by using an adapter that was already released and no longer exists. The adapter address is displayed.
0x19	The driver passed a null DMA_ADAPTER value to a HAL routine.
0x1B	The driver passed an address and MDL to a HAL routine. However, this address is not within the bounds of this MDL. The address passed and the address of the MDL are displayed.
0x1D	The driver tried to map an address range that was already mapped. The address range and the current mapping for that range are displayed.
0x1E	The driver called HalGetAdapter . This function is obsolete -- you must use IoGetDmaAdapter instead.
0x1F	HV_BAD_MDLThe driver referenced an invalid system address -- either before the first MDL, or after the end of the first MDL, or by using a transfer length that is longer than the MDL buffer and crosses a page boundary within the MDL. . Either the invalid address and the first MDL address, or the MDL address and the extra transfer length are displayed.
0x20	The driver tried to flush a map register that hasn't been mapped. The map register base, flushing address, and MDL are displayed.
0x21	The driver tried to map a zero-length buffer for transfer.

Cause

See the description of each code in the Parameters section for a description of the cause.

Resolution

This bug check can only occur when Driver Verifier has been instructed to monitor one or more drivers. If you did not intend to use Driver Verifier, you should deactivate it. You might also consider removing the driver that caused this problem.

If you are the driver writer, use the information obtained through this bug check to fix the bugs in your code.

The Driver Verifier **DMA Verification** option is only available in Windows XP and later versions. For full details on Driver Verifier, see the Windows Driver Kit.

Bug Check 0xE7: INVALID_FLOATING_POINT_STATE

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_FLOATING_POINT_STATE bug check has a value of 0x000000E7. This indicates that a thread's saved floating-point state is invalid.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_FLOATING_POINT_STATE Parameters

Parameter 1 indicates which validity check failed. Parameter 4 is not used. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	CAUSE OF ERROR
0x0	The flags field	0	The saved context flags field is invalid. Either FLOAT_SAVE_VALID is not set, or some reserved bits are nonzero.
0x1	The saved IRQL	The current IRQL	The current processor's IRQL is not the same as when the floating-point context was saved.
0x2	The saved address of the thread that owns this floating-point context	The current thread	The saved context does not belong to the current thread.

Cause

While restoring the previously-saved floating-point state for a thread, the state was found to be invalid.

Parameter 1 indicates which validity check failed.

Bug Check 0xE8: INVALID_CANCEL_OF_FILE_OPEN

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_CANCEL_OF_FILE_OPEN bug check has a value of 0x000000E8. This indicates that an invalid file object was passed to **IoCancelFileOpen**.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_CANCEL_OF_FILE_OPEN Parameters

PARAMETER	DESCRIPTION
1	The file object passed to IoCancelFileOpen
2	The device object passed to IoCancelFileOpen
3	Reserved
4	Reserved

Cause

The file object passed to **IoCancelFileOpen** is invalid. It should have reference of one. The driver that called **IoCancelFileOpen** is at fault.

Bug Check 0xE9: ACTIVE_EX_WORKER_THREAD_TERMINATION

5/26/2017 • 1 min to read • [Edit Online](#)

The ACTIVE_EX_WORKER_THREAD_TERMINATION bug check has a value of 0x000000E9. This indicates that an active executive worker thread is being terminated.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ACTIVE_EX_WORKER_THREAD_TERMINATION Parameters

PARAMETER	DESCRIPTION
1	The exiting ETHREAD
2	Reserved
3	Reserved
4	Reserved

Cause

An executive worker thread is being terminated without having gone through the worker thread rundown code. This is forbidden; work items queued to the **ExWorkerQueue** must not terminate their threads.

A stack trace should indicate the cause.

Bug Check 0xEA: THREAD_STUCK_IN_DEVICE_DRIVER

5/26/2017 • 2 min to read • [Edit Online](#)

The THREAD_STUCK_IN_DEVICE_DRIVER bug check has a value of 0x000000EA. This indicates that a thread in a device driver is endlessly spinning.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

THREAD_STUCK_IN_DEVICE_DRIVER Parameters

PARAMETER	DESCRIPTION
1	A pointer to the stuck thread object
2	A pointer to the DEFERRED_WATCHDOG object
3	A pointer to the offending driver name
4	In the kernel debugger: The number of times the "intercepted" bug check 0xEA was hit On the blue screen: 1

Cause

A device driver is spinning in an infinite loop, most likely waiting for hardware to become idle.

This usually indicates problem with the hardware itself, or with the device driver programming the hardware incorrectly. Frequently, this is the result of a bad video card or a bad display driver.

Resolution

Use the [.thread \(Set Register Context\)](#) command together with Parameter 1. Then use [kb \(Display Stack Backtrace\)](#) to find the location where the thread is stuck.

If the kernel debugger is already connected and running when Windows detects a time-out condition. Then **DbgBreakPoint** will be called instead of **KeBugCheckEx**. A detailed message will be printed to the debugger. See [Sending Output to the Debugger](#) for more information.

This message will include what would have been the bug check parameters. Because no actual bug check was issued, the [.bugcheck \(Display Bug Check Data\)](#) command will not be useful. The four parameters can also be retrieved from Watchdog's global variables by using **dd watchdog!g_WdBugCheckData L5**" on a 32-bit system, or **dq watchdog!g_WdBugCheckData L5**" on a 64-bit system.

Debugging this error in an interactive manner such as this will enable you to find an offending thread, set breakpoints in it, and then use **g (Go)** to return to the spinning code to debug it further.

On multiprocessor machines (OS build 3790 or earlier), you can hit a time out if the spinning thread is interrupted by a hardware interrupt and an ISR or DPC routine is running at the time of the bug check. This is because the time out's work item can be delivered and handled on the second CPU and the same time. If this occurs, you must look deeper at the offending thread's stack to determine the spinning code which caused the time out to occur. Use the [**dds \(Display Words and Symbols\)**](#) command to do this.

Bug Check 0xEB: DIRTY_MAPPED_PAGES_CONGESTION

5/26/2017 • 1 min to read • [Edit Online](#)

The DIRTY_MAPPED_PAGES_CONGESTION bug check has a value of 0x000000EB. This indicates that no free pages are available to continue operations.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DIRTY_MAPPED_PAGES_CONGESTION Parameters

PARAMETER	DESCRIPTION
1	The total number of dirty pages
2	The number of dirty pages destined for the page file
3	Windows Server 2003 only: The size of the nonpaged pool available at the time of the bug check (in pages) Windows Vista and later versions: Reserved
4	Windows Server 2003 only: The number of transition pages that are currently stranded Windows Vista and later versions: The most recent modified write error status

Cause

The file system driver stack has deadlocked and most of the modified pages are destined for the file system. Because the file system is non-operational, the system has crashed because none of the modified pages can be reused without losing data. Any file system or filter driver in the stack may be at fault.

To see general memory statistics, use the [!lvm 3](#) extension.

This bug check can occur for any of the following reasons:

- A driver has blocked, deadlocking the modified or mapped page writers. Examples of this include mutex deadlocks or accesses to paged out memory in file system drivers or filter drivers. This indicates a driver bug.

If Parameter 1 or Parameter 2 is large, this is a possibility. Use [!lvm 3](#).

- A storage driver is not processing requests. Examples of this are stranded queues and unresponsive drives. This indicates a driver bug.

If Parameter 1 or Parameter 2 is large, this is a possibility. Use [!process 0 7](#).

- Windows Server 2003 only: Not enough pool is available for the storage stack to write out modified pages. This indicates a driver bug.

If Parameter 3 is small, this is a possibility. Use **!vm** and **!poolused 2**.

Bug Check 0xEC: SESSION_HAS_VALID_SPECIAL_POOL_ON_EXIT

5/26/2017 • 1 min to read • [Edit Online](#)

The SESSION_HAS_VALID_SPECIAL_POOL_ON_EXIT bug check has a value of 0x000000EC. This indicates that a session unload occurred while a session driver still held memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SESSION_HAS_VALID_SPECIAL_POOL_ON_EXIT Parameters

PARAMETER	DESCRIPTION
1	The session ID
2	The number of special pool pages that are leaking
3	Reserved
4	Reserved

Cause

This error is caused by a session driver not freeing its special pool allocations prior to a session unload. This indicates a bug in win32k.sys, atmfd.dll, rdpdd.dll, or a video driver.

Bug Check 0xED: UNMOUNTABLE_BOOT_VOLUME

5/26/2017 • 1 min to read • [Edit Online](#)

The UNMOUNTABLE_BOOT_VOLUME bug check has a value of 0x000000ED. This indicates that the I/O subsystem attempted to mount the boot volume and it failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UNMOUNTABLE_BOOT_VOLUME Parameters

PARAMETER	DESCRIPTION
1	The device object of the boot volume
2	The status code from the file system that describes why it failed to mount the volume
3	Reserved
4	Reserved

(Developer Content) Bug Check 0xEF: CRITICAL_PROCESS_DIED

5/26/2017 • 2 min to read • [Edit Online](#)

The CRITICAL_PROCESS_DIED bug check has a value of 0x000000EF. This indicates that a critical system process died.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CRITICAL_PROCESS_DIED Parameters

PARAMETER	DESCRIPTION
1	The process object
2	Reserved
3	Reserved
4	Reserved

Resolution

Determining the cause of this issue typically requires the use of the debugger to gather additional information. Multiple dump files should be examined to see if this stop code has similar characteristics, such as the code that is running when the stop code appears.

For more information, see [Crash dump analysis using the Windows debuggers \(WinDbg\)](#), [Using the !analyze Extension](#) and [!analyze](#).

Use the event log to see if there are higher level events that occur leading up to this stop code.

These general troubleshooting tips may be helpful.

- If you recently added hardware to the system, try removing or replacing it. Or check with the manufacturer to see if any patches are available.
- If new device drivers or system services have been added recently, try removing or updating them. Try to determine what changed in the system that caused the new bug check code to appear.
- Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.
- Check with the manufacturer to see if an updated system BIOS or firmware is available.
- You can try running the hardware diagnostics supplied by the system manufacturer.

- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- Run a virus detection program. Viruses can infect all types of hard disks formatted for Windows, and resulting disk corruption can generate system bug check codes. Make sure the virus detection program checks the Master Boot Record for infections.
- Use the System File Checker tool to repair missing or corrupted system files. The System File Checker is a utility in Windows that allows users to scan for corruptions in Windows system files and restore corrupted files. Use the following command to run the System File Checker tool (SFC.exe).

```
SFC /scannow
```

For more information, see [Use the System File Checker tool to repair missing or corrupted system files](#).

- Look in **Device Manager** to see if any devices are marked with the exclamation point (!). Review the events log displayed in driver properties for any faulting driver. Try updating the related driver.

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

[Analyzing a Kernel-Mode Dump File with WinDbg](#)

Bug Check 0xF1: SCSI_VERIFIER_DETECTED_VIOLATION

5/26/2017 • 2 min to read • [Edit Online](#)

The SCSI_VERIFIER_DETECTED_VIOLATION bug check has a value of 0x000000F1. This is the bug check code for all Driver Verifier **SCSI Verification** violations.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SCSI_VERIFIER_DETECTED_VIOLATION Parameters

Parameter 1 identifies the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1000	First argument passed	Second argument passed	Reserved	The miniport driver passed bad arguments to ScsiPortInitialize .
0x1001	Delay, in microseconds	Reserved	Reserved	The miniport driver called ScsiPortStallExecution and specified a delay greater than 0.1 second, stalling the processor too long.
0x1002	Address of routine that took too long	Address of miniport's HW_DEVICE_EXTENSION	Duration of the routine, in microseconds	A miniport routine called by the port driver took longer than 0.5 second to execute. (0.5 seconds is the limit for most routines. However, the HwInitialize routine is allowed 5 seconds, and the FindAdapter routine is exempt.)

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1003	Address of miniport's HW_DEVICE_EXTENSION	Address of the SRB	Reserved	The miniport driver completed a request more than once.
0x1004	Address of the SRB	Address of miniport's HW_DEVICE_EXTENSION	Reserved	The miniport driver completed a request with an invalid SRB status.
0x1005	Address of miniport's HW_DEVICE_EXTENSION	Address of LOGICAL_UNIT_EXTENSION	Reserved	The miniport driver called ScsiPortNotification to ask for NextLuRequest , but an untagged request is still active.
0x1006	Address of miniport's HW_DEVICE_EXTENSION	Invalid virtual address	Reserved	<p>The miniport driver passed an invalid virtual address to ScsiPortGetPhysicalAddress.</p> <p>(This usually means the address supplied doesn't map to the common buffer area.)</p>
0x1007	Address of ADAPTER_EXTENSION	Address of miniport's HW_DEVICE_EXTENSION	Reserved	The reset hold period for the bus ended, but the miniport driver still has outstanding requests.
0x2001	Delay, in microseconds	Reserved	Reserved	The Storport miniport driver called StorPortStallExecution and specified a delay longer than 0.1 second, stalling the processor for an excessive length of time.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x2002	Reserved	Reserved	Reserved	<p>StorPortGetUncachedExtension was not called from the miniport driver's HwStorFindAdapter routine. The StorPortGetUncachedExtension routine can only be called from the miniport driver's HwStorFindAdapter routine and only for a bus-master adapter. A Storport miniport driver must set the SrbExtensionSize of the HW_INITIALIZATION_DATA (Storport) structure before calling StorPortGetUncachedExtension.</p>
0x2003	Reserved	Reserved	Reserved	<p>An invalid address was passed to the StorPortGetDeviceBase routine. The StorPortGetDeviceBase routine supports only those addresses that were assigned to the driver by the system Plug and Play (PnP) manager.</p>
0x2004	Reserved	Reserved	Reserved	The Storport miniport driver completed the same I/O request more than once.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x2005	Reserved	Reserved	Reserved	The Storport miniport driver passed an invalid virtual address to one of the StorPortReadxx or StorPortWritexx x routines. This usually means the address supplied doesn't map to the common buffer area. The specified <i>Register</i> or <i>Port</i> must be in mapped memory-space range returned by StorPortGetDeviceBase routine.

Cause

See the description of each code in the Parameters section for an explanation of the cause.

Resolution

This bug check can only occur when Driver Verifier has been instructed to monitor one or more drivers. If you did not intend to use Driver Verifier, you should deactivate it. You might consider removing the driver which caused this problem as well.

If you are the driver writer, use the information obtained through this bug check to fix the bugs in your code.

The Driver Verifier **SCSI Verification** option is available only in Windows XP and later. The Driver Verifier **Storport Verification** option is available only in Windows 7 and later. For full details on Driver Verifier, see the Windows Driver Kit.

Bug Check 0xF2: HARDWARE_INTERRUPT_STORM

5/26/2017 • 2 min to read • [Edit Online](#)

The HARDWARE_INTERRUPT_STORM bug check has a value of 0x000000F2. This indicates that the kernel detected an interrupt storm.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

HARDWARE_INTERRUPT_STORM Parameters

PARAMETER	DESCRIPTION
1	Address of the ISR (or first ISR in the chain) connected to the storming interrupt vector
2	ISR context value
3	Address of the interrupt object for the storming interrupt vector
4	0x1 if the ISR is not chained, 0x2 if the ISR is chained

Cause

This bugcheck indicates that the kernel has detected an interrupt storm. An interrupt storm is defined as a level triggered interrupt signal staying in the asserted state. This is fatal to the system in the manner that the system will hard hang, or "bus lock".

This can happen because of the following:

- A piece of hardware does not release its interrupt signal after being told to do so by the device driver.
- A device driver does not instruct its hardware to release the interrupt signal because it does not believe the interrupt was initiated from its hardware.
- A device driver claims the interrupt even though the interrupt was not initiated from its hardware. Note that this can only occur when multiple devices are sharing the same IRQ.
- The ELCR (edge level control register) is set incorrectly.
- Edge and Level interrupt triggered devices share an IRQ (e.g. COM port and PCI SCSI controller).

All of these cases will instantly hard hang your system. Instead of hard hanging the system, this bugcheck is initiated since in many cases it can identify the culprit.

When the bugcheck occurs, the module containing the ISR (interrupt service routine) of the storming IRQ is displayed on the screen. This is an example of what you would see:

```
*** STOP: 0x000000F2 (0xFCA7C55C, 0x817B9B28, 0x817D2AA0, 0x00000002)
An interrupt storm has caused the system to hang.
*** Address FCA7C55C base at FCA72000, Datestamp 3A72BDEF - ACPI.sys
```

In the event the fourth parameter is a 0x00000001, the module pointed to is very likely the culprit. Either the driver

is broken, or the hardware is malfunctioning.

In the event the fourth parameter is a 0x00000002, the module pointed to is the first ISR in the chain, and is never guaranteed to be the culprit.

Resolution

A user experiencing this bugcheck repeatedly should try to isolate the problem by looking for devices that are on the same IRQ as the one for which the module is a driver for (in this case, the same IRQ that ACPI is using).

Bug Check 0xF3: DISORDERLY_SHUTDOWN

5/26/2017 • 1 min to read • [Edit Online](#)

The DISORDERLY_SHUTDOWN bug check has a value of 0x000000F3. This indicates that Windows was unable to shut down due to lack of memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DISORDERLY_SHUTDOWN Parameters

PARAMETER	DESCRIPTION
1	The total number of dirty pages
2	The number of dirty pages destined for the page file
3	Windows Server 2003 only: The size of the nonpaged pool available at the time of the bug check (in pages) Windows Vista and later: Reserved
4	Windows Server 2003 only: The current shut down stage Windows Vista and later: The most recent modified write error status

Cause

Windows attempted to shut down, but there were no free pages available to continue operations.

Because applications were not terminated and drivers were not unloaded, they continued to access pages even after the modified writer had terminated. This causes the system to run out of pages, since the page files could be used.

Bug Check 0xF4: CRITICAL_OBJECT_TERMINATION

5/26/2017 • 1 min to read • [Edit Online](#)

The CRITICAL_OBJECT_TERMINATION bug check has a value of 0x000000F4. This indicates that a process or thread crucial to system operation has unexpectedly exited or been terminated.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CRITICAL_OBJECT_TERMINATION Parameters

PARAMETER	DESCRIPTION
1	The terminating object type: 0x3: Process 0x6: Thread
2	The terminating object
3	The process image file name
4	Pointer to an ASCII string containing an explanatory message

Cause

Several processes and threads are necessary for the operation of the system. When they are terminated for any reason, the system can no longer function.

Bug Check 0xF5: FLTMGR_FILE_SYSTEM

5/26/2017 • 2 min to read • [Edit Online](#)

The FLTMGR_FILE_SYSTEM bug check has a value of 0x000000F5. This indicates that an unrecoverable failure occurred in the Filter Manager.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

FLTMGR_FILE_SYSTEM Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x66	Pointer to the callback data structure for the operation.	0	0	The minifilter returned FLT_PREOP_SUCC_ESS_WITH_CALLBACK ACK or FLT_PREOP_SYNC_HRONIZE from a preoperation callback, but did not register a corresponding postoperation callback.
0x67	Pointer to the callback data structure for the operation.	0	Error NTSTATUS code for the operation	An internal object ran out of space, and the system is unable to allocate new space.
0x68	Reserved	Address of the FLT_FILE_NAME_INFORMATION structure	Reserved	A FLT_FILE_NAME_INFORMATION structure was dereferenced too many times.
0x6A	File object pointer for the file.	0	0	The file-open or file-create request could not be canceled, because one or more handles have been created for the file.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x6B	Frame ID	0	Thread	Invalid BACKPOCKET IRPCTRL state.
0x6C	Frame ID	BackPocket List	Thread	Too many nested PageFaults for BACKPOCKETED IRPCTR.
0x6D	Address of the minifilter's context structure	Address of the CONTEXT_NODE structure	0	The context structure was dereferenced too many times. This means that the reference count on the Filter Manager's CONTEXT_NODE structure went to zero while it was still attached to its associated object.
0x6E	Address of the minifilter's context structure	Address of the CONTEXT_NODE structure	0	The context structure was referenced after being freed.

Cause

The cause of the problem is indicated by the value of Parameter 1. See the table in the Parameters section.

Resolution

If Parameter 1 equals **0x66**, you can debug this problem by verifying that your minifilter driver has registered a post-operation callback for this operation. The current operation can be found in the callback data structure. (See Parameter 2.) Use the **!fltkd.cbd** debugger extension.

If Parameter 1 equals **0x67**, you should verify that you do not have a nonpaged pool leak somewhere in the system.

If Parameter 1 equals **0x6A**, make sure that your minifilter driver does not reference this file object (see Parameter 2) to get a handle at any point during your minifilter's processing of this operation.

If Parameter 1 equals **0x6B** or **0x6C**, then a non-recoverable internal state error has occurred which will cause the operating system to bug check.

If Parameter 1 equals **0x6D**, make sure that your minifilter driver does not call **FltReleaseContext** too many times for the given context (see Parameter 2).

If Parameter 1 equals 0x6E, make sure that your minifilter driver does not call **FltReferenceContext** after the given context has been deleted (see Parameter 2).

Bug Check 0xF6: PCI_VERIFIER_DETECTED_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The PCI_VERIFIER_DETECTED_VIOLATION bug check has a value of 0x000000F6. This indicates that an error occurred in the BIOS or another device being verified by the PCI driver.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PCI_VERIFIER_DETECTED_VIOLATION Parameters

Parameter 1 is the only parameter of interest; this identifies the nature of the failure detected.

PARAMETER 1	CAUSE OF ERROR
0x01	An active bridge was reprogrammed by the BIOS during a docking event.
0x02	The PMCSR register was not updated within the spec-mandated time.
0x03	A driver has written to Windows-controlled portions of a PCI device's configuration space.

Cause

The PCI driver detected an error in a device or BIOS being verified.

Bug Check 0xF7: DRIVER_OVERRAN_STACK_BUFFER

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_OVERRAN_STACK_BUFFER bug check has a value of 0x000000F7. This indicates that a driver has overrun a stack-based buffer.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_OVERRAN_STACK_BUFFER Parameters

PARAMETER	DESCRIPTION
1	The actual security check cookie from the stack
2	The expected security check cookie
3	The bit-complement of the expected security check cookie
4	0

Cause

A driver overran a stack-based buffer (or local variable) in a way that would have overwritten the function's return address and jumped back to an arbitrary address when the function returned.

This is the classic "buffer overrun" hacking attack. The system has been brought down to prevent a malicious user from gaining complete control of it.

Resolution

Use the [kb \(Display Stack Backtrace\)](#) command to get a stack trace.

The last routine on the stack before the buffer overrun handlers and bug check call is the one that overran its local variable.

Bug Check 0xF8: RAMDISK_BOOT_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The RAMDISK_BOOT_INITIALIZATION_FAILED bug check has a value of 0x000000F8. This indicates that an initialization failure occurred while attempting to boot from the RAM disk.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

RAMDISK_BOOT_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	<p>Indicates the cause of the failure.</p> <p>1: No LoaderXIPRom descriptor was found in the loader memory list.</p> <p>2: Unable to open the RAM disk driver (ramdisk.sys or \Device\Ramdisk).</p> <p>3: FSCTL_CREATE_RAM_DISK failed.</p> <p>4: Unable to create GUID string from binary GUID.</p> <p>5: Unable to create symbolic link pointing to the RAM disk device.</p>
2	NTSTATUS code
3	0
4	0

Bug Check 0xF9: DRIVER_RETURNED_STATUS_REPARSE_FOR_VOLUME_OPEN

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_RETURNED_STATUS_REPARSE_FOR_VOLUME_OPEN bug check has a value of 0x000000F9. This indicates that a driver returned STATUS_REPARSE to an IRP_MJ_CREATE request with no trailing names.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_RETURNED_STATUS_REPARSE_FOR_VOLUME_OPEN Parameters

PARAMETER	DESCRIPTION
1	The device object that was opened
2	The device object to which the IRP_MJ_CREATE request was issued
3	Address of the Unicode string containing the new name of the file (to be reparsed)
4	Information returned by the driver for the IRP_MJ_CREATE request

Remarks

STATUS_REPARSE should be returned only for IRP_MJ_CREATE requests with trailing names, as that indicates the driver is supporting name spaces.

Bug Check 0xFA: HTTP_DRIVER_CORRUPTED

5/26/2017 • 1 min to read • [Edit Online](#)

The HTTP_DRIVER_CORRUPTED bug check has a value of 0x000000FA. This indicates that the HTTP kernel driver (Http.sys) has reached a corrupted state and cannot recover.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

HTTP_DRIVER_CORRUPTED Parameters

Parameter 1 identifies the exact state of the HTTP kernel driver.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1	Address of work item	Name of the file that contains the work item check	Line number of the work item check within the file	A work item is invalid. This will eventually result in thread pool corruption and an access violation.

Bug Check 0xFC: ATTEMPTED_EXECUTE_OF_NOEXECUTE_MEMORY

5/26/2017 • 1 min to read • [Edit Online](#)

The ATTEMPTED_EXECUTE_OF_NOEXECUTE_MEMORY bug check has a value of 0x000000FC. This indicates that an attempt was made to execute non-executable memory.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ATTEMPTED_EXECUTE_OF_NOEXECUTE_MEMORY Parameters

PARAMETER	DESCRIPTION
1	The virtual address whose execution was attempted
2	The contents of the page table entry (PTE)
3	Reserved
4	Reserved

Resolution

When possible, the Unicode string of the driver name that attempted to execute non-executable memory is printed on the bug check screen and is also saved in **KiBugCheckDriver**. Otherwise, the driver in question can often be found by running a stack trace and then reviewing the current instruction pointer.

Bug Check 0xFD: DIRTY_NOWRITE_PAGES_CONGESTION

5/26/2017 • 1 min to read • [Edit Online](#)

The DIRTY_NOWRITE_PAGES_CONGESTION bug check has a value of 0x000000FD. This indicates that there are no free pages available to continue basic system operations.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DIRTY_NOWRITE_PAGES_CONGESTION Parameters

PARAMETER	DESCRIPTION
1	Total number of dirty pages
2	Number of non-writeable dirty pages
3	Reserved
4	Most recently modified write-error status

Cause

This bug check usually occurs because the component that owns the modified non-writeable pages failed to write out these pages after marking the relevant files as "do not write" to memory management. This indicates a driver bug.

Resolution

For more information about which driver is causing the problem, use the **!vm 3** extension, followed by **!memusage 1**.

Bug Check 0xFE: BUGCODE_USB_DRIVER

5/26/2017 • 2 min to read • [Edit Online](#)

The BUGCODE_USB_DRIVER bug check has a value of 0x000000FE. This indicates that an error has occurred in a universal serial bus (USB) driver.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BUGCODE_USB_DRIVER Parameters

Parameter 1 identifies the type of violation.

Parameter 1 Parameter 2 Parameter 3 Parameter 4 Cause of Error 0x1

Reserved

Reserved

Reserved

An internal error has occurred in the USB stack.

0x2

Address of the pending IRP

Address of the IRP that was passed in

Address of the USB request block (URB) that caused the error

The USB client driver has submitted a URB that is still attached to another IRP pending in the bus driver.

0x3

Reserved

Reserved

Reserved

The USB miniport driver has generated a bug check. This usually happens in response to a hardware failure.

0x4

Address of the IRP

Address of the URB

Reserved

The caller has submitted an IRP that is already pending in the USB bus driver.

0x5

Device extension pointer of the host controller

PCI vendor, product id for the controller

Pointer to endpoint data structure

A hardware failure has occurred because of a bad physical address found in a hardware data structure.

0x6

Object address

Signature that was expected

Reserved

An internal data structure (object) is corrupted.

0x7

Pointer to usbport.sys debug log

Message string

File name

Please see the provided message string for detailed information.

0x8

1

Reserved

Reserved

Reserved

2

Device object

IRP

An IRP was received by the hub driver that it does not expect or has not registered for.

3

Reserved

Reserved

Reserved

4

PDO if Parameter 3 is not NULL. Context if Parameter 3 is NULL.

Context or NULL

Fatal PDO trap

5

Reserved

Reserved

Reserved

6

Time-out code. See the following table.

Time-out code context: port data

Fatal time-out

If Parameter 1 has a value of 8 and Parameter 2 has a value of 6, then Parameter 3 is a time-out code. Possible values for the time-out code are given in the following table.

TIME-OUT CODE	MEANING
0	Non-fatal time-out
1	Failed resuming a suspended port.
2	Timed out waiting for a reset, initiated by a client driver, to complete before suspending the port.
3	Timed out waiting for the port to complete resume before suspending it.
4	Timed out waiting for the port-change state machine to be disabled prior to suspending the port.
5	Timed out waiting for a suspend-port request to complete.
6	Timed out waiting for the port-change state machine to be disabled.
7	Timed out waiting for the port-change state machine to be closed.
8	Timed out waiting for the hub to resume from selective suspend.
9	Timed out waiting for the hub to resume from selective suspend prior to system suspend.
10	Timed out waiting for port-change state machine to become idle.

Bug Check 0xFF: RESERVE_QUEUE_OVERFLOW

5/26/2017 • 1 min to read • [Edit Online](#)

The RESERVE_QUEUE_OVERFLOW bug check has a value of 0x000000FF. This indicates that an attempt was made to insert a new item into a reserve queue, causing the queue to overflow.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

RESERVE_QUEUE_OVERFLOW Parameters

PARAMETER	DESCRIPTION
1	The address of the reserve queue
2	The size of the reserve queue
3	0
4	0

Bug Check 0x100: LOADER_BLOCK_MISMATCH

5/26/2017 • 1 min to read • [Edit Online](#)

The LOADER_BLOCK_MISMATCH bug check has a value of 0x00000100. This indicates that either the loader block is invalid, or it does not match the system that is being loaded.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

LOADER_BLOCK_MISMATCH Parameters

PARAMETER	DESCRIPTION
1	3
2	The size of the loader block extension
3	The major version of the loader block
4	The minor version of the loader block

Bug Check 0x101: CLOCK_WATCHDOG_TIMEOUT

5/26/2017 • 1 min to read • [Edit Online](#)

The CLOCK_WATCHDOG_TIMEOUT bug check has a value of 0x00000101. This indicates that an expected clock interrupt on a secondary processor, in a multi-processor system, was not received within the allocated interval.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CLOCK_WATCHDOG_TIMEOUT Parameters

PARAMETER	DESCRIPTION
1	Clock interrupt time-out interval, in nominal clock ticks
2	0
3	The address of the processor control block (PRCB) for the unresponsive processor
4	0

Cause

The specified processor is not processing interrupts. Typically, this occurs when the processor is nonresponsive or is deadlocked.

Bug Check 0x102: DPC_WATCHDOG_TIMEOUT

5/26/2017 • 1 min to read • [Edit Online](#)

The DPC_WATCHDOG_TIMEOUT bug check has a value of 0x00000102. This indicates that The DPC watchdog routine was not executed within the allocated time interval.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DPC_WATCHDOG_TIMEOUT Parameters

PARAMETER	DESCRIPTION
1	DPC watchdog time out interval in nominal clock ticks.
2	The PRCB address of the hung processor.
3	Reserved
4	Reserved

Cause

This bug check typically means that either an ISR is hung at an IRQL that is below clock level and above dispatch level, or a DPC routine is hung on the specified processor.

For example for StorPort Miniport drivers, StorPort.sys handles I/O completions in a routine that runs at DISPATCH_LEVEL and that serially calls the I/O completion routines of all IRPs that have just completed. If I/O completion routines singly or together take too much time, the keyboard and/or mouse may stop responding. It is also possible that the Windows DPC Watchdog timer routine will decide that the StorPort routine has taken excessive time to finish.

Resolution

A kernel driver in the storage stack can reduce the problem's likelihood by efficient coding of the driver's I/O completion routine. If it is still not possible to do all necessary processing in the completion routine in enough time, the routine can create a work element for the I/O work, queue up the element to a work queue and return STATUS_MORE_PROCESSING_REQUIRED; a worker thread of the driver should then find the work element, do the work and do IoCallerDriver for the IRP to ensure the IRP's further I/O processing.

Bug Check 0x103: MUP_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The MUP_FILE_SYSTEM bug check has a value of 0x00000103. This bug check indicates that the multiple UNC provider (MUP) has encountered invalid or unexpected data. As a result, the MUP cannot channel a remote file system request to a network redirector, the Universal Naming Convention (UNC) provider.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MUP_FILE_SYSTEM Parameters

Parameter 1 identifies the type of violation.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1	The address of the pending IRP.	The address of the file object whose file context could not be found.	The address of the device object.	The MUP could not locate the file context that corresponds to a file object. This typically indicates that the MUP is seeing an I/O request for a file object for which MUP did not see a corresponding IRP_MJ_CREATE request. The likely cause of this bug check is a filter driver error.
0x2	The address of the expected file context.	The address that was actually retrieved from the file object.	Reserved	A file context is known to exist for the file object, but was not what was expected (for example, it might be NULL).

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x3	The address of the IRP context.	The IRP completion status code.	The driver object of the UNC provider that completed the IRP (might be NULL).	<p>The IRP completion status was unexpected or invalid.</p> <p>This bug check occurs only when you are using a Checked Build of Windows and should only be caused by file system filter drivers that are attached to legacy network redirectors. Legacy redirectors use FsRtlRegisterUncProvider to register with MUP. This bug check detects filter drivers that return an NTSTATUS that is not STATUS_SUCCESS in IRP_MJ_CLEANUP or IRP_MJ_CLOSE requests.</p>
0x4	Address of the IRP	Address of the file object	The file context for the file object	An I/O operation was started on a file object before the create request for the file object was completed.

Remarks

The MUP maintains context information on a per-file object basis for all file objects it handles.

Bug Check 0x104: AGP_INVALID_ACCESS

5/26/2017 • 1 min to read • [Edit Online](#)

The AGP_INVALID_ACCESS bug check has a value of 0x00000104. This indicates that the GPU wrote to a range of Accelerated Graphics Port (AGP) memory that had not previously been committed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

AGP_INVALID_ACCESS Parameters

PARAMETER	DESCRIPTION
1	Offset (in ULONG) within the AGP verifier page to the first ULONG data that is corrupted
2	0
3	0
4	0

Cause

Typically, this bug check is caused by an unsigned or improperly tested video driver. It can also be caused by an old BIOS.

Resolution

Check for display driver and computer BIOS updates.

Bug Check 0x105: AGP_GART_CORRUPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The AGP_GART_CORRUPTION bug check has a value of 0x00000105. This indicates that the Graphics Aperture Remapping Table (GART) is corrupt.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

AGP_GART_CORRUPTION Parameters

PARAMETER	DESCRIPTION
1	The base address (virtual) of the GART
2	The offset into the GART where the corruption occurred
3	The base address (virtual) of the GART cache (a copy of the GART)
4	0

Cause

This bug check is typically caused by improper direct memory access (DMA) by a driver.

Resolution

Enable Driver Verifier for any unsigned drivers. Remove them or disable them one by one until the erring driver is identified.

Bug Check 0x106: AGP_ILLEGALLY_REPROGRAMMED

5/26/2017 • 1 min to read • [Edit Online](#)

The AGP_ILLEGALLY_REPROGRAMMED bug check has a value of 0x00000106. This indicates that the Accelerated Graphics Port (AGP) hardware has been reprogrammed by an unauthorized agent.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

AGP_ILLEGALLY_REPROGRAMMED Parameters

PARAMETER	DESCRIPTION
1	The originally programmed AGP command register value
2	The current command register value
3	0
4	0

Cause

This bug check is typically caused by an unsigned, or improperly tested, video driver.

Resolution

Check the video manufacturer's Web site for updated display drivers or use VGA mode.

Bug Check 0x108: THIRD_PARTY_FILE_SYSTEM_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The THIRD_PARTY_FILE_SYSTEM_FAILURE bug check has a value of 0x00000108. This indicates that an unrecoverable problem has occurred in a third-party file system or file system filter.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

THIRD_PARTY_FILE_SYSTEM_FAILURE Parameters

PARAMETER	DESCRIPTION
1	Identifies the file system that failed. Possible values include: 1: Polyserve (Pvfs.sys)
2	The address of the exception record.
3	The address of the context record.
4	Reserved.

Cause

One possible cause of this bug check is disk corruption. Corruption in the third-party file system or bad blocks (sectors) on the hard disk can induce this error. Corrupted SCSI and IDE drivers can also adversely affect the Windows operating system's ability to read and write to disk, thus causing the error.

Another possible cause is depletion of nonpaged pool memory. If the nonpaged pool is completely depleted, this error can stop the system.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command with Parameter 3, and then use [.kb \(Display Stack Backtrace\)](#).

To resolve a disk corruption problem: Check Event Viewer for error messages from SCSI, IDE, or other disk controllers in the system that might help pinpoint the device or driver that is causing the error. Try disabling any virus scanners, backup programs, or disk defragmenter tools that continually monitor the system. You should also run hardware diagnostics supplied by the file system or the file system filter manufacturer.

To resolve a nonpaged pool memory depletion problem: Add new physical memory to the computer. This will increase the quantity of nonpaged pool memory available to the kernel.

Bug Check 0x109: CRITICAL_STRUCTURE_CORRUPTION

5/26/2017 • 3 min to read • [Edit Online](#)

The CRITICAL_STRUCTURE_CORRUPTION bug check has a value of 0x00000109. This indicates that the kernel has detected critical kernel code or data corruption.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CRITICAL_STRUCTURE_CORRUPTION Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	The type of the corrupted region. (See the following table later on this page.)

The value of Parameter 4 indicates the type of corrupted region.

PARAMETER 4	TYPE OF CORRUPTED REGION, TYPE OF CORRUPTION, OR TYPE OF ACTION TAKEN THAT CAUSED THE CORRUPTION
0x0	A generic data region
0x1	A function modification or the Itanium-based function location
0x2	A processor interrupt dispatch table (IDT)
0x3	A processor global descriptor table (GDT)
0x4	A type-1 process list corruption
0x5	A type-2 process list corruption
0x6	A debug routine modification

PARAMETER 4	TYPE OF CORRUPTED REGION, TYPE OF CORRUPTION, OR TYPE OF ACTION TAKEN THAT CAUSED THE CORRUPTION
0x7	A critical MSR modification
0x8	Object type
0x9	A processor IVT
0xA	Modification of a system service function
0xB	A generic session data region
0xC	Modification of a session function or .pdata
0xD	Modification of an import table
0xE	Modification of a session import table
0xF	Ps Win32 callout modification
0x10	Debug switch routine modification
0x11	IRP allocator modification
0x12	Driver call dispatcher modification
0x13	IRP completion dispatcher modification
0x14	IRP deallocator modification
0x15	A processor control register
0x16	Critical floating point control register modification
0x17	Local APIC modification
0x18	Kernel notification callout modification
0x19	Loaded module list modification

PARAMETER 4	TYPE OF CORRUPTED REGION, TYPE OF CORRUPTION, OR TYPE OF ACTION TAKEN THAT CAUSED THE CORRUPTION
0xA	Type 3 process list corruption
0xB	Type 4 process list corruption
0xC	Driver object corruption
0xD	Executive callback object modification
0xE	Modification of module padding
0xF	Modification of a protected process
0x20	A generic data region
0x21	A page hash mismatch
0x22	A session page hash mismatch
0x23	Load config directory modification
0x24	Inverted function table modification
0x25	Session configuration modification
0x26	An extended processor control register
0x27	Type 1 pool corruption
0x28	Type 2 pool corruption
0x29	Type 3 pool corruption
0x101	General pool corruption
0x102	Modification of win32k.sys

Cause

There are generally three different causes for this bug check:

1. A driver has inadvertently, or deliberately, modified critical kernel code or data. Microsoft Windows Server 2003 with Service Pack 1 (SP1) and later versions of Windows for x64-based computers do not allow the kernel to be patched except through authorized Microsoft-originated hot patches. For more information, see [Patching Policy for x64-based Systems](#).
2. A developer attempted to set a normal kernel breakpoint using a kernel debugger that was not attached when the system was started. Normal breakpoints (**bp**) can only be set if the debugger is attached at start time. Processor breakpoints (**ba**) can be set at any time.
3. A hardware corruption occurred. For example, the kernel code or data could have been stored in memory that failed.

Resolution

The **!analyze** debug extension displays information about the bug check and can be very helpful in determining the root cause.

To start, examine the stack trace using the **k, kb, kc, kd, kp, kP, kv (Display Stack Backtrace)** command. You can specify the processor number to examine the stacks on all processors.

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- Run the Windows Memory Diagnostics tool, to test the memory. In the control panel search box, type Memory, and then click **Diagnose your computer's memory problems**. After the test is run, use Event viewer to view the results under the System log. Look for the *MemoryDiagnostics-Results* entry to view the results.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- For additional general troubleshooting information, see [Blue Screen Data](#).

Bug Check 0x10A: APP_TAGGING_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The APP_TAGGING_INITIALIZATION_FAILED bug check has a value of 0x0000010A.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x10C: FSRTL_EXTRA_CREATE_PARAMETER_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The FSRTL_EXTRA_CREATE_PARAMETER_VIOLATION bug check has a value of 0x0000010C. This indicates that a violation was detected in the File system Run-time library (FsRtl) Extra Create Parameter (ECP) package.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

FSRTL_EXTRA_CREATE_PARAMETER_VIOLATION Parameters

PARAMETER	DESCRIPTION
1	The type of violation. (See the following table later on this page for more details).
2	0
3	The address of the ECP.
4	The starting address of the ECP list.

The value of Parameter 1 indicates the type of violation.

PARAMETER 1	TYPE OF VIOLATION
0x1	The ECP signature is invalid, due to either a bad pointer or memory corruption.
0x2	The ECP has undefined flags set.
0x3	The ECP was not allocated by the FsRtl.
0x4	The ECP has flags set that are illegal for a parameter passed by a create caller.
0x5	The ECP is corrupted; its size is smaller than the header size.
0x6	The ECP that is being freed has non-empty list pointers; it might still be part of an ECP list.

PARAMETER 1	TYPE OF VIOLATION
0x11	The ECP list signature is invalid, due to either a bad pointer or memory corruption.
0x12	The ECP list has undefined flags set.
0x13	The ECP list was not allocated by the FsRtl.
0x14	The ECP list has flags set that are illegal for a parameter list passed by a create caller.
0x15	The ECP list passed by the create caller is empty.

Bug Check 0x10D: WDF_VIOLATION

5/26/2017 • 4 min to read • [Edit Online](#)

The WDF_VIOLATION bug check has a value of 0x0000010D. This indicates that Kernel-Mode Driver Framework (KMDF) detected that Windows found an error in a framework-based driver.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WDF_VIOLATION Parameters

Parameter 1 indicates the specific error code of the bug check. Parameter 4 is reserved.

PARAMETER 1	PARAMETER 2	PARAMETER 3	CAUSE OF ERROR
0x1	Pointer to a WDF_POWER_ROUTINE_TIMED_OUT_DATA structure	Reserved	A framework-based driver has timed out during a power operation. This typically means that the device stack did not set the DO_POWER_PAGABLE bit and a driver attempted a pageable operation after the paging device stack was powered down.
0x2	Reserved	Reserved	An attempt is being made to acquire a lock that is currently being held.
0x3	WDFREQUEST handle	The number of outstanding references that remain on both buffers	Windows Driver Framework Verifier has encountered a fatal error. In particular, an I/O request was completed, but a framework request object cannot be deleted because there are outstanding references to the input buffer, the output buffer, or both.
0x4	Reserved	The caller's address	A NULL parameter was passed to a function that required a non- NULL value.

PARAMETER 1	PARAMETER 2	PARAMETER 3	CAUSE OF ERROR
0x5	The handle value passed in	Reserved	A framework object handle of the incorrect type was passed to a framework object method.
0x6			See table below.
0x7	The handle of the framework object	Reserved	A driver attempted to delete a framework object incorrectly by calling WdfObjectDereference to delete a handle instead of calling WdfObjectDelete .
0x8	The handle of the DMA transaction object	Reserved	An operation occurred on a DMA transaction object while it was not in the correct state.
0x9			Currently unused.
0xA	A pointer to a WDF_QUEUE_FATAL_ER ROR_DATA structure	Reserved	A fatal error has occurred while processing a request that is currently in the queue.
0xB			See table below.
0xC	WDFDEVICE handle	Pointer to new PnP IRP	A new state-changing PnP IRP arrived while the driver was processing another state-changing PnP IRP.
0xD	WDFDEVICE handle	Pointer to power IRP	A device's power policy owner received a power IRP that it did not request. There might be multiple power policy owners, but only one is allowed. A KMDF driver can change power policy ownership by calling WdfDeviceInitSetPowerPolicyOwnership .

PARAMETER 1	PARAMETER 2	PARAMETER 3	CAUSE OF ERROR
0xE	IRQL at which the event callback function was called.	IRQL at which the event callback function returned.	An event callback function did not return at the same IRQL at which it was called. The callback function changed the IRQL directly or indirectly (for example, by acquiring a spinlock, which raises IRQL to DISPATCH_LEVEL, but not releasing the spinlock).
0xF	Address of an event callback function.	Reserved	An event callback function entered a critical region, but it did not leave the critical region before returning.

Parameter 1 is equal to 0x6

If Parameter 1 is equal to 0x6, then a fatal error was made in handling a WDF request. In this case, Parameter 2 further specifies the type of fatal error that has been made, as defined by the enumeration WDF_REQUEST_FATAL_ERROR.

PARAMETER 2	PARAMETER 3	CAUSE OF ERROR
0x1	The address of the IRP	No more I/O stack locations are available to format the underlying IRP.
0x2	The WDF request handle value	An attempt was made to format a framework request object that did not contain an IRP.
0x3	The WDF request handle value	The driver attempted to send a framework request that has already been sent to an I/O target.
0x4	A pointer to a WDF_REQUEST_FATAL_ERROR_INF ORMATION_LENGTH_MISMATCH_ DATA structure that contains a pointer to the IRP, a WDF request handle value, an IRP major function, and the number of bytes attempted to be written	The driver has completed a framework request, but has written more bytes to the output buffer than are specified in the IRP.

Parameter 1 is equal to 0xB

If Parameter 1 is equal to 0xB, then an attempt to acquire or release a lock was invalid. In this case, Parameter 3 further specifies the error that has been made.

PARAMETER 2	PARAMETER 3	CAUSE OF ERROR
The handle value	0x0	A handle passed to WdfObjectAcquireLock or WdfObjectReleaseLock represents an object that does not support synchronization locks.
A WDF spin lock handle	0x1	The spin lock is being released by a thread that did not acquire it.

Cause

See the description of each code in the Parameters section for an explanation of the cause.

Resolution

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in gathering information, such as the faulting code module.

Typically, the WDF dump file will yield further information on the driver that caused this bug check. Use this command to look at the log file.

```
kd> !wdfkd.wdflogdump <WDF_Driver_Name>
```

If Parameter 1 is equal to **0x2**, examine the caller's stack to determine the lock in question.

If Parameter 1 is equal to **0x3**, the driver's Kernel-Mode Driver Framework error log will include details about the outstanding references.

If Parameter 1 is equal to **0x4**, use the [!analyze](#) command with the value of *Parameter 3* as its argument to determine which function requires a non-**NULL** parameter.

If Parameter 1 is equal to **0x7**, use the [!wdfkd.wdfhandle](#)*Parameter 2* extension command to determine the handle type.

If Parameter 1 is equal to **0xA**, then the WDF_QUEUE_FATAL_ERROR_DATA structure will indicate either the problematic request or the queue handle. It will also indicate the NTSTATUS, if not STATUS_SUCCESS, when available.

Bug Check 0x10E: VIDEO_MEMORY_MANAGEMENT_INTERNAL

5/26/2017 • 2 min to read • [Edit Online](#)

The VIDEO_MEMORY_MANAGEMENT_INTERNAL bug check has a value of 0x0000010E. This indicates that the video memory manager has encountered a condition that it is unable to recover from.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_MEMORY_MANAGEMENT_INTERNAL Parameters

Parameter 1 is the only parameter of interest; this identifies the exact violation. Values for Parameter 1 that do not appear in this table must be individually examined.

PARAMETER 1	CAUSE OF ERROR
0x1	An attempt was made to rotate a non-rotate range.
0x2	An attempt was made to destroy a non-empty process heap.
0x3	An attempt to unmap from an aperture segment failed.
0x4	A rotation in a must-succeed path failed.
0x5	A deferred command failed.
0x6	An attempt was made to reallocate resources for an allocation that was having its eviction canceled.
0x7	An invalid attempt was made to defer free usage.
0x8	The split direct memory access (DMA) buffer contains an invalid reference.
0x9	An attempt to evict an allocation failed.
0xA	An invalid attempt to use a pinned allocation was made.
0xB	A driver returned an invalid error code from <i>BuildPagingBuffer</i> .

PARAMETER 1	CAUSE OF ERROR
0xC	A resource leak was detected in a segment.
0xD	A segment is being used improperly.
0xE	An attempt to map an allocation into an aperture segment failed.
0xF	A driver returned an invalid error code from <i>AcquireSwizzlingRange</i> .
0x10	A driver returned an invalid error code from <i>ReleaseSwizzlingRange</i> .
0x11	An invalid attempt to use an aperture segment was made.
0x12	A driver overflowed the provided DMA buffer.
0x13	A driver overflowed the provided private data buffer.
0x14	An attempt to purge all segments failed.
0x15	An attempt was made to free a virtual address descriptor (VAD) that was still in the rotated state
0x16	A driver broke the guaranteed DMA buffer model contract.
0x17	An unexpected system command failure occurred.
0x18	An attempt to release a pinned allocation's resource failed.
0x19	A driver failed to patch a DMA buffer.
0x1A	The owner of a shared allocation was freed.
0x1B	An attempt was made to release an aperture range that is still in use.
0x25	The GPU attempted to write over an undefined area of the aperture.

Cause

This bug check is usually caused by a video driver behaving improperly.

Resolution

If the problem persists, check Windows Update for an updated video driver.

Bug Check 0x10F: RESOURCE_MANAGER_EXCEPTION_NOT_HANDLED

5/26/2017 • 1 min to read • [Edit Online](#)

The RESOURCE_MANAGER_EXCEPTION_NOT_HANDLED bug check has a value of 0x0000010F. This indicates that the kernel transaction manager detected that a kernel-mode resource manager has raised an exception in response to a direct call-back. The resource manager is in an unexpected and unrecoverable state.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

RESOURCE_MANAGER_EXCEPTION_NOT_HANDLED Parameters

PARAMETER	DESCRIPTION
1	The address of the exception record
2	The address of the context record
3	The address of the exception code
4	The address of the resource manager

Bug Check 0x111: RECURSIVE_NMI

5/26/2017 • 1 min to read • [Edit Online](#)

The RECURSIVE_NMI bug check has a value of 0x00000111. This bug check indicates that a non-maskable-interrupt (NMI) occurred while a previous NMI was in progress.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Remarks

This bug check occurs when there is an error in the system management interrupt (SMI) code, and an SMI interrupts an NMI and enables interrupts. Execution then continues with NMIs enabled, and another NMI interrupts the NMI in progress.

Bug Check 0x112: MSRPC_STATE_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The MSRPC_STATE_VIOLATION bug check has a value of 0x00000112. This indicates that the Msrpc.sys driver has initiated a bug check.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MSRPC_STATE_VIOLATION Parameters

Parameters 1 and 2 are the only parameters of interest. Parameter 1 indicates the state violation type; the value for Parameter 2 is determined by the value of Parameter 1.

PARAMETER 1	PARAMETER 2	CAUSE OF ERROR
0x01	The exception code	A non-continuable exception was continued by the caller.
0x02	The error	The advanced local procedure call (ALPC) returned an invalid error.
0x03	The session to the server	The caller unloaded the Microsoft remote procedure call (MSRPC) driver while it was still in use. It is likely that open binding handles remain.
0x04 and 0x05	The session to the server	An invalid close command was received from the ALPC.
0x06	The binding handle	An attempt was made to bind a remote procedure call (RPC) handle a second time.
0x07	The binding handle	An attempt was made to perform an operation on a binding handle that was not bound.
0x08	The binding handle	An attempt was made to set security information on a binding handle that was already bound.
0x09	The binding handle	An attempt was made to set an option on a binding handle that was already bound.

PARAMETER 1	PARAMETER 2	CAUSE OF ERROR
0x0A	The call object	An attempt was made to cancel an invalid asynchronous remote procedure call.
0x0B	The call object	An attempt was made to push on an asynchronous pipe call when it was not expected.
0x0C and 0x0E	The pipe object	An attempt was made to push on an asynchronous pipe without waiting for notification.
0x0F	The pipe object	An attempt was made to synchronously terminate a pipe a second time.
0x15	The object closest to the error	An RPC internal error occurred.
0x16	Reserved	Two causally ordered calls were issued in an order that cannot be enforced by the RPC.
0x17	The call object	A server manager routine did not unsubscribe from notifications prior to completing the call.
0x18	The async handle	An invalid operation on the asynchronous handle occurred.

Cause

The most common cause of this bug check is that the caller of the Msrpc.sys driver violated the state semantics for such a call.

Bug Check 0x113: VIDEO_DXGKRNL_FATAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_DXGKRNL_FATAL_ERROR bug check has a value of 0x00000113. This indicates that the Microsoft DirectX graphics kernel subsystem has detected a violation.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x114: VIDEO_SHADOW_DRIVER_FATAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_SHADOW_DRIVER_FATAL_ERROR bug check has a value of 0x00000114. This indicates that the shadow driver has detected a violation.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x115: AGP_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The AGP_INTERNAL bug check has a value of 0x00000115. This indicates that the accelerated graphics port (AGP) driver has detected a violation.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x116: VIDEO_TDR_ERROR

5/26/2017 • 6 min to read • [Edit Online](#)

The VIDEO_TDR_ERROR bug check has a value of 0x00000116. This indicates that an attempt to reset the display driver and recover from a timeout failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_TDR_ERROR Parameters

PARAMETER	DESCRIPTION
1	The pointer to the internal TDR recovery context, if available.
2	A pointer into the responsible device driver module (for example, the owner tag).
3	The error code of the last failed operation, if available.
4	Internal context dependent data, if available.

Cause

A common stability problem in graphics occurs when the system appears completely frozen or hung while processing an end-user command or operation. Usually the GPU is busy processing intensive graphics operations, typically during game-play. No screen updates occur, and users assume that their system is frozen. Users usually wait a few seconds and then reboot the system by pressing the power button. Windows tries to detect these problematic hang situations and dynamically recover a responsive desktop.

This process of detection and recovery is known as Timeout Detection and Recovery (TDR). The default timeout is 2 seconds. In the TDR process for video cards, the operating system's GPU scheduler calls the display miniport driver's [DxgkDdiResetFromTimeout](#) function to reinitialize the driver and reset the GPU.

During this process, the operating system tells the driver not to access the hardware or memory and gives it a short time for currently running threads to complete. If the threads do not complete within the timeout, then the system bug checks with 0x116 VIDEO_TDR_FAILURE. For more information, see [Thread Synchronization and TDR](#).

The system can also bug check with VIDEO_TDR_FAILURE if a number of TDR events occur in a short period of time, by default more than five TDRs in one minute.

If the recovery process is successful, a message will be displayed, indicating that the "Display driver stopped responding and has recovered."

For more information, see Timeout Detection and Recovery (TDR), [TDR Registry Keys](#) and [TDR changes in Windows 8](#) which are located in [Debugging Tips for the Windows Display Driver Model \(WDDM\)](#).

Resolution

The GPU is taking more time than permitted to display graphics to your monitor. This behavior can occur for one or more of the following reasons:

- You may need to install the latest updates for your display driver, so that it properly supports the TDR process.
- Hardware issues that impact the ability of the video card to operate properly, including:
 - Over-clocked components, such as the motherboard
 - Incorrect component compatibility and settings (especially memory configuration and timings)
 - Insufficient system cooling
 - Insufficient system power
 - Defective parts (memory modules, motherboards, etc.)
- Visual effects, or too many programs running in the background may be slowing your PC down so that the video card can not respond as necessary.

The **!analyze** debug extension displays information about the bug check and can be very helpful in determining the root cause.

```
1: kd> !analyze -v
*****
*                                Bugcheck Analysis
*
*****
VIDEO_TDR_FAILURE (116)
Attempt to reset the display driver and recover from timeout failed.
Arguments:
Arg1: fffffe000c2c404c0, Optional pointer to internal TDR recovery context (TDR_RECOVERY_CONTEXT).
Arg2: ffffff8016470c14c, The pointer into responsible device driver module (e.g. owner tag).
Arg3: ffffffc000009a, Optional error code (NTSTATUS) of the last failed operation.
Arg4: 0000000000000004, Optional internal context dependent data.

...
```

Also displayed will be the faulting module name

```
MODULE_NAME: nvlddmkm
IMAGE_NAME: nvlddmkm.sys
```

You can use the **!m (List Loaded Modules)** command to display information about the faulting driver, including the timestamp.

```
1: kd> !m nvlddmkm
Browse full module list
start          end            module name

```

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code, if you can consistently reproduce the stop code.

For more information see the following topics:

Crash dump analysis using the Windows debuggers (WinDbg)

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- Verify that all graphics related software such as DirectX and OpenGL are up to date, and any graphics intensive applications (such as games) are fully patched.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).

• Using Safe Mode

Consider using Safe Mode to help isolate this issue. Using Safe Mode loads only the minimum required drivers and system services during the Windows startup. To enter Safe Mode, use **Update and Security** in Settings. Select **Recovery->Advanced startup** to boot to maintenance mode. At the resulting menu, choose **Troubleshoot-> Advanced Options -> Startup Settings -> Restart**. After Windows restarts to the **Startup Settings** screen, select option, 4, 5 or 6 to boot to Safe Mode.

Safe Mode may be available by pressing a function key on boot, for example F8. Refer to information from the manufacturer for specific startup options.

- Run the Windows Memory Diagnostics tool, to test the memory. In the control panel search box, type Memory, and then click **Diagnose your computer's memory problems**. After the test is run, use Event viewer to view the results under the System log. Look for the *MemoryDiagnostics-Results* entry to view the results.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- For additional general troubleshooting information, see [Blue Screen Data](#).

Remarks

Hardware certification requirements

For information on requirements that hardware devices must meet when they implement TDR, refer to the WHCK documentation on *Device.Graphics...TDRResiliency*.

Bug Check 0x117: VIDEO_TDR_TIMEOUT_DETECTED

5/26/2017 • 5 min to read • [Edit Online](#)

The VIDEO_TDR_TIMEOUT_DETECTED bug check has a value of 0x00000117. This indicates that the display driver failed to respond in a timely fashion.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_TDR_TIMEOUT_DETECTED Parameters

PARAMETER	DESCRIPTION
1	The pointer to the internal TDR recovery context, if available.
2	A pointer into the responsible device driver module (for example, the owner tag).
3	The secondary driver-specific bucketing key.
4	Internal context dependent data, if available.

Cause

A common stability problem in graphics occurs when the system appears completely frozen or hung while processing an end-user command or operation. Usually the GPU is busy processing intensive graphics operations, typically during game-play. No screen updates occur, and users assume that their system is frozen. Users usually wait a few seconds and then reboot the system by pressing the power button. Windows tries to detect these problematic hang situations and dynamically recover a responsive desktop.

This process of detection and recovery is known as Timeout Detection and Recovery (TDR). The default timeout is 2 seconds. In the TDR process for video cards, the operating system's GPU scheduler calls the display miniport driver's [DxgkDdiResetFromTimeout](#) function to reinitialize the driver and reset the GPU.

If the recovery process is successful, a message will be displayed, indicating that the "Display driver stopped responding and has recovered."

For more information, see Timeout Detection and Recovery (TDR), [TDR Registry Keys](#) and [TDR changes in Windows 8](#) which are located in [Debugging Tips for the Windows Display Driver Model \(WDDM\)](#).

Resolution

The GPU is taking more time than permitted to display graphics to your monitor. This behavior can occur for one or more of the following reasons:

- You may need to install the latest updates for your display driver, so that it properly supports the TDR process.
- Hardware issues that impact the ability of the video card to operate properly, including:

- Over-clocked components, such as the motherboard
- Incorrect component compatibility and settings (especially memory configuration and timings)
- Insufficient system cooling
- Insufficient system power
- Defective parts (memory modules, motherboards, etc.)
- Visual effects, or too many programs running in the background may be slowing your PC down so that the video card can not respond as necessary.

The **!analyze** debug extension displays information about the bug check and can be very helpful in determining the root cause.

```
3: kd> !analyze -v
*****
*          Bugcheck Analysis
*
*****
VIDEO_TDR_TIMEOUT_DETECTED (117)
The display driver failed to respond in timely fashion.
(This code can never be used for a real bugcheck.)
Arguments:
Arg1: 8975d500, Optional pointer to internal TDR recovery context (TDR_RECOVERY_CONTEXT).
Arg2: 9a02381e, The pointer into responsible device driver module (e.g owner tag).
Arg3: 00000000, The secondary driver specific bucketing key.
Arg4: 00000000, Optional internal context dependent data.

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code, if you can consistently reproduce the stop code.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- Verify that all graphics related software such as DirectX and OpenGL are up to date, and any graphics

intensive applications (such as games) are fully patched.

- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).

- **Using Safe Mode**

Consider using Safe Mode to help isolate this issue. Using Safe Mode loads only the minimum required drivers and system services during the Windows startup. To enter Safe Mode, use **Update and Security** in Settings. Select **Recovery->Advanced startup** to boot to maintenance mode. At the resulting menu, choose **Troubleshoot-> Advanced Options -> Startup Settings -> Restart**. After Windows restarts to the **Startup Settings** screen, select option, 4, 5 or 6 to boot to Safe Mode.

Safe Mode may be available by pressing a function key on boot, for example F8. Refer to information from the manufacturer for specific startup options.

- Run the Windows Memory Diagnostics tool, to test the memory. In the control panel search box, type Memory, and then click **Diagnose your computer's memory problems**. After the test is run, use Event viewer to view the results under the System log. Look for the *MemoryDiagnostics-Results* entry to view the results.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- For additional general troubleshooting information, see [Blue Screen Data](#).

Remarks

Hardware certification requirements

For information on requirements that hardware devices must meet when they implement TDR, refer to the WHCK documentation on *Device.Graphics...TDRResiliency*.

Bug Check 0x119: VIDEO_SCHEDULER_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_SCHEDULER_INTERNAL_ERROR bug check has a value of 0x00000119. This indicates that the video scheduler has detected a fatal violation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_SCHEDULER_INTERNAL_ERROR Parameters

Parameter 1 is the only parameter of interest and identifies the exact violation.

PARAMETER 1	CAUSE OF ERROR
0x1	The driver has reported an invalid fence ID.
0x2	The driver failed upon the submission of a command.
0x3	The driver failed upon patching the command buffer.
0x4	The driver reported an invalid flip capability.

Bug Check 0x11A: EM_INITIALIZATION_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The EM_INITIALIZATION_FAILURE bug check has a value of 0x0000011A.

This bug check appears very infrequently.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x11B: DRIVER_RETURNED_HOLDING_CANCEL_LOCK

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_RETURNED_HOLDING_CANCEL_LOCK bug check has a value of 0x0000011B. This bug check indicates that a driver has returned from a *cancel* routine that holds the global cancel lock. This causes all later cancellation calls to fail, and results in either a deadlock or another bug check.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_RETURNED_HOLDING_CANCEL_LOCK Parameters

PARAMETER	DESCRIPTION
1	The address of the IRP that was canceled (might not be valid).
2	The address of the <i>cancel</i> routine.

Remarks

The cancel spin lock should have been released by the *cancel* routine.

The driver calls the IoCancelIrpIoCancelIrp function to cancel an individual I/O request packet (IRP). This function acquires the cancel spin lock, sets the cancel flag in the IRP, and then calls the *cancel* routine specified by the appropriate field in the IRP, if a routine was specified. The *cancel* routine is expected to release the cancel spin lock. If there is no *cancel* routine, the cancel spin lock is released.

Bug Check 0x11C: ATTEMPTED_WRITE_TO_CM_PROTECTED_STORAGE

5/26/2017 • 1 min to read • [Edit Online](#)

The ATTEMPTED_WRITE_TO_CM_PROTECTED_STORAGE bug check has a value of 0x00000011C. This bug check indicates that an attempt was made to write to the read-only protected storage of the configuration manager.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ATTEMPTED_WRITE_TO_CM_PROTECTED_STORAGE Parameters

PARAMETER	DESCRIPTION
1	Virtual address for the attempted write
2	PTE contents
3	Reserved
4	Reserved

Remarks

When it is possible, the name of the driver that is attempting the write operation is printed as a Unicode string on the bug check screen and then saved in KiBugCheckDriver.

Bug Check 0x11D: EVENT_TRACING_FATAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The EVENT_TRACING_FATAL_ERROR bug check has a value of 0x0000011D. This bug check indicates that the Event Tracing subsystem has encountered an unexpected fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x11E: TOO_MANY_RECURSIVE_FAULTS

5/26/2017 • 1 min to read • [Edit Online](#)

The TOO_MANY_RECURSIVE_FAULTS bug check has a value of 0x0000011E. This indicates that a file system has caused too many recursive faults under low resource conditions to be handled.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

TOO_MANY_RECURSIVE_FAULTS Parameters

None

Bug Check 0x11F: INVALID_DRIVER_HANDLE

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_DRIVER_HANDLE bug check has a value of 0x0000011F. This indicates that someone has closed the initial handle for a driver between inserting the driver object and referencing the handle.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_DRIVER_HANDLE Parameters

PARAMETER	DESCRIPTION
1	The handle value for the driver object.
2	The status returned trying to reference the object.
3	The address of the PDRIVER_OBJECT.
4	Reserved

Bug Check 0x120: BITLOCKER_FATAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The BITLOCKER_FATAL_ERROR bug check has a value of 0x00000120. This indicates that BitLocker drive encryption encountered a problem that it cannot recover from.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BITLOCKER_FATAL_ERROR Parameters

PARAMETER	DESCRIPTION
1	Type of problem
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x121: DRIVER_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVER_VIOLATION bug check has a value of 0x00000121. This bug check indicates that a driver has caused a violation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_VIOLATION Parameters

PARAMETER	DESCRIPTION
1	Describes the type of violation
2	Reserved
3	Reserved

Remarks

Use a kernel debugger and view the call stack to determine the name of the driver that caused the violation.

Bug Check 0x122: WHEA_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The WHEA_INTERNAL_ERROR bug check has a value of 0x00000122. This bug check indicates that an internal error in the Windows Hardware Error Architecture (WHEA) has occurred. Errors can result from a bug in the implementation of a platform-specific hardware error driver (PSHED) plug-in supplied by a vendor, the firmware implementation of error records, or the firmware implementation of error injection.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WHEA_INTERNAL_ERROR Parameters

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1	Size of memory	Error source count	0	Failed to allocate enough memory for all the error sources in the hardware error source table.
0x2	Number of processors	0	0	Failed to allocate enough memory for a WHEA information block for each processor.
0x5	Status	Phase (The initialization phase for the bug check)	0	WHEA failed to allocate enough memory for the error sources, or the error source enumeration failed.
0x6	Status	Phase	Error source type	Failed to initialize the error source (Parameter 4) during the phase specified by Parameter 3.
0x7	Status	0	0	Failed to allocate enough memory.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x8	Number of error sources	0	0	Failed to allocate enough memory for all the error source descriptors.
0x9	Error source type	Source ID	0	WHEA received an uncorrected error source from an invalid error source.
0xA	Error source type	Source ID	0	Failed to allocate an error record for an uncorrected error.
0xB	Error source type	Source ID	0	Failed to populate the error record for an uncorrected error.

If Parameter 1 is equal to 0x6, 0x9, 0xA, or 0xB, one of the other parameters contains the error source type. The following table gives possible values for the error source type.

VALUE	DESCRIPTION
0x00	Machine check exception
0x01	Corrected machine check
0x02	Corrected platform error
0x03	Non-maskable interrupt
0x04	PCI express error
0x05	Other types of error sources/Generic
0x06	IA64 INIT error source
0x07	BOOT error source
0x08	SCI-based generic error source
0x09	Itanium machine check abort
0x0A	Itanium machine check
0x0B	Itanium corrected platform error

Bug Check 0x123: CRYPTO_SELF_TEST_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The CRYPTO_SELF_TEST_FAILURE bug check has a value of 0x00000123. This indicates that the cryptographic subsystem failed a mandatory algorithm self-test during bootstrap.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CRYPTO_SELF_TEST_FAILURE Parameters

None

Bug Check 0x124: WHEA_UNCORRECTABLE_ERROR

5/26/2017 • 3 min to read • [Edit Online](#)

The WHEA_UNCORRECTABLE_ERROR bug check has a value of 0x00000124. This bug check indicates that a fatal hardware error has occurred. This bug check uses the error data that is provided by the Windows Hardware Error Architecture (WHEA).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WHEA_UNCORRECTABLE_ERROR Parameters

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x0	Address of WHEA_ERROR_RECORD structure.	High 32 bits of MCi_STATUS MSR for the MCA bank that had the error.	Low 32 bits of MCi_STATUS MSR for the MCA bank that had the error.	A machine check exception occurred. These parameter descriptions apply if the processor is based on the x64 architecture, or the x86 architecture that has the MCA feature available (for example, Intel Pentium Pro, Pentium IV, or Xeon).
0x1	Address of WHEA_ERROR_RECORD structure.	Reserved.	Reserved.	A corrected machine check exception occurred.
0x2	Address of WHEA_ERROR_RECORD structure.	Reserved.	Reserved.	A corrected platform error occurred.
0x3	Address of WHEA_ERROR_RECORD structure.	Reserved.	Reserved.	A nonmaskable Interrupt (NMI) error occurred.
0x4	Address of WHEA_ERROR_RECORD structure.	Reserved	Reserved.	An uncorrectable PCI Express error occurred.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x5	Address of WHEA_ERROR_RECORD structure.	Reserved.	Reserved.	A generic hardware error occurred.
0x6	Address of WHEA_ERROR_RECORD structure	Reserved.	Reserved.	An initialization error occurred.
0x7	Address of WHEA_ERROR_RECORD structure.	Reserved.	Reserved.	A BOOT error occurred.
0x8	Address of WHEA_ERROR_RECORD structure	Reserved.	Reserved.	A Scalable Coherent Interface (SCI) generic error occurred.
0x9	Address of WHEA_ERROR_RECORD structure.	Length, in bytes, of the SAL log.	Address of the SAL log.	An uncorrectable Itanium-based machine check abort error occurred.
0xA	Address of WHEA_ERROR_RECORD structure	Reserved.	Reserved.	A corrected Itanium-based machine check error occurred.
0xB	Address of WHEA_ERROR_RECORD structure.	Reserved.	Reserved.	A corrected Itanium platform error occurred.

Cause

This bug check is typically related to physical hardware failures. It can be heat related, defective hardware, memory or even a processor that is beginning to fail or has failed. If over-clocking has been enabled, try disabling it. Confirm that any cooling systems such as fans are functional. Run system diagnostics to confirm that the system memory is not defective. It is less likely, but possible that a driver is causing the hardware to fail with this bug check.

For additional general bug check troubleshooting information, see [Blue Screen Data](#).

Remarks

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in determining the root cause.

Parameter 1 identifies the type of error source that reported the error. Parameter 2 holds the address of the WHEA_ERROR_RECORD structure that describes the error condition.

When a hardware error occurs, WHEA creates an error record to store the error information associated with the hardware error condition. Each error record is described by a WHEA_ERROR_RECORD structure. The Windows kernel includes the error record with the Event Tracing for Windows (ETW) hardware error event that it raises in response to the error so that the error record is saved in the system event log. The format of the error records that are used by WHEA are based on the Common Platform Error Record as described in Appendix N of version 2.2 of the Unified Extensible Firmware Interface (UEFI) Specification. For more information, see [WHEA_ERROR_RECORD](#) and [Windows Hardware Error Architecture \(WHEA\)](#).

You can use **!errrec** <addr> to display the WHEA_ERROR_RECORD structure using the address provided in Parameter 2. The **!whea** and **!errpkt** extensions can be used to display additional WHEA information.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

[Analyzing a Kernel-Mode Dump File with WinDbg](#)

[Using the !analyze Extension and !analyze](#)

This bug check is not supported in Windows versions prior to Windows Vista. Instead, machine check exceptions are reported through [bug check 0x9C](#).

Bug Check 0x125: NMR_INVALID_STATE

5/26/2017 • 1 min to read • [Edit Online](#)

The NMR_INVALID_STATE bug check has a value of 0x000000125. This indicates that NMR (network module registrar) has detected an invalid state. See parameter 1 for the state type.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NMR_INVALID_STATE Parameters

PARAMETER	DESCRIPTION
-----------	-------------

PARAMETER	DESCRIPTION
1	<p>The subtype of the bugcheck.</p> <p>0x0 : Machine Check Exception</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>Parameter 3 - High order 32-bits of the MCi_STATUS value.</p> <p>Parameter 4 - Low order 32-bits of the MCi_STATUS value.</p> <p>0x1 : Corrected Machine Check</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x2 : Corrected Platform Error</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x3 : Non-maskable Interrupt</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x4 : PCI Express Error</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x5 : Generic Error</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x6 : INIT Error</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x7 : BOOT Error</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x8 : SCI Generic Error</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure.</p> <p>0x9 : Itanium Machine Check Abort</p> <p>Parameter 2 - Address of the WHEA_ERROR_RECORD structure. 2	Pointer to the NMI Handle
3	Pointer to the expected type, when available
4	Reserved

Bug Check 0x126: NETIO_INVALID_POOL_CALLER

5/26/2017 • 1 min to read • [Edit Online](#)

The NETIO_INVALID_POOL_CALLER bug check has a value of 0x00000126. This indicates that an invalid pool request has been made to netio managed memory pool, e.g. FSB and MDL.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

NETIO_INVALID_POOL_CALLER Parameters

PARAMETER	DESCRIPTION
1	<p>The subtype of the bugcheck.</p> <p>0x1 : Invalid pool. Pool is at an invalid state.</p> <p>Parameter 2 - Pointer to memory block or MDL. Parameter 3 - Pointer to page. Parameter 4 - Pointer to CPU pool.</p> <p>0x2 : Invalid MDL. MDL is at an invalid state.</p> <p>Parameter 2 - Pointer to MDL. Parameter 3 - Pointer to CPU pool. Parameter 4 - Pointer to pool header.</p>
2	See parameter 1
3	See parameter 1
4	See parameter 1

Bug Check 0x127: PAGE_NOT_ZERO

5/26/2017 • 1 min to read • [Edit Online](#)

The PAGE_NOT_ZERO bug check has a value of 0x00000127. This bug check indicates that a page that should have been filled with zeros was not. This bug check might occur because of a hardware error or because a privileged component of the operating system modified a page after freeing it.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PAGE_NOT_ZERO Parameters

PARAMETER	DESCRIPTION
1	Virtual address that maps the corrupted page
2	Physical page number
3	Zero (Reserved)
4	Zero (Reserved)

Bug Check 0x128: WORKER_THREAD_RETURNED_WITH_BAD_IO_PRIORITY

5/26/2017 • 1 min to read • [Edit Online](#)

The WORKER_THREAD_RETURNED_WITH_BAD_IO_PRIORITY bug check has a value of 0x00000128. This indicates that a worker threads IOPriority was wrongly modified by the called worker routine.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WORKER_THREAD_RETURNED_WITH_BAD_IO_PRIORITY Parameters

PARAMETER	DESCRIPTION
1	Address of worker routine (Use the In (List Nearest Symbols) command on this address to find the offending driver)
2	Current IoPriority value
3	Workitem parameter
4	Workitem address

Bug Check 0x129:

WORKER_THREAD_RETURNED_WITH_BAD_PAGING_IO_PRIORITY

5/26/2017 • 1 min to read • [Edit Online](#)

The WORKER_THREAD_RETURNED_WITH_BAD_PAGING_IO_PRIORITY bug check has a value of 0x00000129. This indicates that a worker threads Paging IOPriority was wrongly modified by the called worker routine.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WORKER_THREAD_RETURNED_WITH_BAD_PAGING_IO_PRIORITY Parameters

PARAMETER	DESCRIPTION
1	Address of worker routine Use the In (List Nearest Symbols) command on this address to find the offending driver.
2	Current Paging IoPriority value
3	Workitem parameter
4	Workitem address

Bug Check 0x12A: MUI_NO_VALID_SYSTEM_LANGUAGE

5/26/2017 • 1 min to read • [Edit Online](#)

The MUI_NO_VALID_SYSTEM_LANGUAGE bug check has a value of 0x0000012A. This indicates that Windows did not find any installed, licensed language packs for the system default UI language.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MUI_NO_VALID_SYSTEM_LANGUAGE Parameters

PARAMETER	DESCRIPTION
1	<p>The subtype of the bugcheck 0x1 : Windows did not find any installed language packs during phase I initialization.</p> <p>Parameter 2 - NT status code that describes the reason of failure. 0x2 : Windows did not find any installed, licensed language packs for the system default UI language during kernel cache creation.</p> <p>Parameter 2 - NT status code that describes the reason of failure. .</p>
2	See parameter 1
3	Reserved
4	Reserved

Bug Check 0x12B: FAULTY_HARDWARE_CORRUPTED_PAGE

5/26/2017 • 1 min to read • [Edit Online](#)

The FAULTY_HARDWARE_CORRUPTED_PAGE bug check has a value of 0x00000128. This bug check indicates that a single-bit error was found in this page. This is a hardware memory error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

FAULTY_HARDWARE_CORRUPTED_PAGE Parameters

PARAMETER	DESCRIPTION
1	Virtual address maps to the corrupted page
2	Physical page number
3	Zero (Reserved)
4	Zero (Reserved)

Bug Check 0x12C: EXFAT_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The EXFAT_FILE_SYSTEM bug check has a value of 0x0000012C. This bug check indicates that a problem occurred in the Extended File Allocation Table (exFAT) file system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

EXFAT_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	Specifies source file and line number information. The high 16 bits (the first four hexadecimal digits after the "0x") determine the source file by its identifier number. The low 16 bits determine the source line in the file where the bug check occurred.
2	If FppExceptionFilter is on the stack, this parameter specifies the address of the exception record.
3	If FppExceptionFilter is on the stack, this parameter specifies the address of the context record.
4	Reserved.

Cause

This bug check is caused by the file system as a last resort when its internal accounting is in an unsupportable state and to continue poses a large risk of data loss. The file system never causes this bug check when the on disk structures are corrupted, the disk sectors go bad, or a memory allocation fails. Bad sectors could lead to a bug check, for example, when a page fault occurs in kernel code or data and the memory manager cannot read the pages. However, for this bug check, the file system is not the cause.

Resolution

To debug this problem: Use the [.cxr \(Display Context Record\)](#) command together with Parameter 3, and then use [.kb \(Display Stack Backtrace\)](#).

Bug Check 0x12D: VOLSNAP_OVERLAPPED_TABLE_ACCESS

5/26/2017 • 1 min to read • [Edit Online](#)

The VOLSNAP_OVERLAPPED_TABLE_ACCESS bug check has a value of 0x0000012D. This indicates that volsnap tried to access a common table from two different threads which may result in table corruption and eventually corrupt the table.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VOLSNAP_OVERLAPPED_TABLE_ACCESS Parameters

None

Bug Check 0x12E: INVALID_MDL_RANGE

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_MDL_RANGE bug check has a value of 0x0000012E. This indicates that a driver has called the `IoBuildPartialMdl()` function and passed it an MDL to map part of a source MDL, but the virtual address range specified is outside the range in the source MDL. This is typically a driver bug.

The source and target MDLs, as well as the address range length to be mapped are the arguments to the `IoBuildPartialMdl()` function, i.e.:

```
IoBuildPartialMdl(
    IN PMDL SourceMdl,
    IN OUT PMDL TargetMdl,
    IN PVOID VirtualAddress,
    IN ULONG Length
```

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_MDL_RANGE Parameters

PARAMETER	DESCRIPTION
1	SourceMdl
2	TargetMdl
3	VirtualAddress
4	Length

Bug Check 0x12F: VHD_BOOT_INITIALIZATION_FAILED

5/26/2017 • 1 min to read • [Edit Online](#)

The VHD_BOOT_INITIALIZATION_FAILED bug check has a value of 0x0000012F. This indicates that an initialization failure occurred while attempting to boot from a VHD.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VHD_BOOT_INITIALIZATION_FAILED Parameters

PARAMETER	DESCRIPTION
1	Action that failed 1 : Couldn't extract VHD information from boot device. 2 : Timeout waiting for VHD parent device to surface. 3 : VHD path string memory allocation error. 4 : VHD path construction failed. 5 : VHD boot device mount failed. 6 : Disable sleep states failed. 7 : VHD information memory allocation error. 8 : VHD information construction failed.
2	NT status code
3	Reserved
4	Reserved

Bug Check 0x130: DYNAMIC_ADD_PROCESSOR_MISMATCH

5/26/2017 • 1 min to read • [Edit Online](#)

The DYNAMIC_ADD_PROCESSOR_MISMATCH bug check has a value of 0x00000130. This bugcheck indicates that a new processor added to the system is incompatible with the current configuration.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DYNAMIC_ADD_PROCESSOR_MISMATCH Parameters

None

Bug Check 0x131: INVALID_EXTENDED_PROCESSOR_STATE

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_EXTENDED_PROCESSOR_STATE bug check has a value of 0x00000131. This indicates that an invalid combination of parameters was detected while saving or restoring extended processor state.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_EXTENDED_PROCESSOR_STATE Parameters

Parameter one indicates which validity check failed.

PARAMETER	DESCRIPTION
1	0 - Invalid feature mask was passed or extended processor state is not enabled.
2	Nonzero if extended state is enabled.
3	The low 32 bits of the feature mask.
4	The high 32 bits of the feature mask.

PARAMETER	DESCRIPTION
1	1 - An attempt to save or restore extended state was made at IRQL higher than DISPATCH_LEVEL.
2	The IRQL
3	Reserved
4	Reserved

PARAMETER	DESCRIPTION
1	2 - The previously saved state is for an equal or higher level.
2	The saved level.
3	The current level.
4	Reserved

PARAMETER	DESCRIPTION
1	3 - The previously saved state is for a different thread.
2	The saved thread.
3	The current thread.
4	Reserved

PARAMETER	DESCRIPTION
1	4 - Previously saved state is for a different level.
2	The saved level.
3	The current level.
4	Reserved

Bug Check 0x132: RESOURCE_OWNER_POINTER_INVALID

5/26/2017 • 1 min to read • [Edit Online](#)

The RESOURCE_OWNER_POINTER_INVALID bug check has a value of 0x00000132. This indicates that an invalid resource owner pointer was supplied.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

RESOURCE_OWNER_POINTER_INVALID Parameters

PARAMETER	DESCRIPTION
1	Resource
2	Resource->OwnerTable
3	CurrentThread
4	OwnerPointer

Bug Check 0x133 DPC_WATCHDOG_VIOLATION

5/26/2017 • 3 min to read • [Edit Online](#)

The DPC_WATCHDOG_VIOLATION bug check has a value of 0x00000133. This bug check indicates that the DPC watchdog executed, either because it detected a single long-running deferred procedure call (DPC), or because the system spent a prolonged time at an interrupt request level (IRQL) of DISPATCH_LEVEL or above. The value of Parameter 1 indicates whether a single DPC exceeded a timeout, or whether the system cumulatively spent an extended period of time at IRQL DISPATCH_LEVEL or above. DPCs should not run longer than 100 microseconds and ISRs should not run longer than 25 microseconds, however the actual timeout values on the system are set much higher.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DPC_WATCHDOG_VIOLATION Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of *Parameter 1*.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0	The DPC time count (in ticks)	The DPC time allotment (in ticks).	Reserved	A single DPC or ISR exceeded its time allotment. The offending component can usually be identified with a stack trace.
1	The watchdog period	Reserved	Reserved	The system cumulatively spent an extended period of time at IRQL DISPATCH_LEVEL or above. The offending component can usually be identified with a stack trace.

Cause

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in determining the root cause.

Parameter 1 = 0

In this example, the tick count of 501 exceeds the DPC time allotment of 500. The image name indicates that this code was executing when the bug check occurred.

```

0: kd> !analyze -v
*****
*                               Bugcheck Analysis
*
*****
DPC_WATCHDOG_VIOLATION (133)
The DPC watchdog detected a prolonged run time at an IRQL of DISPATCH_LEVEL
or above.
Arguments:
Arg1: 0000000000000000, A single DPC or ISR exceeded its time allotment. The offending
      component can usually be identified with a stack trace.
Arg2: 00000000000501, The DPC time count (in ticks).
Arg3: 00000000000500, The DPC time allotment (in ticks).
Arg4: 0000000000000000

...
IMAGE_NAME:  BthA2DP.sys
...

```

Use the following debugger commands to gather more information for failures with a parameter of 0:

k (Display Stack Backtrace) to look at what code was running when the stop code occurred.

You may want to use the u, ub, uu (Unassemble) command to look deeper into the specifics of the code that was running.

The **!pcr** extension displays the current status of the Processor Control Region (PCR) on a specific processor. In the output will be the address of the Prcb

```

Prcb: fffff80309974180

```

You can use the **dt (Display Type)** command to display additional information about the DPCs and the DPC Watchdog. For the address use the Prcb listed in the **!pcr** output:

```

dt nt!_KPRCB fffff80309974180 Dpc*

```

Parameter 1 = 1

For parameter of 1, the code may not stop in the offending area of code. In this case one approach is to use the event tracing to attempt to track down which driver is exceeding its normal execution duration.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

[Analyzing a Kernel-Mode Dump File with WinDbg](#)

[Using the !analyze Extension and !analyze](#)

Remarks

In general this stop code is caused by faulty driver code that under certain conditions, does not complete its work within the allotted time frame.

If you are not equipped to use the Windows debugger to this problem, you should use some basic troubleshooting techniques.

- If a driver is identified in the bug check message, to isolate the issue, disable the driver. Check with the manufacturer for driver updates.
- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing bug check 0x133.
- Confirm that any new hardware that is installed is compatible with the installed version of Windows. For example, you can get information about required hardware at [Windows 10 Specifications](#).
- For additional general troubleshooting information, see **Blue Screen Data**.

Bug Check 0x134: DRIVE_EXTENDER

5/26/2017 • 1 min to read • [Edit Online](#)

The DRIVE_EXTENDER bug check has a value of 0x00000134. This indicates that the drive extender component has experienced a severe internal error that prevents continued system operation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVE_EXTENDER Parameters

None

Bug Check 0x135: REGISTRY_FILTER_DRIVER_EXCEPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The REGISTRY_FILTER_DRIVER_EXCEPTION bug check has a value of 0x00000135. This bugcheck is caused by an unhandled exception in a registry filtering driver.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

REGISTRY_FILTER_DRIVER_EXCEPTION Parameters

PARAMETER	DESCRIPTION
1	Exception Code
2	Address of the context record for the exception that caused the bugcheck
3	The driver's callback routine address
4	Reserved

Cause

This bugcheck indicates that a registry filtering driver didn't handle an exception inside its notification routine.

Resolution

Identify the offending driver by using the 3rd parameter.

Bug Check 0x136: VHD_BOOT_HOST_VOLUME_NOT_ENOUGH_SPACE

5/26/2017 • 1 min to read • [Edit Online](#)

The VHD_BOOT_HOST_VOLUME_NOT_ENOUGH_SPACE bug check has a value of 0x00000136. This indicates that an initialization failure occurred while attempting to boot from a VHD. The volume that hosts the VHD does not have enough free space to expand the VHD.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VHD_BOOT_HOST_VOLUME_NOT_ENOUGH_SPACE Parameters

PARAMETER	DESCRIPTION
1	0 : Unable to expand VHD file to full size.
2	NT Status Code
3	Reserved
4	Reserved

Bug Check 0x137: WIN32K_HANDLE_MANAGER

5/26/2017 • 1 min to read • [Edit Online](#)

The WIN32K_HANDLE_MANAGER bug check has a value of 0x00000137. This indicates that the win32k/ntuser handle manager has detected a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WIN32K_HANDLE_MANAGER Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Address of the object (If available)
3	Reserved
4	Reserved

Under some circumstances, additional parameters not listed here may be returned.

Bug Check 0x138: GPIO_CONTROLLER_DRIVER_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The GPIO_CONTROLLER_DRIVER_ERROR bug check has a value of 0x00000138. This bug check indicates that the GPIO class extension driver encountered a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

GPIO_CONTROLLER_DRIVER_ERROR Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of *Parameter 1*.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
1	GSIV	Reserved	Reserved	The GPIO controller managing the specific GSIV is not registered.
2	Context value	Reserved	Reserved	A client driver specified an invalid context to a lock or unlock request.
3	Indicates whether a critical transition is being requested.	Indicates whether the bank is already in F1 due to a non-critical transition.	Indicates whether the bank is already in F1 due to a critical transition.	PoFx requested that the GPIO controller send a bank through an inappropriate F1 power state and/or a critical transition.
4	Indicates whether a critical transition is being requested.	Indicates whether the bank is in F1 due to a non-critical transition.	Indicates whether the bank is in F1 due to a critical transition.	PoFx requested that the GPIO controller send a bank through an inappropriate F0 power state and/or a critical transition.
5	NTSTATUS	GPIO device extension	GPIO interrupt parameters	An on-Soc GPIO interrupt operation failed.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
6	NTSTATUS	GPIO device extension	GPIO IO parameters	An on-Soc GPIO IO operation failed.
7	Revision ID	Function Index	Reserved	A _DSM method returned malformed data.

Bug Check 0x139: KERNEL_SECURITY_CHECK_FAILURE

5/26/2017 • 5 min to read • [Edit Online](#)

The KERNEL_SECURITY_CHECK_FAILURE bug check has a value of 0x00000139. This bug check indicates that the kernel has detected the corruption of a critical data structure.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x139 KERNEL_SECURITY_CHECK_FAILURE Parameters

PARAMETER	DESCRIPTION
1	The type of corruption. For more information, see the following table.
2	Address of the trap frame for the exception that caused the bug check
3	Address of the exception record for the exception that caused the bug check
4	Reserved

The following table describes possible values for Parameter 1.

PARAMETER 1	DESCRIPTION
0	A stack-based buffer has been overrun (legacy /GS violation).
1	VTGuard instrumentation code detected an attempt to use an illegal virtual function table. Typically, a C++ object was corrupted, and then a virtual method call was attempted using the corrupted object's this pointer.
2	Stack cookie instrumentation code detected a stack-based buffer overrun (/GS violation).
3	A LIST_ENTRY was corrupted (for example, a double remove). For more information, see the following Cause section.
4	Reserved
5	An invalid parameter was passed to a function that considers invalid parameters fatal.

PARAMETER 1	DESCRIPTION
6	The stack cookie security cookie was not properly initialized by the loader. This may be caused by building a driver to run only on Windows 8 and attempting to load the driver image on an earlier version of Windows. To avoid this problem, you must build the driver to run on an earlier version of Windows.
7	A fatal program exit was requested.
8	A array bounds check inserted by the compiler detected an illegal array indexing operation.
9	A call to RtlQueryRegistryValues was made specifying RTL_QUERY_REGISTRY_DIRECT without RTL_QUERY_REGISTRY_TYPECHECK, and the target value was not in a trusted system hive.

Cause

Using the parameter 1 table, and a dump file, it is possible to narrow down the cause for many bug checks of this type.

LIST_ENTRY corruption can be difficult to track down and this bug check, indicates that an inconsistency has been introduced into a doubly-linked list (detected when an individual list entry element is added to or removed from the list). Unfortunately, the inconsistency is not necessarily detected at the time when the corruption occurred, so some detective work may be necessary to identify the root cause.

Common causes of list entry corruption include:

- A driver has corrupted a kernel synchronization object, such as a KEVENT (for example double initializing a KEVENT while a thread was still waiting on that same KEVENT, or allowing a stack-based KEVENT to go out of scope while another thread was using that KEVENT). This type of bug check typically occurs in nt!Ke* or nt!Ki* code. It can happen when a thread finishes waiting on a synchronization object or when code attempts to put a synchronization object in the signaled state. Usually, the synchronization object being signaled is the one that has been corrupted. Sometimes, Driver Verifier with special pool can help track down the culprit (if the corrupted synchronization object is in a pool block that has already been freed).
- A driver has corrupted a periodic KTIMER. This type of bug check typically occurs in nt!Ke* or nt!Ki* code and involves signaling a timer, or inserting or removing a timer from a timer table. The timer being manipulated may be the corrupted one, but it might be necessary to inspect the timer table with **!timer** (or manually walking the timer list links) to identify which timer has been corrupted. Sometimes, Driver Verifier with special pool can help track down the culprit (if the corrupted KTIMER is in a pool block that has already been freed).
- A driver has mismanaged an internal LIST_ENTRY-style linked list. A typical example would be calling **RemoveEntryList** twice on the same list entry without reinserting the list entry between the two **RemoveEntryList** calls. Other variations are possible, such as double inserting an entry into the same list.
- A driver has freed a data structure that contains a LIST_ENTRY without removing the data structure from its corresponding list, causing corruption to be detected later when the list is examined after the old pool block has been reused.
- A driver has used a LIST_ENTRY-style list in a concurrent fashion without proper synchronization, resulting in a torn update to the list.

In most cases, you can identify the corrupted data structure by walking the linked list both forward and backwards (the **dl** and **dlb** commands are useful for this purpose) and comparing the results. Where the list is inconsistent between a forward and backward walk is typically the location of the corruption. Since a linked list update

operation can modify the list links of a neighboring element, you should look at the neighbors of a corrupted list entry closely, as they may be the underlying culprit.

Because many system components internally utilize LIST_ENTRY lists, various types of resource mismanagement by a driver using system APIs might cause linked list corruption in a system-managed linked list.

Resolution

Determining the cause of this issues typically requires the use of the debugger to gather additional information. Multiple dump files should be examined to see if this stop code has similar characteristics, such as the code that is running when the stop code appears.

For more information, see [Crash dump analysis using the Windows debuggers \(WinDbg\)](#), [Using the !analyze Extension](#) and [!analyze](#).

Use the event log to see if there are higher level events that occur leading up to this stop code.

These general troubleshooting tips may be helpful.

- If you recently added hardware to the system, try removing or replacing it. Or check with the manufacturer to see if any patches are available.
- If new device drivers or system services have been added recently, try removing or updating them. Try to determine what changed in the system that caused the new bug check code to appear.
- Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.
- Look in **Device Manager** to see if any devices are marked with the exclamation point (!). Review the events log displayed in driver properties for any faulting driver. Try updating the related driver.
- Run a virus detection program. Viruses can infect all types of hard disks formatted for Windows, and resulting disk corruption can generate system bug check codes. Make sure the virus detection program checks the Master Boot Record for infections.
- For additional general troubleshooting information, see [Blue Screen Data](#).

Bug Check 0x13A: KERNEL_MODE_HEAP_CORRUPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_MODE_HEAP_CORRUPTION bug check has a value of 0x0000013A. This indicates that the kernel mode heap manager has detected corruption in a heap.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_MODE_HEAP_CORRUPTION Parameters

PARAMETER	DESCRIPTION
1	Type of corruption detected 0x3 : A corrupt entry header was detected. 0x4 : Multiple corrupt entry headers were detected. 0x5 : A corrupt entry header in a large allocation was detected. 0x6 : A corruption was detected with features consistent with a buffer overrun. 0x7 : A corruption was detected with features consistent with a buffer underrun. 0x8 : A free block was passed to an operation that is only valid for busy blocks. 0x9 : An invalid argument was specified for the current operation. 0xA : A corruption was detected with features consistent with a use-after-free error. 0xB : The wrong heap was specified for the current operation. 0xC : A corrupt free list was detected. 0xD : The heap detected list corruption in a list other than the free list.
2	Address of the heap that reported the corruption
3	Address at which the corruption was detected
4	Reserved

Bug Check 0x13B: PASSIVE_INTERRUPT_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The PASSIVE_INTERRUPT_ERROR bug check has a value of 0x0000013B. This indicates that the kernel has detected issues with the passive-level interrupt.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PASSIVE_INTERRUPT_ERROR Parameters

PARAMETER	DESCRIPTION
1	Type of error detected 0x1 : A driver tried to acquire an interrupt spinlock but passed in a passive-level interrupt object.
2	Address of the KINTERRUPT object for the passive-level interrupt.
3	Reserved
4	Reserved

Bug Check 0x13C: INVALID_IO_BOOST_STATE

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_IO_BOOST_STATE bug check has a value of 0x0000013C. This indicates that a thread exited with an invalid I/O boost state. This should be zero when a thread exits.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_IO_BOOST_STATE Parameters

PARAMETER	DESCRIPTION
1	Pointer to the thread which had the invalid boost state
2	Current boost state or throttle count
3	Reserved
4	Reserved

Bug Check 0x13D: CRITICAL_INITIALIZATION_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The CRITICAL_INITIALIZATION_FAILURE bug check has a value of 0x0000013D. This indicates that early kernel initialization has failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CRITICAL_INITIALIZATION_FAILURE Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x140: STORAGE_DEVICE_ABNORMALITY_DETECTED

5/26/2017 • 1 min to read • [Edit Online](#)

The STORAGE_DEVICE_ABNORMALITY_DETECTED bug check has a value of 0x00000140. This indicates that the storage driver stack encountered rate of responsiveness violations, exceeding the threshold, or other failures to respond.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

STORAGE_DEVICE_ABNORMALITY_DETECTED Parameters

None

Bug Check 0x141: VIDEO_ENGINETIMEOUT_DETECTED

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_ENGINETIMEOUT_DETECTED bug check has a value of 0x00000141. This indicates that one of the display engines failed to respond in timely fashion.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_ENGINETIMEOUT_DETECTED Parameters

PARAMETER	DESCRIPTION
1	Optional pointer to internal TDR recovery context (TDR_RECOVERY_CONTEXT).
2	The pointer into responsible device driver module (e.g owner tag).
3	The secondary driver specific bucketing key.
4	Optional internal context dependent data.

Remarks

Secondary data of tag {270A33FD-3DA6-460D-BA89-3C1BAE21E39B} contains additional TDR related data. Use .enumtag to view the data.

Bug Check 0x142: VIDEO_TDR_APPLICATION_BLOCKED

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_TDR_APPLICATION_BLOCKED bug check has a value of 0x00000142. This indicates that an application has been blocked from accessing graphics hardware.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_TDR_APPLICATION_BLOCKED Parameters

PARAMETER	DESCRIPTION
1	Optional pointer to internal TDR recovery context (TDR_RECOVERY_CONTEXT).
2	The pointer into responsible device driver module (e.g owner tag).
3	The secondary driver specific bucketing key.
4	Id of the process being blocked from accessing the GPU.

Remarks

Secondary data of tag {270A33FD-3DA6-460D-BA89-3C1BAE21E39B} contains additional TDR related data. Use [.enumtag \(Enumerate Secondary Callback Data\)](#) to view the data.

Bug Check 0x143: PROCESSOR_DRIVER_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The PROCESSOR_DRIVER_INTERNAL bug check has a value of 0x00000143. This indicates that the Processor Power Management (PPM) driver encountered a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PROCESSOR_DRIVER_INTERNAL Parameters

PARAMETER	DESCRIPTION
1	1 - Power Engine Plugin(PEP) failed to accept a required notification
2	PEP runtime Notification type
3	Pointer to notification message
4	Pointer to processor device context (FDO_DATA) issuing the notification
PARAMETER	DESCRIPTION
1	2 - Power Engine Plugin (PEP) returned invalid processor idle state
2	Type of invalid state 0x0 : PEP requested too many processors for coordinated idle state Parameter 3 - Number of processors requested to participate in coordinated idle transitions Parameter 4 - Pointer to processor device context (FDO_DATA) 0x1 : PEP requested processor to be in an invalid idle state Parameter 3 - Idle state index requested Parameter 4 - Pointer to processor device context (FDO_DATA) corresponding to the invalid idle state 0x2 : PEP requested the platform to be in an invalid idle state Parameter 3 - Platform idle state index requested Parameter 4 - Pointer to processor device context (FDO_DATA) corresponding to the invalid idle state
3	Refer to parameter 2
4	Refer to parameter 2

Cause

The processor driver detected an irreconcilable condition which prompted it to bugcheck. This likely happens during the processor idle and perf-state change execution, which may involve other entities such as kernel, HAL and the Power Engine Plugin (PEP). Information from bugcheck will help identify which of the assumptions made by the processor driver in dealing with other entities was violated. The root cause may lie in other entities and a dump file may reveal more information to ascertain the reason for the bugcheck.

Bug Check 0x144: BUGCODE_USB3_DRIVER

5/26/2017 • 6 min to read • [Edit Online](#)

The **BUGCODE_USB3_DRIVER** bug check has a value of 0x00000144. This is the code used for all USB 3 bug checks. Parameter 1 specifies the type of the USB 3 bug check, and the meanings of the other parameters are dependent on Parameter 1.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BUGCODE_USB3_DRIVER Parameters

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1	Optional. Pointer to the IRP used to resend the URB	Pointer to the URB	Pointer to the client driver's device object	A client driver used an URB that it had previously sent to the core stack.
0x2	Pointer to the physical device object (PDO) for the boot device	Reserved	Reserved	A boot or paging device failed re-enumeration.
0x3	Optional. Pointer to the IRP used to send the URB	Pointer to the corrupted URB	Pointer to the client driver's device object	A client driver sent a corrupted URB to the core stack. This can happen because the client driver did not allocate the URB using USBD_xxxUrbAlloc or because the client driver did a buffer underrun for the URB.
0x800	IRQL at which the Open Static Streams request was sent	Pointer to the Open Static Streams IRP	Pointer to the client driver's device object	An Open Static Streams request was sent at IRQL > PASSIVE LEVEL.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x801	Pointer to the Open Static Streams IRP	Pointer to the Open Static Streams URB	Pointer to the client driver's device object	A client driver attempted to open static streams before querying for streams capability. A client driver cannot open a static stream until after it successfully queries for the streams capability. For more information, see Remarks.
0x802	Number of static streams that the client driver tried to open	Number of static streams that were granted to the client driver	Pointer to the client driver's device object	A Client driver tried to open an invalid number of static streams. The number of streams cannot be 0 and cannot be greater than the value returned to the client driver in the query USB capability call.
0x803	Pointer to the Open Static Streams IRP	Pointer to the Open Static Streams URB	Pointer to the client driver's device object	A client driver attempted to open static streams for an endpoint that already had static streams open. Before opening static streams, the client driver must close the previously opened static streams.
0x804	The leaked handle context. Run !usbanalyze -v to get information about the leaked handle and URBs. You must enable Driver Verifier for the client driver.	Device object passed to USBD_CreateHandle .	Reserved	A client driver forgot to close a handle it created earlier using USBD_CreateHandle or forgot to free an URB it allocated.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x805	WDFREQUEST handle for the Close Static Streams URB	Pointer to the Close Static Streams URB	Pointer to the client driver's device object	A client driver sent a Close Static Streams URB in an invalid state (for example, after processing D0 Exit).
0x806	Pointer to the IRP	Pointer to the URB	Pointer to the client driver's device object	A client driver attempted to send a chained MDL before querying for chained MDL capability. A client driver cannot send a chained MDL until after it successfully queries for the chained MDL capability. For more information, see Remarks.
0x807	Pointer to the chained MDL	Pointer to the URB	Pointer to the client driver's device object if available	A client driver sent an URB to the core stack with a transfer buffer length longer than the byte count (returned by MmGetMdlByteCount) of the MDL passed in. For more information, see Remarks.
0x1001	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The xHCI controller asserted the HSE bit, which indicates a host system error.
0x1002	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The xHCI controller asserted the HCE bit, which indicates a host controller error.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1003	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The xHCI stop endpoint command returned an unhandled completion code.
0x1004	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The xHCI endpoint state received a context state error after an xHCI endpoint stop command was issued.
0x1005	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Set dequeue pointer failed during an attempt to clear stall on control endpoint.
0x1006	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Reset EP failed during an attempt to clear stall on control endpoint.
0x1007	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The reset of the xHCI controller failed during reset recovery.
0x1008	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The restart of the xHCI controller failed during reset recovery.
0x1009	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	An xHCI controller command failed to complete after the command timeout abort.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x100A	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Set dequeue pointer failed during an attempt to set the dequeue pointer after endpoint stop completion.
0x100B	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The stop of the xHCI controller failed during reset recovery.
0x100C	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The firmware in the xHCI controller is not supported. The xHCI driver will not load on this controller unless the firmware is updated.
0x100D	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The controller was detected to be physically removed.
0x100E	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The driver detect an error on a stream enabled endpoint.
0x100F	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The firmware in the xHCI controller is outdated. The xHCI driver will continue working with this controller but may run into some issues. A firmware update is recommended.
0x1010	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	A transfer event TRB completed with an unhandled completion code.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1011	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The controller reported that the event ring became full. The controller is also known to drop events when this happens.
0x1012	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The controller completed a command out of order.
0x1013	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	After command abort completion, the command ring dequeue pointer reported by the controller is incorrect.
0x1014	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	After enable slot completion, controller gave us a bad slot id.
0x1015	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Controller failed a SetAddress command with BSR1. That is unexpected.
0x1016	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Controller failed to enable a slot during a usbdevice reset. This is unexpected.
0x1017	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Controller failed an endpoints configure command where we were deconfiguring the endpoints. That is unexpected.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x1018	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Controller failed a disable slot command. That is unexpected.
0x1019	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Controller failed a USB device reset command. That is unexpected.
0x101A	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	After endpoint reset, Set Dequeue Pointer command failed.
0x101B	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The xHCI reset endpoint command returned an unhandled completion code.
0x101C	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The D0Entry for xHCI failed.
0x101D	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Temporarily dropping and adding a stream endpoint (as two commands) failed, when using the Configure Endpoint command instead of Set Dequeue Pointer during request cancellation.
0x101E	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The controller indicated a transfer completion that was not pending on the controller. EventData == 1 (dereferencing the Transfer Event TRB's pointer would have caused a bugcheck)

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x101F	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The controller indicated a transfer completion that was not pending on the controller. EventData == 0 (logical address in transfer event TRB not matched)
0x1020	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	The controller indicated a transfer completion that was not pending on the controller. EventData == 0 (logical address in transfer event TRB not matched) The Transfer Event TRB may be redundant (points somewhere near a recently completed request).
0x1021	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Temporarily dropping and adding a stream endpoint (as two commands) failed, when using the Configure Endpoint command as part of resetting an endpoint that was not Halted.
0x1022	XHCI_LIVEDUMP_CONTEXT	Reserved	Reserved	Dropping and adding the same endpoint (as one command) failed.
0x3000	USBHUB3_LIVEDUMP_CONTEXT	Reserved	Reserved	A misbehaving hub was successfully reset by the hub driver.

PARAMETER 1	PARAMETER 2	PARAMETER 3	PARAMETER 4	CAUSE OF ERROR
0x3001	USBHUB3_LIVED UMP_CONTEXT	Reserved	Reserved	A misbehaving hub failed to be reset successfully by the hub driver.
0x3002	USBHUB3_LIVED UMP_CONTEXT	Reserved	Reserved	A non-function SuperSpeed hub was disabled by the hub driver.
0x3003	USBHUB3_LIVED UMP_CONTEXT	Reserved	Reserved	A USB device failed enumeration.

Remarks

To query for a USB capability, the client driver must call [WdfUsbTargetDeviceQueryUsbCapability](#) or [USBD_QueryUsbCapability](#)

To send a chained **MDL**, the client driver must call [USBD_QueryUsbCapability](#) and use **URB_FUNCTION_BULK_OR_INTERRUPT_TRANSFER_USING_CHAINED_MDL** or **URB_FUNCTION_ISOCH_TRANSFER_USING_CHAINED_MDL**.

Bug Check 0x145: SECURE_BOOT_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The SECURE_BOOT_VIOLATION bug check has a value of 0x00000145. This indicates that the secure Boot policy enforcement could not be started due to an invalid policy or a required operation not being completed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SECURE_BOOT_VIOLATION Parameters

PARAMETER	DESCRIPTION
1	The status code of the failure.
2	Address of the Secure Boot policy.
3	Size of the Secure Boot policy.
4	Reserved

Bug Check 0x147: ABNORMAL_RESET_DETECTED

5/26/2017 • 1 min to read • [Edit Online](#)

The ABNORMAL_RESET_DETECTED bug check has a value of 0x00000147. This indicates that Windows underwent an abnormal reset. No context or exception records were saved, and bugcheck callbacks were not called.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ABNORMAL_RESET_DETECTED Parameters

None

Bug Check 0x14B: SOC_SUBSYSTEM_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The SOC_SUBSYSTEM_FAILURE bug check has a value of 0x0000014B. This indicates that an unrecoverable error was encountered in a System on a Chip (SoC) subsystem.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x14B SOC_SUBSYSTEM_FAILURE Parameters

PARAMETER	DESCRIPTION
1	Address of an SOC_SUBSYSTEM_FAILURE_DETAILS structure.
2	Reserved.
3	Reserved.
4	Optional. Address of a vendor-supplied data block.

Resolution

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in determining the root cause.

```
2: kd> !analyze -v
*****
*                               *
*           Bugcheck Analysis  *
*                               *
*****
SOC_SUBSYSTEM_FAILURE (14b)
A SOC subsystem has experienced an unrecoverable critical fault.
Arguments:
Arg1: 9aa8d630, nt!SOC_SUBSYSTEM_FAILURE_DETAILS
Arg2: 00000000, Reserved
Arg3: 00000000, Reserved
Arg4: a126c000, (Optional) address to vendor supplied general purpose data block.
```

Use the provided nt!SOC_SUBSYSTEM_FAILURE_DETAILS structure to dump the failure data using the dt command and the address provided by Arg1.

```
2: kd> dt nt!SOC_SUBSYSTEM_FAILURE_DETAILS 9aa8d630
+0x000 SubsysType      : 1 ( SOC_SUBSYS_AUDIO_DSP )
+0x008 FirmwareVersion : 0
+0x010 HardwareVersion : 0
+0x018 UnifiedFailureRegionSize : 0x24
+0x01c UnifiedFailureRegion : [1]  "F"
```

Work with SoC vendor to further parse the data, including the optional vendor supplied general purpose data block.

You may want to examine the stack trace using the **k, kb, kc, kd, kp, kP, kv (Display Stack Backtrace)** command. You can specify the processor number to examine the stacks on all processors.

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- For additional general troubleshooting information, see [Blue Screen Data](#).

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012

Bug Check 0x149: REFS_FILE_SYSTEM

5/26/2017 • 1 min to read • [Edit Online](#)

The REFS_FILE_SYSTEM bug check has a value of 0x00000149. This indicates that a file system error has occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

REFS_FILE_SYSTEM Parameters

PARAMETER	DESCRIPTION
1	__LINE__
2	ExceptionRecord
3	ContextRecord
4	ExceptionRecord->ExceptionAddress

PARAMETER	DESCRIPTION
1	Message
2	Reserved
3	Reserved
4	Reserved

Resolution

If you see RefsExceptionFilter on the stack then the 2nd and 3rd parameters are the exception record and context record. Do a .exr on the 2nd parameter to view the exception information. Do a .cxr on the 3rd parameter and then kb to obtain a more informative stack trace.

Bug Check 0x14A: KERNEL_WMI_INTERNAL

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_WMI_INTERNAL bug check has a value of 0x0000014A. This indicates that the internal kernel WMI subsystem has encountered a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_WMI_INTERNAL Parameters

PARAMETER	DESCRIPTION
1	0 : A kernel WMI entry reference count was incremented from 0. Parameter 2: Pointer to the kernel WMI entry. 1 : A kernel WMI datasource was removed prematurely. Parameter 2: Pointer to the kernel WMI datasource.
2	See parameter 1
3	Reserved
4	Reserved

Bug Check 0x14C: FATAL_ABNORMAL_RESET_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The FATAL_ABNORMAL_RESET_ERROR bug check has a value of 0x0000014C. This indicates that an unrecoverable system error occurred or the system has abnormally reset.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

FATAL_ABNORMAL_RESET_ERROR Parameters

None

Cause

The system encountered an unexpected error and restarted. Issues that may cause this error include: hardware watchdog timer in application or auxiliary processors indicating a system hang, user-initiated key sequence because of a hang, a brownout, or failures in the default bugcheck path. The cache may not be flushed and the resulting full memory dump may not contain the current thread context.

Secondary data of tag {E1D08891-D5A3-45F9-B811-AD711DFB2607} contains additional "Blackbox" data. Use [.enumtag \(Enumerate Secondary Callback Data\)](#) to view the data.

Bug Check 0x14D: EXCEPTION_SCOPE_INVALID

5/26/2017 • 1 min to read • [Edit Online](#)

The EXCEPTION_SCOPE_INVALID bug check has a value of 0x0000014D. This indicates that an internal inconsistency in exception dispatching has been detected.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

EXCEPTION_SCOPE_INVALID Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x14E: SOC_CRITICAL_DEVICE_REMOVED

5/26/2017 • 1 min to read • [Edit Online](#)

The SOC_CRITICAL_DEVICE_REMOVED bug check has a value of 0x0000014E. This indicates that a critical SOC device has been unexpectedly removed or failed.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SOC_CRITICAL_DEVICE_REMOVED Parameters

PARAMETER	DESCRIPTION
1	When available, indicates the ID of the device which was removed (4 character packed code)
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x14F: PDC_WATCHDOG_TIMEOUT

5/26/2017 • 1 min to read • [Edit Online](#)

The PDC_WATCHDOG_TIMEOUT bug check has a value of 0x0000014F. This indicates that a system component failed to respond within the allocated time period, preventing the system from exiting connected standby.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PDC_WATCHDOG_TIMEOUT Parameters

PARAMETER	DESCRIPTION
1	Client ID of the hung component.
2	Client type of the hung component. 0x1 : A notification client failed to respond. Parameter 3: Pointer to the notification client (PDC_NOTIFICATION_CLIENT). Parameter 4: Pointer to a pdc!PDC_14F_TRIAGE structure. 0x2 : A resiliency client failed to respond. Parameter 3: Pointer to the resiliency client (PDC_RESILIENCY_CLIENT). Parameter 4: Pointer to a pdc!PDC_14F_TRIAGE structure. 0x3 : An activator client held a reference for too long. Parameter 3: Pointer to the activation client (pdc!PDC_ACTIVATOR_CLIENT). Parameter 4: Pointer to a pdc!PDC_14F_TRIAGE structure. 0x100 : Win32k did not complete a monitor-on request in a timely manner. Parameter 3: The most recent POWER_MONITOR_REQUEST_REASON value for this request. Parameter 4: A value indicating the internal path taken to initiate the request.
3	See parameter 2
4	See parameter 2

Bug Check 0x150: TCPIP_AOAC_NIC_ACTIVE_REFERENCE_LEAK

5/26/2017 • 1 min to read • [Edit Online](#)

The TCPIP_AOAC_NIC_ACTIVE_REFERENCE_LEAK bug check has a value of 0x00000150. This indicates that the NIC active reference should have been released when the send queue was fully drained.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

TCPIP_AOAC_NIC_ACTIVE_REFERENCE_LEAK Parameters

None

Bug Check 0x151: UNSUPPORTED_INSTRUCTION_MODE

5/26/2017 • 1 min to read • [Edit Online](#)

The UNSUPPORTED_INSTRUCTION_MODE bug check has a value of 0x00000151. This indicates that an attempt was made to execute code using an unsupported processor instruction mode (for example, executing classic ARM instructions instead of ThumbV2 instructions). This is not permitted.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UNSUPPORTED_INSTRUCTION_MODE Parameters

PARAMETER	DESCRIPTION
1	Program counter when the problem was detected.
2	Trap Frame
3	Reserved
4	Reserved

Bug Check 0x152: INVALID_PUSH_LOCK_FLAGS

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_PUSH_LOCK_FLAGS bug check has a value of 0x00000152. This indicates that the flags supplied to one of push lock APIs were invalid.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_PUSH_LOCK_FLAGS Parameters

PARAMETER	DESCRIPTION
1	The invalid flags supplied by the caller
2	The address of the push lock
3	Reserved
4	Reserved

Bug Check 0x153: KERNEL_LOCK_ENTRY_LEAKED_ON_THREAD_TERMINATION

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_LOCK_ENTRY_LEAKED_ON_THREAD_TERMINATION bug check has a value of 0x00000153. This indicates that a thread was terminated before it had freed all its AutoBoost lock entries.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_LOCK_ENTRY_LEAKED_ON_THREAD_TERMINATION Parameters

PARAMETER	DESCRIPTION
1	The address of the thread
2	The address of the entry that was not freed
3	A status code indicating the state of the entry 0x1 : Lock pointer was not NULL 0x2 : Thread pointer reserved bits were set 0x3 : Thread pointer was corrupted 0x4 : The entry had residual IO or CPU boosts left
4	Reserved

Cause

This is typically caused when a thread never released a lock it previously acquired (e.g. by relying on another thread to release it), or if the thread did not supply a consistent set of flags to lock package APIs.

Bug Check 0x154: UNEXPECTED_STORE_EXCEPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The UNEXPECTED_STORE_EXCEPTION bug check has a value of 0x00000154. This indicates that the store component caught an unexpected exception.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UNEXPECTED_STORE_EXCEPTION Parameters

PARAMETER	DESCRIPTION
1	Pointer to the store context or data manager
2	Exception information
3	Reserved
4	Reserved

Bug Check 0x155: OS_DATA_TAMPERING

5/26/2017 • 1 min to read • [Edit Online](#)

The OS_DATA_TAMPERING bug check has a value of 0x00000155.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

OS_DATA_TAMPERING Parameters

None

Bug Check 0x156: WINSOCK_DETECTED_HUNG_CLOSESOCKET_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The WINSOCK_DETECTED_HUNG_CLOSESOCKET_LIVEDUMP bug check has a value of 0x00000156. This indicates that Winsock detected a hung transport endpoint close request.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WINSOCK_DETECTED_HUNG_CLOSESOCKET_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	AFD endpoint pointer (!afdkd.endp <ptr>)
2	Transport endpoint type 0x1 : UDP datagram 0x2 : RAW datagram 0x3 : TCP listener 0x4 : TCP endpoint
3	Number of buffered send bytes for datagram endpoints
4	afd!NETIO_SUPER_TRIAGE_BLOCK

Cause

While processing a closesocket request, Winsock detected a hung transport endpoint close request. The system generated a live dump for analysis, then the closesocket request was completed without waiting for the completion of hung transport endpoint close request.

Bug Check 0x157: KERNEL_THREAD_PRIORITY_FLOOR_VIOLATION

5/26/2017 • 1 min to read • [Edit Online](#)

The ATTEMPTED_SWITCH_FROM_DPC bug check has a value of 0x00000157. This indicates that an illegal operation was attempted on the priority floor of a particular thread.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_THREAD_PRIORITY_FLOOR_VIOLATION Parameters

PARAMETER	DESCRIPTION
1	The address of the thread
2	The target priority value
3	A status code indicating the nature of the violation 0x1 : The priority counter for the target priority over-flowed 0x2 : The priority counter for the target priority under-flowed 0x3 : The target priority value was illegal
4	Reserved

Bug Check 0x158: ILLEGAL_IOMMU_PAGE_FAULT

5/26/2017 • 1 min to read • [Edit Online](#)

The ILLEGAL_IOMMU_PAGE_FAULT bug check has a value of 0x00000158. This indicates that the IOMMU has delivered a page fault packet for an invalid ASID. This is not safe since the ASID may have already been reused.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ILLEGAL_IOMMU_PAGE_FAULT Parameters

PARAMETER	DESCRIPTION
1	The invalid ASID.
2	The number of ASIDs currently in use.
3	The process using this ASID.
4	The ASID's reference count.

Bug Check 0x159: HAL_ILLEGAL_IOMMU_PAGE_FAULT

5/26/2017 • 1 min to read • [Edit Online](#)

The HAL_ILLEGAL_IOMMU_PAGE_FAULT bug check has a value of 0x00000159. This indicates that the IOMMU has delivered a page fault against an ASID that was in the process of being freed. The driver was responsible for completing any inflight requests before this point in time and this bugcheck indicates a driver in the system did not do so.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

HAL_ILLEGAL_IOMMU_PAGE_FAULT Parameters

PARAMETER	DESCRIPTION
1	IOMMU Vendor disambiguation
2	Pointer to fault packet
3	Vendor specific fault packet data
4	Vendor specific fault packet data

PARAMETER	DESCRIPTION
1	IOMMU Vendor disambiguation = 0x3xx.
2	Status
3	PASID
4	DirectoryBase

Bug Check 0x15A: SDBUS_INTERNAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The SDBUS_INTERNAL_ERROR bug check has a value of 0x0000015A. This indicates that an unrecoverable hardware failure has occurred on an SD-attached device.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SDBUS_INTERNAL_ERROR Parameters

PARAMETER	DESCRIPTION
1	Pointer to the internal SD work packet that caused the failure
2	Pointer to the controller socket information
3	Pointer to the SD request packet sent down to the bus driver
4	Reserved

Bug Check 0x15B:

WORKER_THREAD_RETURNED_WITH_SYSTEM_PAGE_PRIORITY_ACTIVE

5/26/2017 • 1 min to read • [Edit Online](#)

The WORKER_THREAD_RETURNED_WITH_SYSTEM_PAGE_PRIORITY_ACTIVE bug check has a value of 0x0000015B. This indicates that a worker thread's system page priority was leaked by the called worker routine.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WORKER_THREAD_RETURNED_WITH_SYSTEM_PAGE_PRIORITY_ACTIVE Parameters

PARAMETER	DESCRIPTION
1	Address of worker routine (do <code>!n</code> on this address to find the offending driver)
2	Current system page priority value
3	WorkItem parameter
4	WorkItem address

Bug Check 0x15C: PDC_WATCHDOG_TIMEOUT_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The PDC_WATCHDOG_TIMEOUT_LIVEDUMP bug check has a value of 0x0000015C. This indicates that a system component failed to respond within the allocated time period, preventing the system from entering or exiting connected standby.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PDC_WATCHDOG_TIMEOUT_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	Client ID of the hung component.
2	Client type of the hung component. 0x1 : A notification client failed to respond. 3 - Pointer to the notification client (pdc!_PDC_NOTIFICATION_CLIENT). 4 - Pointer to a pdc!PDC_14F_TRIAGE structure. 0x2 : A resiliency client failed to respond. 3 - Pointer to the resiliency client (pdc!_PDC_RESILIENCY_CLIENT). 4 - Pointer to a pdc!PDC_14F_TRIAGE structure. 0x3 : An activator client held a reference for too long 3 - Pointer to the activation client (pdc!_PDC_ACTIVATOR_CLIENT). 4 - Pointer to a pdc!PDC_14F_TRIAGE structure.
3	See parameter 2
4	See parameter 2

Bug Check 0x15D: SOC_SUBSYSTEM_FAILURE_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The SOC_SUBSYSTEM_FAILURE_LIVEDUMP bug code has a value of 0x0000015D. This indicates that a System on a Chip (SoC) subsystem has experienced a critical fault and has captured a live kernel dump. The SoC subsystem does not generate a bug check in this situation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x14B SOC_SUBSYSTEM_FAILURE Parameters

PARAMETER	DESCRIPTION
1	Address of an SOC_SUBSYSTEM_FAILURE_DETAILS structure.
2	Reserved.
3	Reserved.
4	Optional. Address of a vendor-supplied data block.

Resolution

The [!analyze](#) debug extension displays information about the bug check and can be very helpful in determining the root cause.

Use the provided nt!SOC_SUBSYSTEM_FAILURE_DETAILS structure to dump the failure data using the dt command and the address provided by Arg1.

```
2: kd> dt nt!SOC_SUBSYSTEM_FAILURE_DETAILS 9aa8d630
+0x000 SubsysType      : 1 ( SOC_SUBSYS_AUDIO_DSP )
+0x008 FirmwareVersion : 0
+0x010 HardwareVersion : 0
+0x018 UnifiedFailureRegionSize : 0x24
+0x01c UnifiedFailureRegion : [1]  "F"
```

Work with SoC vendor to further parse the data, including the optional vendor supplied general purpose data block.

You may want to examine the stack trace using the [k, kb, kc, kd, kp, kP, kv \(Display Stack Backtrace\)](#) command. You can specify the processor number to examine the stacks on all processors.

You can also set a breakpoint in the code leading up to this stop code and attempt to single step forward into the faulting code.

For more information see the following topics:

[Crash dump analysis using the Windows debuggers \(WinDbg\)](#)

If you are not equipped to use the Windows debugger to work on this problem, you can use some basic troubleshooting techniques.

- Check the System Log in Event Viewer for additional error messages that might help identify the device or driver that is causing this bug check.
- If a driver is identified in the bug check message, disable the driver or check with the manufacturer for driver updates.
- You can try running the hardware diagnostics supplied by the system manufacturer.
- For additional general troubleshooting information, see [Blue Screen Data](#).

Requirements

Minimum supported client	Windows 8
Minimum supported server	Windows Server 2012

Bug Check 0x15E: BUGCODE_NDIS_DRIVER_LIVE_DUMP

5/26/2017 • 3 min to read • [Edit Online](#)

The BUGCODE_NDIS_DRIVER_LIVE_DUMP bug code has a value of 0x0000015E. This bug code indicates that NDIS has captured a live kernel dump. NDIS does not generate a bug check in this situation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BUGCODE_NDIS_DRIVER Parameters

Parameter 1 indicates the type of violation. The meaning of the other parameters depends on the value of Parameter 1. If a Parameter's value is "0," that means it is not used.

PARAMETER 1	PARAMETER 1 VALUE AND CAUSE OF ERROR	PARAMETER 2	PARAMETER 3	PARAMETER 4
0x01	<p>NDIS_BUGCHECK _MINIPORT_FATA L_ERROR</p> <p>A miniport driver has encountered a fatal error and requested re-enumeration.</p>	<p>The address of the miniport block. Run !ndiskd.minidriver with this address for more information.</p>	<p>The address of the miniport's Physical Device Object (PDO)</p>	<p>The fatal error that caused this live dump to be taken. Possible values:</p> <ol style="list-style-type: none">1. 70: Caused by user mode2. 71: Caused by NdisMRemoveMiniport3. 72: Caused by NdisMInitializeDeviceInstanceEx failing4. 73: Caused by MiniportRestart failing5. 74: Caused by failing a OID_PNP_SET_POWER (D0) request6. 75: Caused by failing a OID_PNP_SET_POWER (Dx) request
0x25	<p>NDIS_BUGCHECK _WATCHDOG</p> <p>An attempt to manage the network stack has taken too long. When NDIS calls</p>	<p>The operation that took too long. Possible values:</p> <ul style="list-style-type: none">• 0x01 : NDIS_BUG CHECK_W	<p>Cast to ndis!NDIS_WATCHDOG_TRIAGE_B LOCK. Useful fields:</p> <ul style="list-style-type: none">• StartTime shows what	<p>The value of Parameter 4 depends on the value of Parameter 2. Each number in this list corresponds to the same number</p>

PARAMETER 1	out into other PARAMETER 1 VALUE AND CAUSE OF ERROR starts a watchdog	ATCHDOG PROTOC OL_PAUSE	time the operation started, in PARAMETER 3	in Parameter 2. PARAMETER 4
	<p>timer to ensure the call completes promptly. If the call takes too long, NDIS injects a bugcheck.</p> <p>This can be caused by a simple deadlock. Look with "!stacks 2 ndis" or similar to see if any threads look suspicious. Pay special attention to the PrimaryThread from the NDIS_WATCHDOG_TRIAGE_BLOCK.</p> <p>This can be caused by lost NBLs, in which case !ndiskd.pending_nbls may help. Check for OIDs that are stuck using !ndiskd.oid.</p>	<p>There was a timeout while pausing a protocol driver.</p> <ul style="list-style-type: none"> 0x02 : NDIS_BUG_CHECK_W_ATCHDOG_PROTOC_OL_NETPN_PEVENT 0x03 : NDIS_BUG_CHECK_W_ATCHDOG_PROTOC_OL_STATUS_INDICATION 0x04 : NDIS_BUG_CHECK_W_ATCHDOG_PROTOC_OL_UNBIND 0x11 : NDIS_BUG_CHECK_W 	<p>100ns units, as returned by KeQueryInterruptTime.</p> <ul style="list-style-type: none"> • TimeoutMillis econds shows how long NDIS waited, at a minimum, before triggering this bugcheck. • TargetObject is a handle to the protocol, filter module, or miniport adapter that NDIS is waiting on. Run !ndiskd.proto_col, !ndiskd.filter, or !ndiskd.netadapter with this handle for more information. • PrimaryThread ad is the thread on which NDIS initiated the operation. Usually, this is the first place to look, although the thread may have gone elsewhere if the operation is being handled asynchronously. 	<ul style="list-style-type: none"> • 0x02 : The NDIS_STATUS code of the stuck event. For more information about these codes, see NET_PNP_EVE_NT.. • 0x03 : The NDIS_STATUS code of the stuck indication. Use !ndiskd.help to decode it. • 0x04 : 0 • 0x11 : 0 • 0x12 : The NDIS_STATUS code of the stuck event. For possible values, see the previous list of values for item 2 in this list. • 0x13 : The NDIS_STATUS code of the stuck indication. Use !ndiskd.help to decode it. • 0x14 : 0 • 0x21 : 0 • 0x22 : 0 • 0x23 : The OID code of the stuck request. Use !ndiskd.help to decode it. • 0x24 : The OID code of the stuck request. Use !ndiskd.help to decode it. • 0x25 : 0 • 0x26 : 0

PARAMETER 1	PARAMETER 1 VALUE AND CAUSE OF ERROR	ATCHDOG _FILTER_P AUSE	PARAMETER 3	PARAMETER 4
		<p>There was a timeout while pausing a filter driver.</p> <ul style="list-style-type: none"> • 0x12 : NDIS_BUG CHECK_W ATCHDOG _FILTER_N ETPNPEVE NT • There was a timeout while delivering a NET_PNP_ EVENT_N OTIFICATI ON to a filter driver. • 0x13 : NDIS_BUG CHECK_W ATCHDOG _FILTER_ST ATUS_IND ICATION • There was a timeout while delivering a status indication to a filter driver. • 0x14 : NDIS_BUG CHECK_W ATCHDOG _FILTER_D ETACH • There was a timeout while detaching a filter driver. • 0x21 : NDIS_BUG CHECK_W ATCHDOG _MINIPOR T_PAUSE

		<p>IDLE</p> <p>There was a timeout while canceling an idle request on a miniport adapter.</p>		
0x30	<p>NDIS_BUGCHECK_STUCK_NBL</p> <p>A miniport driver has not returned a NBL back to the stack for some time.</p>	<p>The address of the miniport block. Run !ndiskd.minidriver with this address for more information.</p>	0	0

Cause

Parameter 1 indicates the specific cause of the BUGCODE_NDIS_DRIVER_LIVE_DUMP bugcheck.

Remarks

NDIS has detected and recovered from a serious problem in another network driver. Although the system was not halted, this problem may later cause connectivity problems or a fatal bugcheck.

This bug code occurs only in Windows 8.1 and later versions of Windows.

Bug Check 0x15F: CONNECTED_STANDBY_WATCHDOG_TIMEOUT_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The CONNECTED_STANDBY_WATCHDOG_TIMEOUT_LIVEDUMP bug check has a value of 0x0000015F. This indicates that a connected standby watchdog timeout has occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CONNECTED_STANDBY_WATCHDOG_TIMEOUT_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	<p>CS watchdog subcode</p> <p>0x1 : DRIPS watchdog timeout. The system has been in the resiliency phase of connected standby with no activators active and no device constraints unsatisfied for too long without entering DRIPS (deepest runtime idle platform state).</p> <p>2 - A pointer to additional information (nt!POP_DRIPS_WATCHDOG_METRICS)</p> <p>3 - Non-DRIPS duration in milliseconds</p> <p>4 - Reserved</p> <p>0x2 : DRIPS watchdog device constraint timeout. The system has been in the resiliency phase of connected standby for too long without entering DRIPS (deepest runtime idle platform state) due to an unsatisfied device constraint with no activators active.</p> <p>2 - nt!TRIAGE_POP_FX_DEVICE Device</p> <p>3 - Component index</p> <p>4 - Reserved</p> <p>0x3 : DRIPS watchdog preveto timeout. The system has been in the resiliency phase of connected standby for too long without entering DRIPS (deepest runtime idle platform state) due to an active PEP pre-veto with no unsatisfied device constraint and with no activators active.</p> <p>2 - Veto code</p> <p>3 - A pointer to the veto name string (PWSTR)</p> <p>4 - A pointer to the PEP PPM callback</p> <p>0x4 : Deep Sleep Watchdog</p> <p>2 - Metrics</p> <p>3 - NonDeepSleepDurationMs</p> <p>4 - Reserved</p> <p>0x5 : Deep Sleep Power Setting Watchdog</p> <p>2 - Metrics</p> <p>3 - NonDeepSleepDurationMs</p> <p>4 - Reserved</p>
2	See parameter 1

PARAMETER	DESCRIPTION
3	See parameter 1
4	See parameter 1

Cause

This machine is exhibiting behavior that reduces screen-off battery life. Typically this is caused by CPU activity, device activity, or devices being in an insufficient idle state.

Bug Check 0x160: WIN32K_ATOMIC_CHECK_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The WIN32K_ATOMIC_CHECK_FAILURE bug check has a value of 0x00000160. This indicates that a Win32k function has violated an ATOMICCHECK.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WIN32K_ATOMIC_CHECK_FAILURE Parameters

PARAMETER	DESCRIPTION
1	Count of functions on the stack currently inside of an ATOMIC operation
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x161: LIVE_SYSTEM_DUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The LIVE_SYSTEM_DUMP bug check has a value of 0x00000161. This indicates that the system administrator requested the collection of a live system memory dump.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

LIVE_SYSTEM_DUMP Parameters

None

Bug Check 0x162: KERNEL_AUTO_BOOST_INVALID_LOCK_RELEASE

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_AUTO_BOOST_INVALID_LOCK_RELEASE bug check has a value of 0x00000162. This indicates that a lock tracked by AutoBoost was released by a thread that did not own the lock.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_AUTO_BOOST_INVALID_LOCK_RELEASE Parameters

PARAMETER	DESCRIPTION
1	The address of the thread
2	The lock address
3	The session ID of the thread
4	Reserved

Cause

This is typically caused when some thread releases a lock on behalf of another thread (which is not legal with AutoBoost tracking enabled) or when some thread tries to release a lock it no longer owns.

Bug Check 0x163: WORKER_THREAD_TEST_CONDITION

5/26/2017 • 1 min to read • [Edit Online](#)

The WORKER_THREAD_TEST_CONDITION bug check has a value of 0x00000163. This indicates that a test for kernel worker threads raised a failure.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WORKER_THREAD_TEST_CONDITION Parameters

PARAMETER	DESCRIPTION
1	Active test flags
2	Flag corresponding to the test that triggered the failure
3	Reserved
4	Reserved

Bug Check 0x164: WIN32K_CRITICAL_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The WIN32K_CRITICAL_FAILURE bug check has a value of 0x00000164. This indicates that Win32k has encountered a critical failure.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WIN32K CRITICAL FAILURE Parameters

PARAMETER	DESCRIPTION
1	<p>1 - Type of the failure.</p> <p>0x1 : REGION_VALIDATION_FAILURE- Region is out of surface bounds.</p> <p>2 - Pointer to DC</p> <p>3 - Pointer to SURFACE</p> <p>4 - Pointer to REGION</p> <p>0x2 : OPERATOR_NEW_USED - Operator "new" is used to allocate memory.</p> <p>2 - Reserved</p> <p>3 - Reserved</p> <p>4 - Reserved</p> <p>0x3 : CRITICAL_APISET_EXTENSIONS_MISSING - Critical extension APISET API is missing.</p> <p>2 - wchar_t* to the name of the missing function</p> <p>3 - Reserved</p> <p>4 - Reserved</p> <p>0x4 : GDI_SPRITE_SURFACE_INVALID_DELETE - GDI sprite's shape is being deleted without deleting the sprite.</p> <p>2 - Handle to the SURFACE</p> <p>3 - Reference count to the SURFACE</p> <p>4 - PID of the SURFACE owner</p> <p>0x5 : POINTER_DEVICE_EXCLUSIVE_OPEN_FAILED - Failed to open Pointer device.</p> <p>2 - UNICODE_STRING of the device</p> <p>3 - Reserved</p> <p>4 - Reserved</p> <p>0x8 : PUBLIC_DC_INVALID_PRIVATE_MEMBER - A public DC has a pointer to an object owned by a specific process.</p> <p>2 - Pointer to DC</p> <p>3 - Process id that owns the object</p> <p>4 - Reserved</p>

PARAMETER	0xA : TTFD_INVOKE_ILLEGAL_ID - Invalid function table index DESCRIPTION is being used in TTFD.
2	2 - Reserved
3	3 - Reserved
4	4 - Reserved
	0xB : OTFD_INVOKE_ILLEGAL_ID - Invalid function table index is being used in ATMFD.
2	2 - Reserved
3	3 - Reserved
4	4 - Reserved
	0xC : GFPE_INVOKE_ILLEGAL_ID - Invalid function table index is being used in a PALETTE.
2	2 - Pointer to the PALETTE
3	3 - The invalid index
4	4 - Maximum valid index + 1
	0x10 : USER_SAS_REGISTRATION_FAILED - SAS key registration has failed.
2	2 - vkey
3	3 - modifiers
4	4 - flags
2	See parameter 1
3	See parameter 1
4	See parameter 1

Bug Check 0x16C: INVALID_RUNDOWN_PROTECTION_FLAGS

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_RUNDOWN_PROTECTION_FLAGS bug check has a value of 0x0000016C. This indicates that the flags supplied to one of the rundown protection APIs were invalid.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_RUNDOWN_PROTECTION_FLAGS Parameters

PARAMETER	DESCRIPTION
1	The invalid flags supplied by the caller
2	The address of the rundown ref
3	Reserved
4	Reserved

Bug Check 0x16D: INVALID_SLOT_ALLOCATOR_FLAGS

5/26/2017 • 1 min to read • [Edit Online](#)

The INVALID_SLOT_ALLOCATOR_FLAGS bug check has a value of 0x0000016D. This indicates that the flags supplied to one of the slot allocator APIs were invalid.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

INVALID_SLOT_ALLOCATOR_FLAGS Parameters

PARAMETER	DESCRIPTION
1	The invalid flags supplied by the caller
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x16E: ERESOURCE_INVALID_RELEASE

5/26/2017 • 1 min to read • [Edit Online](#)

The ERESOURCE_INVALID_RELEASE bug check has a value of 0x0000016E. This indicates that the target thread pointer supplied to ExReleaseResourceForThreadLite was invalid.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ERESOURCE_INVALID_RELEASE Parameters

PARAMETER	DESCRIPTION
1	The resource being released
2	The current thread
3	The incorrect target thread that was passed in
4	Reserved

Cause

This bugcheck will hit if a call to ExSetOwnerPointerEx was skipped by the API client (if a cross-thread release was intended) or if the caller accidentally passed in a value other than supplied by ExGetCurrentResourceThread.

Bug Check 0x175: PREVIOUS_FATAL_ABNORMAL_RESET_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The PREVIOUS_FATAL_ABNORMAL_RESET_ERROR bug check has a value of 0x00000175. This indicates that an unrecoverable system error occurred or the system has abnormally reset on Windows phone devices. The system generated a live dump to collect device crash data from the previous error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PREVIOUS_FATAL_ABNORMAL_RESET_ERROR Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	Reserved

Cause

The system on Windows Phone devices encountered an unexpected error and restarted. Issues that may cause this error include: hardware watchdog timer in application or auxiliary processors indicating a system hang, user-initiated key sequence because of a hang, etc.

Bug Check 0x178: ELAM_DRIVER_DETECTED_FATAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The ELAM_DRIVER_DETECTED_FATAL_ERROR bug check has a value of 0x00000178. This indicates that ELAM driver detected a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

ELAM_DRIVER_DETECTED_FATAL_ERROR Parameters

PARAMETER	DESCRIPTION
1	Type of the failure. 0x0 : TPM attestation could not be revoked 2 - Pointer to the BDCB_IMAGE_INFORMATION structure for the driver being inspected 3 - TBS_RESULT failure code 0x10000 : ELAM-vendor defined failure 2 - (Optional) ELAM vendor supplied value 3 - (Optional) ELAM vendor supplied value
2	See parameter 1
3	See parameter 1
4	(Optional) ELAM vendor supplied general purpose data block

Bug Check 0x187: VIDEO_DWMINIT_TIMEOUT_FALLBACK_BDD

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_DWMINIT_TIMEOUT_FALLBACK_BDD bug check has a value of 0x00000187. This indicates that video fell back to BDD rather than using the IHV driver. This always generates a live dump.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_DWMINIT_TIMEOUT_FALLBACK_BDD Parameters

PARAMETER	DESCRIPTION
1	Reason Code. 0x1 : DWM failed to initialize after retries, stopping display adapters and falling back to BDD
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x188: CLUSTER_CSVFS_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The CLUSTER_CSVFS_LIVEDUMP bug check has a value of 0x00000188. This indicates that CSVFS initiated this livedump to help debug an inconsistent state.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CLUSTER_CSVFS_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	Reason Code 0x1 : Cache purge on oplock downgrade to none has failed 2- address of CSVFS!_SCB 0x2 : Cache purge on oplock upgrade from none has failed 2- address of CSVFS!_SCB 0x3 : Cache purge on set purge failure mode 2- address of CSVFS!_SCB 0x4 : Cache flush on oplock downgrade to none failed 2- address of CSVFS!_SCB
2	See parameter 1
3	Reserved
4	Reserved

Cause

First parameter contains the reason code. When CSVFS detects that current state might cause data corruption or other sort of inconsistency, it would generate a live dump with this status code. Parameter 1 has code pointing to what scenario this live dump is created for. Other parameters should be interpreted in context of the reason code.

Bug Check 0x189: BAD_OBJECT_HEADER

5/26/2017 • 1 min to read • [Edit Online](#)

The BAD_OBJECT_HEADER bug check has a value of 0x00000189. This indicates that The OBJECT_HEADER has been corrupted.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BAD_OBJECT_HEADER Parameters

PARAMETER	DESCRIPTION
1	Pointer to bad OBJECT_HEADER
2	Pointer to the resulting OBJECT_TYPE based on the TypeIndex in the OBJECT_HEADER
3	Type of corruption. 0x0 : The type index is corrupt 0x1 : The object security descriptor is invalid
4	Reserved

Bug Check 0x18B: SECURE_KERNEL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The SECURE_KERNEL_ERROR bug check has a value of 0x0000018B. This indicates that the secure kernel has encountered a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SECURE_KERNEL_ERROR Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x190: WIN32K_CRITICAL_FAILURE_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The WIN32K_CRITICAL_FAILURE_LIVEDUMP bug check has a value of 0x00000190. This indicates that Win32k has encountered a critical failure. A live dump is captured to collect the debug information.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WIN32K_CRITICAL_FAILURE_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	Type of the failure 0x1 : REGION_VALIDATION_FAILURE - Region is out of surface bounds. 2- Pointer to DC 3- Pointer to SURFACE 4- Pointer to REGION 0x2 : OPERATOR_NEW_USED - Operator "new" is used to allocate memory. 2 - Reserved 3 - Reserved 4 - Reserved
2	See parameter 1
3	See parameter 1
4	See parameter 1

Bug Check 0x191: PF_DETECTED_CORRUPTION

5/26/2017 • 1 min to read • [Edit Online](#)

The PF_DETECTED_CORRUPTION bug check has a value of 0x00000191.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

PF_DETECTED_CORRUPTION Parameters

PARAMETER	DESCRIPTION
1	Reserved
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x192:

KERNEL_AUTO_BOOST_LOCK_ACQUISITION_WITH_RAISED_IRQL

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_AUTO_BOOST_LOCK_ACQUISITION_WITH_RAISED_IRQL bug check has a value of 0x00000192. This indicates that a lock tracked by AutoBoost was acquired while executing at DISPATCH_LEVEL or above.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_AUTO_BOOST_LOCK_ACQUISITION_WITH_RAISED_IRQL Parameters

PARAMETER	DESCRIPTION
1	The address of the thread
2	The lock address
3	The IRQL at which the lock was acquired
4	Reserved

Cause

The caller cannot be blocking on a lock above APC_LEVEL because the lock may be held exclusively by the interrupted thread, which would cause a deadlock.

Bug Check 0x193: VIDEO_DXGKRNLIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The VIDEO_DXGKRNLIVEDUMP bug check has a value of 0x00000193. This indicates a livedump triggered by dxgkrnl occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

VIDEO_DXGKRNLIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	Reason Code 0x100 Internal
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x195: SMB_SERVER_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The SMB_SERVER_LIVEDUMP bug check has a value of 0x00000195. This indicates the SMB server detected a problem and has captured a kernel dump to collect debug information.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

SMB_SERVER_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	0x1 : An I/O failed to complete in a reasonable amount of time. 2 - Pointer to the I/O's SRV2_WORK_ITEM
2	See parameter 1
3	Reserved
4	Reserved

Bug Check 0x196: LOADER_ROLLBACK_DETECTED

5/26/2017 • 1 min to read • [Edit Online](#)

The LOADER_ROLLBACK_DETECTED bug check has a value of 0x00000196. This indicates that the version of the OS loader does not match the operating system.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

LOADER_ROLLBACK_DETECTED Parameters

PARAMETER	DESCRIPTION
1	Loader security version
2	OS security version
3	Reserved
4	Reserved

Bug Check 0x197: WIN32K_SECURITY_FAILURE

5/26/2017 • 1 min to read • [Edit Online](#)

The WIN32K_SECURITY_FAILURE bug check has a value of 0x00000197. This indicates a security failure was detected in win32k.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WIN32K_SECURITY_FAILURE Parameters

PARAMETER	DESCRIPTION
1	Failure type 0x1 : An objects handle entry didn't point back to the object. 2 - Pointer to the object type 3 - Pointer to the object handle entry 4 - Expected object
2	See parameter 1
3	See parameter 1
4	See parameter 1

Bug Check 0x198: UFX_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The UFX_LIVEDUMP bug check has a value of 0x00000198. This indicates that a UFX live dump occurred.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

UFX_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	Failure type 0x1 : A class driver failed to activate the bus. 2 - Mask of enumerated child PDOs 3 - Mask of activated child PDOs 4 - Reserved
2	See parameter 1
3	See parameter 1
4	See parameter 1

Bug Check 0x199: KERNEL_STORAGE_SLOT_IN_USE

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_STORAGE_SLOT_IN_USE bug check has a value of 0x00000199. This indicates that the storage slot cannot be freed because there is an object using it.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

KERNEL_STORAGE_SLOT_IN_USE Parameters

PARAMETER	DESCRIPTION
1	The address of the storage array
2	Reserved
3	Reserved
4	Reserved

Bug Check 0x19A: WORKER_THREAD_RETURNED_WHILE_ATTACHED_TO_SILO

5/26/2017 • 1 min to read • [Edit Online](#)

The WORKER_THREAD_RETURNED_WHILE_ATTACHED_TO_SILO bug check has a value of 0x0000019A. This indicates that a worker thread attached to a silo and did not detach before returning.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WORKER_THREAD_RETURNED_WHILE_ATTACHED_TO_SILO Parameters

PARAMETER	DESCRIPTION
1	Address of worker routine
2	Workitem parameter
3	Workitem address
4	Reserved

Cause

To investigate use the [In \(List Nearest Symbols\)](#) command on parameter 1 to help identify the mis-behaving driver.

Bug Check 0x19B: TTM_FATAL_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The TTM_FATAL_ERROR bug check has a value of 0x0000019B. This indicates that the terminal topology manager experienced a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

TTM_FATAL_ERROR Parameters

PARAMETER	DESCRIPTION
1	Failure type 0x1 : An terminal object could not be generated. 2 - The NT status code of the failure 3 - Reserved 4 - Reserved
2	See parameter 1
3	See parameter 1
4	See parameter 1

Bug Check 0x19C: WIN32K_POWER_WATCHDOG_TIMEOUT

5/26/2017 • 1 min to read • [Edit Online](#)

The WIN32K_POWER_WATCHDOG_TIMEOUT bug check has a value of 0x0000019C. This indicates that Win32k did not turn the monitor on in a timely manner.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

WIN32K_POWER_WATCHDOG_TIMEOUT Parameters

PARAMETER	DESCRIPTION
1	Failure type (win32kbase!POWER_WATCHDOG_TYPE) 0x10 : The power request queue is not making progress 2 - Pointer to the thread processing power requests, if any 3 - Pointer to the win32k user lock 4 - Pointer to the power request (win32kbase!PPOWERREQUEST) being processed, if any 0x20 : Calling PO to set power state 2 - Pointer to the power request worker thread 3 - Reserved 4 - Reserved 0x30 : Calling GDI to power on 2 - Pointer to the power request worker thread 3 - Reserved 4 - Reserved 0x40 : Calling DWM to render 2 - Pointer to the power request worker thread 3 - Reserved 4 - Reserved 0x50 : Calling monitor driver to power on 2 - Pointer to the power request worker thread 3 - Reserved 4 - Reserved
2	See parameter 1
3	See parameter 1
4	See parameter 1

Bug Check 0x19D: CLUSTER_SVHDX_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The CLUSTER_SVHDX_LIVEDUMP bug check has a value of 0x0000019D. This indicates that SVHDX initiated this livedump to help debug an inconsistent state.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

CLUSTER_SVHDX_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	Reason code 0x1 : Mounting a Shared Virtual disk has failed 2 - Address of Svhdxfilt!_SVHDX_VIRTUALDISK_CONTEXT 3 - Address of nt!_FILE_OBJECT 4 - NTSTATUS
2	See parameter 1
3	See parameter 1
4	See parameter 1

Cause

When SVHDX detects that current state might cause some sort of inconsistency it will generate live dump with this status code. Parameter1 has code pointing to what scenario this live dump is created for. Other parameters should be interpreted in context of the reason code.

Bug Check 0x1C4: DRIVER_VERIFIER_DETECTED_VIOLATION_LIVEDUMP

5/31/2017 • 15 min to read • [Edit Online](#)

The DRIVER_VERIFIER_DETECTED_VIOLATION_LIVEDUMP bug check has a value of 0x0000001C4. This indicates that a device driver attempting to corrupt the system has been detected. This is because the driver was specified in the registry as being suspect (by the administrator) and the kernel has enabled substantial checking of this driver. For more information, see [Driver Verifier](#).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

DRIVER_VERIFIER_DETECTED_VIOLATION_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	<p>The subclass of driver violation.</p> <p>0x00081001: ID of the 'KsDeviceMutex' rule that was violated. Parameter 2 - A pointer to the string describing the violated rule condition. Parameter 3 - Address of internal rule state (second argument to !ruleinfo). Bug Check 0x1C5: IO_THREADPOOL_DEADLOCK_LIVEDUMP

5/26/2017 • 1 min to read • [Edit Online](#)

The IO_THREADPOOL_DEADLOCK_LIVEDUMP bug check has a value of 0x000001C5. This indicates a kernel mode threadpool encountered a deadlock situation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

IO_THREADPOOL_DEADLOCK_LIVEDUMP Parameters

PARAMETER	DESCRIPTION
1	Pool Number. 0x0 : ExPoolUntrusted
2	Pointer to the PEX_WORK_QUEUE
3	Reserved
4	Reserved

Bug Check 0xBFE: BC_BLUETOOTH_VERIFIER_FAULT

5/26/2017 • 1 min to read • [Edit Online](#)

The BC_BLUETOOTH_VERIFIER_FAULT bug check has a value of 0x00000BFE. This indicates that a driver has caused a violation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BC_BLUETOOTH_VERIFIER_FAULT Parameters

PARAMETER	DESCRIPTION
1	<p>The subtype of the Bluetooth verifier fault.</p> <div style="border: 1px solid black; padding: 5px;"><p>0x1 : An attempt was made to submit a Bluetooth Request Block that is already in use 2 - Brb pointer 3 - Reserved 4 - Reserved 0x2 : An attempt was made to free a Bluetooth Request Block that is in use 2 - Brb pointer 3 - Reserved 4 - Reserved 0x3 : An attempt was made to allocate or initialize an invalid BRB type 2 - Brb pointer 3 - pdo extension (if available) 4 - Reserved 0x4 : Invalid Bluetooth Request Block pointer was submitted 2 - Brb pointer 3 - Reserved 4 - Reserved 0x5 : A Bluetooth Request Block with an invalid size was submitted 2 - Brb pointer 3 - Actual Size 4 - Expected Size 0x6 : The IOCTL_BTH_GET_DEVICE_INFO was called with invalid parameters 2 - Reserved 3 - Reserved 4 - Reserved 0x7 : BRB_L2CA_UNREGISTER_SERVER was submitted with an invalid server handle 2 - Server handle 3 - Reserved 4 - Reserved 0x8 : BRB_L2CA_CLOSE_CHANNEL was submitted with an invalid channel handle 2 - Brb pointer 3 - Channel handle 4 - Reserved 0x9 : BRB_SCO_UNREGISTER_SERVER was submitted with an invalid server handle 2 - Server handle 3 - Reserved 4 - Reserved</p></div>
2	See parameter 1
3	See parameter 1
4	See parameter 1

Resolution

Parameter 1 describes the type of violation. Look at the call stack to determine the misbehaving driver.

Bug Check 0xBFF: BC_BTHMINI_VERIFIER_FAULT

5/26/2017 • 1 min to read • [Edit Online](#)

The BC_BTHMINI_VERIFIER_FAULT bug check has a value of 0x00000BFF. This indicates that The Bluetooth miniport extensible driver verifier has caught a violation.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

BC_BTHMINI_VERIFIER_FAULT Parameters

PARAMETER	DESCRIPTION
1	<p>The subtype of the Bluetooth verifier fault.</p> <div style="border: 1px solid black; padding: 5px;"><p>0x1 : An attempt was made to return a packet with type that mis-matched its original request. 2 - Returned packet type 3 - Expected packet type 4 - Reserved 0x2 : An attempt was made to return an unexpected status code and caused the packet to be discarded. 2 - Unexpected return status 3 - Reserved 4 - Reserved 0x3 : Incorrect output buffer size was returned to indicate number of bytes written by the lower transport driver. 2 - Unexpected buffer size 3 - Expected buffer size 4 - Reserved</p></div>
2	See parameter 1
3	See parameter 1
4	See parameter 1

Resolution

Parameter 1 describes the type of violation. Look at the call stack to determine the misbehaving driver.

Bug Check 0x20001: HYPERVISOR_ERROR

5/26/2017 • 1 min to read • [Edit Online](#)

The HYPERVISOR_ERROR bug check has a value of 0x00020001. This indicates that the hypervisor has encountered a fatal error.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

3	Reserved
4	Reserved

Bug Check 0x1000007E: SYSTEM_THREAD_EXCEPTION_NOT_HANDLED_M

5/26/2017 • 1 min to read • [Edit Online](#)

The SYSTEM_THREAD_EXCEPTION_NOT_HANDLED_M bug check has a value of 0x1000007E. This indicates that a system thread generated an exception which the error handler did not catch.

Bug check 0x1000007E has the same meaning and parameters as [bug check 0x7E](#) (SYSTEM_THREAD_EXCEPTION_NOT_HANDLED).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x1000007F: UNEXPECTED_KERNEL_MODE_TRAP_M

5/26/2017 • 1 min to read • [Edit Online](#)

The UNEXPECTED_KERNEL_MODE_TRAP_M bug check has a value of 0x1000007F. This indicates that a trap was generated by the Intel CPU and the kernel failed to catch this trap.

Bug check 0x1000007F has the same meaning and parameters as [bug check 0x7F](#) (UNEXPECTED_KERNEL_MODE_TRAP).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x1000008E: KERNEL_MODE_EXCEPTION_NOT_HANDLED_M

5/26/2017 • 1 min to read • [Edit Online](#)

The KERNEL_MODE_EXCEPTION_NOT_HANDLED_M bug check has a value of 0x1000008E. This indicates that a kernel-mode program generated an exception which the error handler did not catch.

Bug check 0x1000008E has the same meaning and parameters as [bug check 0x8E](#) (KERNEL_MODE_EXCEPTION_NOT_HANDLED).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x100000EA: THREAD_STUCK_IN_DEVICE_DRIVER_M

5/26/2017 • 1 min to read • [Edit Online](#)

The THREAD_STUCK_IN_DEVICE_DRIVER_M bug check has a value of 0x100000EA. This indicates that a thread in a device driver is endlessly spinning.

Bug check 0x100000EA has the same meaning and parameters as [bug check 0xEA](#) (THREAD_STUCK_IN_DEVICE_DRIVER).

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

Bug Check 0x4000008A: THREAD_TERMINATE_HELD_MUTEX

5/26/2017 • 1 min to read • [Edit Online](#)

The THREAD_TERMINATE_HELD_MUTEX bug check has a value of 0x4000008A. This indicates that a driver acquired a mutex on a thread that exited before the mutex could be released. This can be caused by a driver returning to user mode without releasing a mutex or by a driver acquiring a mutex and then causing an exception that results in the thread it is running on, being terminated.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

THREAD_TERMINATE_HELD_MUTEX Parameters

PARAMETER	DESCRIPTION
1	The address of the KTHREAD that owns the KMUTEX.
2	The address of the KMUTEX that is owned.
3	Reserved
4	Reserved

Cause

To investigate, look at the callstack. If there is a driver on the stack that is directly followed by system exception handling routines and then thread termination routines, this driver is at fault and needs to be fixed so that it does not cause an unhandled exception while holding a kernel mutex. If the stack just shows normal thread termination code and no driver is implicated, run **!pool** or use **In (List Nearest Symbols)** on the address of the mutex (parameter 2) and see if you can discover who owns the it. This bug will almost certainly be in the code of the owner of that mutex.

Bug Check 0xC0000218: STATUS_CANNOT_LOAD_REGISTRY_FILE

5/26/2017 • 1 min to read • [Edit Online](#)

The STATUS_CANNOT_LOAD_REGISTRY_FILE bug check has a value of 0xC0000218. This indicates that a registry file could not be loaded.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

STATUS_CANNOT_LOAD_REGISTRY_FILE Parameters

PARAMETER	DESCRIPTION
1	Address of the name of the registry hive that could not be loaded.
2	Zero (Reserved)
3	Zero (Reserved)
4	Zero (Reserved)

This bug check displays a descriptive text message. The name of the damaged file is displayed as part of the message.

Cause

This error occurs if a necessary registry hive file cannot be loaded. Usually this means the file is corrupt or is missing.

In rare instances, this error can be caused by a driver that has corrupted the registry image in memory, or by a memory error in this region.

Resolution

Try using the the startup recovery mechanism (for example Startup Repair, Recovery Console, or Emergency Recovery Disk) provided by the operating system. If the problem is a missing or corrupt registry file, that usually fixes the problem.

Bug Check 0xC000021A: STATUS_SYSTEM_PROCESS_TERMINATED

5/26/2017 • 3 min to read • [Edit Online](#)

The STATUS_SYSTEM_PROCESS_TERMINATED bug check has a value of 0xC000021A. This means that an error has occurred in a crucial user-mode subsystem.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

STATUS_SYSTEM_PROCESS_TERMINATED Parameters

PARAMETER	DESCRIPTION
1	A string that identifies the problem
2	The error code
3	Reserved
4	Reserved

Cause

This error occurs when a user-mode subsystem, such as WinLogon or the Client Server Run-Time Subsystem (CSRSS), has been fatally compromised and security can no longer be guaranteed. In response, the operating system switches to kernel mode. Microsoft Windows cannot run without WinLogon or CSRSS. Therefore, this is one of the few cases where the failure of a user-mode service can shut down the system.

Mismatched system files can also cause this error. This can occur if you have restored your hard disk from a backup. Some backup programs might skip restoring system files that they determine are in use.

Resolution

Running the kernel debugger is not useful in this situation because the actual error occurred in a user-mode process.

Resolving an error in a user-mode device driver, system service, or third-party application: Because bug check 0xC000021A occurs in a user-mode process, the most common culprits are third-party applications. If the error occurred after the installation of a new or updated device driver, system service, or third-party application, the new software should be removed or disabled to isolate the cause. Contact the manufacturer of the software about a possible update.

Resolving a mismatched system file problem: If you have recently restored your hard disk from a backup, check if there is an updated version of the Backup/Restore program available from the manufacturer.

These steps may be helpful in gathering additional information.

- Look at the most recently installed applications. To do this navigate to "Uninstall or change a program" in control panel and sort the installed applications by install date.
- Check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error. For more information, see [Open Event Viewer](#). Look for critical errors in the system log that occurred in the same time window as the blue screen.

These steps may be helpful in resolving this issue.

- Use the System File Checker tool to repair missing or corrupted system files. The System File Checker is a utility in Windows that allows users to scan for corruptions in Windows system files and restore corrupted files. Use the following command to run the System File Checker tool (SFC.exe).

```
SFC /scannow
```

For more information, see [Use the System File Checker tool to repair missing or corrupted system files](#).

- Run a virus detection program. Viruses can infect all types of hard disks formatted for Windows, and resulting disk corruption can generate system bug check codes. Make sure the virus detection program checks the Master Boot Record for infections.
- Verify that the system has the latest Service Pack installed. To detect which Service Pack, if any, is installed on your system, click **Start**, click **Run**, type **winver**, and then press ENTER. The **About Windows** dialog box displays the Windows version number and the version number of the Service Pack, if one has been installed.

Using Safe Mode

Consider using Safe Mode to isolate elements for troubleshooting and if necessary to use Windows. Using Safe Mode loads only the minimum required drivers and system services during the Windows startup. To enter Safe Mode, use **Update and Security** in Settings. Select **Recovery->Advanced startup** to boot to maintenance mode. At the resulting menu, choose **Troubleshoot-> Advanced Options -> Startup Settings -> Restart**. After Windows restarts to the **Startup Settings** screen, select option, 4, 5 or 6 to boot to Safe Mode.

Safe Mode may be available by pressing a function key on boot, for example F8. Refer to information from the manufacturer for specific startup options.

Bug Check 0xC0000221: STATUS_IMAGE_CHECKSUM_MISMATCH

5/26/2017 • 3 min to read • [Edit Online](#)

The STATUS_IMAGE_CHECKSUM_MISMATCH bug check has a value of 0xC0000221. This indicates that a driver or a system DLL has been corrupted.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

STATUS_IMAGE_CHECKSUM_MISMATCH Parameters

Cause

This bug check results from a serious error in a driver or other system file. The file header checksum does not match the expected checksum.

This can also be caused by faulty hardware in the I/O path to the file (a disk error, faulty RAM, or a corrupted page file).

Resolution

To remedy this error, run the Emergency Recovery Disk (ERD) and allow the system to repair or replace the missing or damaged driver file on the system partition.

You can also run an in-place upgrade over the existing copy of Windows. This preserves all registry settings and configuration information, but replaces all system files. If any Service Packs and/or hotfixes had previously been applied, you need to reinstall them afterward in the appropriate order (latest Service Pack, then any post-Service Pack hotfixes in the order in which they were originally installed, if applicable).

If a specific file was identified in the bug check message as being corrupted, you can try replacing that individual file manually. If the system partition is formatted with FAT, you can start from an MS-DOS startup disk and copy the file from the original source onto the hard disk. If you have a dual-boot machine, you can boot to your other operating system and replace the file.

If you want to replace the file on a single-boot system with an NTFS partition, you need to restart the system, press F8 at the operating system **Loader** menu, and choose **Safe Mode with Command Prompt**. From there, copy a fresh version of the file from the original source onto the hard disk. If the file is used as part of the system startup process in Safe Mode, you need to start the computer using the Recovery Console in order to access the file. If these methods fail, try reinstalling Windows and then restoring the system from a backup.

Note If the original file from the product CD has a filename extension ending in an _ (underscore), the file needs to be uncompressed before it can be used. The Recovery Console's **Copy** command automatically detects compressed files and expands them as they are copied to the target location. If you are using Safe Mode to access a drive, use the **Expand** command to uncompress and copy the file to the target folder. You can use the **Expand** command in the command line environment of Safe Mode.

Resolving a disk error problem: Disk errors can be a source of file corruption. Run **Chkdsk /f /r** to detect and resolve any file system structural corruption. You must restart the system before the disk scan begins on a system partition.

Resolving a RAM problem: If the error occurred immediately after RAM was added to the system, the paging file might be corrupted or the new RAM itself might be either faulty or incompatible.

To determine if newly added RAM is causing a bug check

1. Return the system to the original RAM configuration.
2. Use the Recovery Console to access the partition containing the paging file and delete the file pagefile.sys.
3. While still in the Recovery Console, run **Chkdsk /r** on the partition that contained the paging file.
4. Restart the system.
5. Set the paging file to an optimal level for the amount of RAM added.
6. Shutdown the system and add your RAM.

The new RAM must meet the system manufacturer's specifications for speed, parity, and type (that is, fast page-mode (FPM) versus extended data out (EDO) versus synchronous dynamic random access memory (SDRAM)). Try to match the new RAM to the existing installed RAM as closely as possible. RAM can come in many different capacities, and more importantly, in different formats (single inline memory modules -- SIMM -- or dual inline memory modules -- DIMM). The electrical contacts can be either gold or tin and it is not wise to mix these contact types.

If you experience the same error message after reinstalling the new RAM, run hardware diagnostics supplied by the system manufacturer, especially the memory scanner. For details on these procedures, see the owner's manual for your computer.

When you can log on to the system again, check the System Log in Event Viewer for additional error messages that might help pinpoint the device or driver that is causing the error.

Disabling memory caching of the BIOS might also resolve this error.

Bug Check 0xDEADDEAD: MANUALLY_INITIATED_CRASH1

5/26/2017 • 1 min to read • [Edit Online](#)

The MANUALLY_INITIATED_CRASH1 bug check has a value of 0xDEADDEAD. This indicates that the user deliberately initiated a crash dump from either the kernel debugger or the keyboard.

Important This topic is for programmers. If you are a customer who has received a blue screen error code while using your computer, see [Troubleshoot blue screen errors](#).

MANUALLY_INITIATED_CRASH1 Parameters

None

Remarks

For details on manually-initiated crash dumps, see [Forcing a System Crash](#).

Debugger Reference

CDB Command-Line Options

5/31/2017 • 15 min to read • [Edit Online](#)

First-time users of CDB or NTSD should begin with the [Debugging Using CDB and NTSD](#) section.

The CDB command line uses the following syntax:

```
cdb [ -server ServerTransport | -remote ClientTransport ]
[ -premove SmartClientTransport ] [-log{a|au|o|ou} LogFile]
[-2] [-d] [-ddefer] [-g] [-G] [-hd] [-lines] [-myob] [-bonc]
[-n] [-o] [-s] [-v] [-w] [-cf "filename"] [-cfr "filename"] [-c "command"]
[-robp] [-r BreakErrorLevel] [-t PrintErrorLevel]
[-x{e|d|n|i} Exception] [-x] [-clines lines]
[-i ImagePath] [-y SymbolPath] [-srcpath SourcePath]
[-aExtension] [-failinc] [-noio] [-noinh] [-noshell] [-nosqm]
[-sdce] [-ses] [-sicc] [-sins] [-snc] [-snul] [-zp PageFile]
[-sup] [-sflags 0xNumber] [-ee {masm|c++}]
[-e Event] [-pb] [-pd] [-pe] [-pr] [-pt Seconds] [-pv]
[ -- | -p PID | -pn Name | -psn ServiceName | -z DumpFile | executable ]
[-cimp] [-isd] [-kqm] [-pvr] [-version] [-vf] [-vf:<opts>] [-netsyms:{yes|no}]

cdb -iae

cdb -iaec KeyString

cdb -iu KeyString

cdb -QR Server

cdb -wake pid

cdb -?
```

The NTSD command-line syntax is identical to that of CDB:

```

ntsd [ -server ServerTransport | -remote ClientTransport ]
[ -premove SmartClientTransport ] [-log{a|au|o|ou} LogFile]
[-2] [-d] [-ddefer] [-g] [-G] [-hd] [-lines] [-myob] [-bonc]
[-n] [-o] [-s] [-v] [-w] [-cf "filename"] [-cfr "filename"] [-c "command"]
[-robp] [-r BreakErrorLevel] [-t PrintErrorLevel]
[-x{e|d|n|i} Exception] [-x] [-clines lines]
[-i ImagePath] [-y SymbolPath] [-srcpath SourcePath]
[-aExtension] [-failinc] [-noio] [-noinh] [-noshell] [-nosqm]
[-sdce] [-ses] [-sicv] [-sins] [-snc] [-snul] [-zp PageFile]
[-sup] [-sflags 0xNumber] [-ee {masm|c++}]
[-e Event] [-pb] [-pd] [-pe] [-pr] [-pt Seconds] [-pv]
[ -- | -p PID | -pn Name | -psn ServiceName | -z DumpFile | executable ]
[-cimp] [-isd] [-kqm] [-pvr] [-version] [-vf] [-vf:<opts>] [-netsyms:{yes|no}]

ntsd -iae

ntsd -iaec KeyString

ntsd -iu KeyString

ntsd -QR Server

ntsd -wake PID

ntsd -?

```

The only difference between NTSD and CDB is that NTSD spawns a new console window while CDB inherits the window from which it was invoked. Since the **start** command can also be used to spawn a new console window, the following two constructions will give the same results:

```

start cdb [parameters]
ntsd [parameters]

```

Descriptions of the CDB and NTSD command-line options follow. Only the **-remote**, **-server**, **-g** and **-G** options are case-sensitive. The initial hyphen can be replaced with a forward-slash (/). Options that do not take any additional parameters can be concatenated -- so **cdb -o -d -G -g winmine** can be written as **cdb -odGg winmine**.

If the **-remote** or **-server** option is used, it must appear before any other options on the command line. If an *executable* is specified, it must appear last on the command line; any text after the *executable* name is passed to the executable program as its own command-line parameters.

Parameters

-server *ServerTransport*

Creates a debugging server that can be accessed by other debuggers. For an explanation of the possible *ServerTransport* values, see [Activating a Debugging Server](#). When this parameter is used, it must be the first parameters on the command line.

-remote *ClientTransport*

Creates a debugging client, and connects to a debugging server that is already running. For an explanation of the possible *ClientTransport* values, see [Activating a Debugging Client](#). When this parameter is used, it must be the first parameters on the command line.

-premove *SmartClientTransport*

Creates a smart client, and connects to a process server that is already running. For an explanation of the possible *SmartClientTransport* values, see [Activating a Smart Client](#).

If the target application is a *console application*, this option causes it to live in a new console window. (The default is for a target console application to share the window with CDB or NTSD.)

--

Debugs the Client Server Run-Time Subsystem (CSRSS). For details, see [Debugging CSRSS](#).

-a Extension

Sets the default extension DLL. The default is *userexts*. There must be no space after the "a", and the .dll extension must not be included. For details, and other methods of setting this default, see [Loading Debugger Extension DLLs](#).

-bонc

If this option is specified, the debugger will break into the target as soon as the session begins. This is especially useful when connecting to a debugging server that might not be currently broken into the target.

-c " command "

Specifies the initial debugger command to run at start-up. This command must be surrounded with quotation marks. Multiple commands can be separated with semicolons. (If you have a long command list, it may be easier to put them in a script and then use the **-c** option with the [\\$<, \\$><, \\$><, \\$\\$>< \(Run Script File\)](#) command.)

If you are starting a debugging client, this command must be intended for the debugging server. Client-specific commands such as **.Isrcpath** are not allowed.

-cf " filename "

Specifies the path and name of a script file. This script file is executed as soon as the debugger is started. If *filename* contains spaces it must be enclosed in quotation marks. If the path is omitted, the current directory is assumed. If the **-cf** option is not used, the file ntsd.ini in the current directory is used as the script file. If the file does not exist, no error occurs. For details, see [Using Script Files](#).

-cfr " filename "

Specifies the path and name of a script file. This script file is executed as soon as the debugger is started, and any time the target is restarted. If *filename* contains spaces it must be enclosed in quotation marks. If the path is omitted, the current directory is assumed. If the file does not exist, no error occurs. For details, see [Using Script Files](#).

-cimp

Directs CDB/NTSD to start with a DbgSrv implicit command line instead of an explicit process to run. This option is the client side of dbgsrv -pc.

-clines lines

Sets the approximate number of commands in the command history which can be accessed during remote debugging. For details, and for other ways to change this number, see [Using Debugger Commands](#).

-d

Passes control of this debugger to the kernel debugger. If you are debugging CSRSS, this control redirection always is active, even if **-d** is not specified. (This option cannot be used during remote debugging -- use **-ddefer** instead.) See [Controlling the User-Mode Debugger from the Kernel Debugger](#) for details. This option cannot be used in conjunction with either the **-ddefer** option or the **-noio** option.

Note If you use WinDbg as the kernel debugger, many of the familiar features of WinDbg are not available in this scenario. For example, you cannot use the Locals window, the Disassembly window, or the Call Stack window, and you cannot step through source code. This is because WinDbg is only acting as a viewer for the debugger (NTSD or CDB) running on the target computer.

-ddefer

Passes control of this debugger to the kernel debugger, unless a debugging client is connected. (This is a

variation of **-d** that can be used from a debugging server.) See [Controlling the User-Mode Debugger from the Kernel Debugger](#) for details. This option cannot be used in conjunction with either the **-d** option or the **-noio** option.

-e Event

Signals the debugger that the specified event has occurred. This option is only used when starting the debugger programmatically.

-ee {masm|c++}

Sets the default expression evaluator. If **masm** is specified, MASM expression syntax will be used. If **c++** is specified, C++ expression syntax will be used. If the **-ee** option is omitted, MASM expression syntax is used as the default. See [Evaluating Expressions](#) for details.

-failinc

Causes the debugger to ignore any questionable symbols. When debugging a user-mode or kernel-mode minidump file, this option will also prevent the debugger from loading any modules whose images can't be mapped. For details and for other methods of controlling this, see [SYMOPT_EXACT_SYMBOLS](#).

-g

Ignores the initial breakpoint in target application. This option will cause the target application to continue running after it is started or CDB attaches to it, unless another breakpoint has been set. See [Initial Breakpoint](#) for details.

-G

Ignores the final breakpoint at process termination. By default, CDB stops during the image run-down process. This option will cause CDB to exit immediately when the child terminates. This has the same effect as entering the command **sxd epr**. For more information, see [Controlling Exceptions and Events](#).

-hd

(Microsoft Windows XP and later) Specifies that the debug heap should not be used. See [Debugging a User-Mode Process Using CDB](#) for details.

-i ImagePath

Specifies the location of the executables that generated the fault. If the path contains spaces, it should be enclosed in quotation marks.

-iae

Installs CDB as the postmortem debugger. For details, see [Enabling Postmortem Debugging](#).

If this action succeeds, no message is displayed; if it fails, an error message is displayed.

The **-iae** parameter must not be used with any other parameters. This command will not actually start CDB.

-iaeC KeyString

Installs CDB as the postmortem debugger. The contents of *KeyString* will be appended to the end of the **AeDebug** registry key. If *KeyString* contains spaces, it must be enclosed in quotation marks. For details, see [Enabling Postmortem Debugging](#).

If this action succeeds, no message is displayed; if it fails, an error message is displayed.

The **-iaeC** parameter must not be used with any other parameters. This command will not actually start CDB.

-isd

Turns on the `CREATE_IGNORE_SYSTEM_DEFAULT` flag for any process creations.

-iu KeyString

Registers debugger remoting as an URL type so that users can auto-launch a debugger remote client with an URL. *KeyString* has the format `remdbgeng://RemotingOption`. *RemotingOption* is a string that defines the

transport protocol as defined in the topic [Activating a Debugging Client](#). If this action succeeds, no message is displayed; if it fails, an error message is displayed.

The **-iu** parameter must not be used with any other parameters. This command will not actually start CDB.

-kqm

Starts CDB/NTSD in quiet mode.

-lines

Enables source line debugging. If this option is omitted, the [.lines \(Toggle Source Line Support\)](#) command will have to be used before source debugging will be allowed. For other methods of controlling this, see [SYMOPT_LOAD_LINES](#).

-log{a|au|o|ou} LogFile

Begins logging information to a log file. If the specified file already exists, it will be overwritten if **-logo** is used, or output will be appended to the file if **-loga** is used. The **-logau** and **-logou** options operate similar to **-loga** and **-logo** respectively, except that the log file is a Unicode file. For more details, see [Keeping a Log File in CDB](#).

-myob

If there is a version mismatch with dbghelp.dll, the debugger will continue to run. (Without the **-myob** switch, this is considered a fatal error.)

-n

Noisy symbol load: Enables verbose output from the symbol handler. For details and for other methods of controlling this, see [SYMOPT_DEBUG](#).

-netsyms {yes|no}

Allow or disallow loading symbols from a network path.

-noinh

Prevents processes created by the debugger from inheriting handles from the debugger. For other methods of controlling this, see [Debugging a User-Mode Process Using CDB](#).

-noio

Prevents the debugging server from being used for input or output. Input will only be accepted from the debugging client (plus any initial command or command script specified by the **-c** command-line option).

All output will be directed to the debugging client. If NTSD is used for the server, no console window will be created at all. For more details, see [Activating a Debugging Server](#). This option cannot be used in conjunction with either the **-d** option or the **-ddefer** option.

-noshell

Prohibits all **.shell** commands. This prohibition will last as long as the debugger is running, even if a new debugging session is begun. For details, and for other ways to disable **.shell** commands, see [Using Shell Commands](#).

-nosqm

Disables telemetry data collection and upload.

-o

Debugs all processes launched by the target application (child processes). By default, processes created by the one you are debugging will run as they normally do. For other methods of controlling this, see [Debugging a User-Mode Process Using CDB](#).

-p PID

Specifies the decimal process ID to be debugged. This is used to debug a process that is already running. For details, see [Debugging a User-Mode Process Using CDB](#).

-pb

(Windows XP and later) Prevents the debugger from requesting an initial break-in when attaching to a target process. This can be useful if the application is already suspended, or if you wish to avoid creating a break-in thread in the target.

-pd

(Windows XP and later) Causes the target application not to be terminated at the end of the debugging session. See [Ending a Debugging Session in CDB](#) for details.

-pe

(Windows XP and later) Indicates that the target application is already being debugged. See [Re-attaching to the Target Application](#) for details.

-pn *Name*

Specifies the name of the process to be debugged. (This name must be unique.) This is used to debug a process that is already running.

-pr

(Windows XP and later) Causes the debugger to start the target process running when it attaches to it. This can be useful if the application is already suspended and you wish it to resume execution.

-psn *ServiceName*

Specifies the name of a service contained in the process to be debugged. This is used to debug a process that is already running.

-pt *Seconds*

Specifies the break time-out, in seconds. The default is 30. See [Controlling the Target](#) for details.

-pv

Specifies that the debugger should attach to the target process noninvasively. For details, see [Noninvasive Debugging \(User Mode\)](#).

-pvr

Works like **-pv** except that the target process is not suspended.

-QR *Server*

Lists all debugging servers running on the specified network server. The double backslash (\) preceding *Server* is optional. See [Searching for Debugging Servers](#) for details.

The **-QR** parameter cannot be used with any other parameters. This command will not actually start CDB.

-r *BreakErrorLevel*

Specifies the error level that will cause the target to break into the debugger. This is a decimal number equal to 0, 1, 2, or 3. Possible values are as follows:

VALUE	CONSTANT	MEANING
0	NONE	Do not break on any errors.
1	ERROR	Break on ERROR level debugging events.
2	MINORERROR	Break on MINORERROR and ERROR level debugging events.

VALUE	CONSTANT	MEANING
3	WARNING	Break on WARNING, MINORERROR, and ERROR level debugging events.

This error level only has meaning in checked builds of Microsoft Windows. The default value is 1.

-robp

This allows CDB to set a breakpoint on a read-only memory page. (The default is for such an operation to fail.)

-s

Disables lazy symbol loading. This will slow down process startup. For details and for other methods of controlling this, see [SYMOPT_DEFERRED_LOADS](#).

-sdce

Causes the debugger to display **File access error** dialog boxes during symbol load. For details and for other methods of controlling this, see [SYMOPT_FAIL_CRITICAL_ERRORS](#).

-ses

Causes the debugger to perform a strict evaluation of all symbol files and ignore any questionable symbols. For details and for other methods of controlling this, see [SYMOPT_EXACT_SYMBOLS](#).

-sflags 0x Number

Sets all the symbol handler options at once. *Number* should be a hexadecimal number prefixed with **0x** -- a decimal without the **0x** is permitted, but the symbol options are binary flags and therefore hexadecimal is recommended. This option should be used with care, since it will override all the symbol handler defaults. For details, see [Setting Symbol Options](#).

-sicv

Causes the symbol handler to ignore the CV record. For details and for other methods of controlling this, see [SYMOPT_IGNORE_CVREC](#).

-sins

Causes the debugger to ignore the symbol path and executable image path environment variables. For details, see [SYMOPT_IGNORE_NT_SYMPATH](#).

-snc

Causes the debugger to turn off C++ translation. For details and for other methods of controlling this, see [SYMOPT_NO_CPP](#).

-snul

Disables automatic symbol loading for unqualified names. For details and for other methods of controlling this, see [SYMOPT_NO_UNQUALIFIED_LOADS](#).

-srcpath SourcePath

Specifies the source file search path. Separate multiple paths with a semicolon (;). If the path contains spaces, it should be enclosed in quotation marks. For details, and for other ways to change this path, see [Source Path](#).

-sup

Causes the symbol handler to search the public symbol table during every symbol search. For details and for other methods of controlling this, see [SYMOPT_AUTO_PUBLICS](#).

-t PrintErrorLevel

Specifies the error level that will cause the debugger to display an error message. This is a decimal number equal to 0, 1, 2, or 3. Possible values are as follows:

VALUE	CONSTANT	MEANING
0	NONE	Do not display any errors.
1	ERROR	Display ERROR level debugging events.
2	MINORERROR	Display MINORERROR and ERROR level debugging events.
3	WARNING	Display WARNING, MINORERROR, and ERROR level debugging events.

This error level only has meaning in checked builds of Microsoft Windows. The default value is 1.

-v

Enables verbose output from the debugger.

-version

Prints the debugger version string.

-vf

Enables default ApplicationVerifier settings.

-vf: <opts>

Enables given ApplicationVerifier settings.

-w

Specifies to debug 16-bit applications in a separate VDM.

-wake PID

Causes sleep mode to end for the user-mode debugger whose process ID is specified by *PID*. This command must be issued on the target machine during sleep mode. See [Controlling the User-Mode Debugger from the Kernel Debugger](#) for details.

The **-wake** parameter should not be used with any other parameters. This command will not actually start CDB.

-x{e|d|n|i} Exception

Controls the debugger's behavior when the specified event occurs. The *Exception* can be either an exception number or an event code. You can specify this option multiple times to control different events. See [Controlling Exceptions and Events](#) for details and for other methods of controlling these settings.

-x

Disables first-chance break on access violation exceptions. The second occurrence of an access violation will break into the debugger. This is the same as **-xd av**.

-y SymbolPath

Specifies the symbol search path. Separate multiple paths with a semicolon (;). If the path contains spaces, it should be enclosed in quotation marks. For details, and for other ways to change this path, see [Symbol Path](#).

-z DumpFile

Specifies the name of a crash dump file to debug. If the path and file name contain spaces, this must be surrounded by quotation marks. It is possible to open several dump files at once by including multiple **-z**

options, each followed by a different *DumpFile* value. For details, see [Analyzing a User-Mode Dump File with CDB](#).

-zp *PageFile*

Specifies the name of a modified page file. This is useful if you are debugging a dump file and want to use the [.pagein \(Page In Memory\)](#) command. You cannot use **-zp** with a standard Windows page file -- only specially-modified page files can be used.

executable

Specifies the command line of an executable process. This is used to launch a new process and debug it. This has to be the final item on the command line. All text after the executable name is passed to the executable as its argument string.

-?

Displays command-line help text.

When you are starting the debugger from **Start | Run** or from a Command Prompt window, specify arguments for the target application after the application's file name. For instance:

```
cdb myexe arg1arg2
```

[Send comments about this topic to Microsoft](#)

KD Command-Line Options

5/31/2017 • 9 min to read • [Edit Online](#)

First-time users of KD should begin with the [Debugging Using KD and NTKD](#) section.

The KD command line uses the following syntax.

```
kd [ -server ServerTransport | -remote ClientTransport ]
  [-b | -x] [-d] [-bonc] [-m] [-myob] [-lines] [-n] [-r] [-s]
  [-v] [-clines lines] [-failinc] [-noio] [-noshell]
  [-secure] [-sdce] [-ses] [-sicv] [-sins] [-snc] [-snul]
  [-sup] [-sflags 0xNumber] [-log{a|au|o|ou}LogFile]
  [-aExtension] [-zp PageFile]
  [-i ImagePath] [-y SymbolPath] [-srcpath SourcePath]
  [-k ConnectType | -k1 | -kqm | -kx ExdiOptions] [-ee {masm|c++}]
  [-z DumpFile] [-cf "filename"] [-cfr "filename"] [-c "command"]
  [-t PrintErrorLevel] [-version]

kd -iu KeyString

kd -QR Server

kd -wake PID

kd -?
```

Descriptions of the KD command-line options follow. Only the **-remote** and **-server** options are case-sensitive. The initial hyphen can be replaced with a forward-slash (/). Options which do not take any additional parameters can be concatenated -- so **kd -r -n -v** can be written as **kd -rnv**.

If the **-remote** or **-server** option is used, it must appear before any other options on the command line.

Parameters

-server *ServerTransport*

Creates a debugging server that can be accessed by other debuggers. For an explanation of the possible *ServerTransport*, see [Activating a Debugging Server](#). When this parameter is used, it must be the first parameters on the command line.

-remote *ClientTransport*

Creates a debugging client, and connects to a debugging server that is already running. For an explanation of the possible *ClientTransport* values, see [Activating a Debugging Client](#). When this parameter is used, it must be the first parameters on the command line.

-a *Extension*

Sets the default extension DLL. The default is kdextx86.dll or kdexts.dll. There must be no space after the "a", and the .dll file name extension must not be included. For details, and other methods of setting this default, see [Loading Debugger Extension DLLs](#).

-b

This option no longer supported.

-bonc

If this option is specified, the debugger will break into the target as soon as the session begins. This is especially useful when connecting to a debugging server that might not be currently broken into the target.

-c "command"

Specifies the initial debugger command to run at start-up. This command must be surrounded with quotation marks. Multiple commands can be separated with semicolons. (If you have a long command list, it may be easier to put them in a script and then use the **-c** option with the **\$<, \$><, \$><, \$\$>< (Run Script File)** command.)

If you are starting a debugging client, this command must be intended for the debugging server. Client-specific commands, such as **.lsrcpath**, are not allowed.

-cf "filename"

Specifies the path and name of a script file. This script file is executed as soon as the debugger is started. If *filename* contains spaces it must be enclosed in quotation marks. If the path is omitted, the current directory is assumed. If the **-cf** option is not used, the file ntsd.ini in the current directory is used as the script file. If the file does not exist, no error occurs. For details, see [Using Script Files](#).

-cfr "filename"

Specifies the path and name of a script file. This script file is executed as soon as the debugger is started, and any time the target is restarted. If *filename* contains spaces it must be enclosed in quotation marks. If the path is omitted, the current directory is assumed. If the file does not exist, no error occurs. For details, see [Using Script Files](#).

-clines *lines*

Sets the approximate number of commands in the command history which can be accessed during remote debugging. For details, and for other ways to change this number, see [Using Debugger Commands](#).

-d

After a reboot, the debugger will break into the target computer as soon as a kernel module is loaded. (This break is earlier than the break from the **-b** option.) See [Crashing and Rebooting the Target Computer](#) for details and for other methods of changing this status.

-ee {masm|c++}

Sets the default expression evaluator. If **masm** is specified, MASM expression syntax will be used. If **c++** is specified, C++ expression syntax will be used. If the **-ee** option is omitted, MASM expression syntax is used as the default. See [Evaluating Expressions](#) for details.

-failinc

Causes the debugger to ignore any questionable symbols. When debugging a user-mode or kernel-mode minidump file, this option will also prevent the debugger from loading any modules whose images can't be mapped. For details and for other methods of controlling this, see [SYMOPT_EXACT_SYMBOLS](#).

-i *ImagePath*

Specifies the location of the executables that generated the fault. If the path contains spaces, it should be enclosed in quotation marks.

-iu *KeyString*

Registers debugger remoting as an URL type so that users can auto-launch a debugger remote client with an URL. *KeyString* has the format `remdbgeng://RemotingOption`. *RemotingOption* is a string that defines the transport protocol as defined in the topic [Activating a Debugging Client](#). If this action succeeds, no message is displayed; if it fails, an error message is displayed.

The **-iu** parameter must not be used with any other parameters. This command will not actually start KD.

-k *ConnectType*

Tells the debugger how to connect to the target. For details, see [Debugging Using KD and NTKD](#).

-kl

(Windows XP and later) Starts a kernel debugging session on the same machine as the debugger.

-kqm

Starts KD in quiet mode.

-kx *ExdiOptions*

Starts a kernel debugging session using an EXDI driver. EXDI drivers are not described in this documentation. If you have an EXDI interface to your hardware probe or hardware simulator, please contact Microsoft for debugging information.

-lines

Enables source line debugging. If this option is omitted, the [.lines \(Toggle Source Line Support\)](#) command will have to be used before source debugging will be allowed. For other methods of controlling this, see [SYMOPT_LOAD_LINES](#).

-log{a|au|o|ou} *LogFile*

Begins logging information to a log file. If *LogFile* already exists, it will be overwritten if **-logo** is used, or output will be appended to the file if **-loga** is used. The **-logau** and **-logou** options operate similar to **-loga** and **-logo** respectively, except that the log file is a Unicode file. For more details, see [Keeping a Log File in KD](#).

-m

Indicates that the serial port is connected to a modem. Instructs the debugger to watch for the carrier-detect signal.

-myob

If there is a version mismatch with dbghelp.dll, the debugger will continue to run. (Without the **-myob** switch, this is considered a fatal error.)

A secondary effect of this option is that the warning that normally appears when breaking into the target computer is suppressed.

-n

Noisy symbol load: Enables verbose output from symbol handler. For details and for other methods of controlling this, see [SYMOPT_DEBUG](#).

-noio

Prevents the debugging server from being used for input or output. Input will only be accepted from the debugging client (plus any initial command or command script specified by the **-c** command-line option).

All output will be directed to the debugging client. For more details, see [Activating a Debugging Server](#).

-noshell

Prohibits all **.shell** commands. This prohibition will last as long as the debugger is running, even if a new debugging session is begun. For details, and for other ways to disable shell commands, see [Using Shell Commands](#).

-QR *Server*

Lists all debugging servers running on the specified network server. The double backslash (\\\) preceding *Server* is optional. See [Searching for Debugging Servers](#) for details.

The **-QR** parameter must not be used with any other parameters. This command will not actually start KD.

-r

Displays registers.

-s

Disables lazy symbol loading. This will slow down process startup. For details and for other methods of controlling this, see [SYMOPT_DEFERRED_LOADS](#).

-sdce

Causes the debugger to display **File access error** dialog boxes during symbol load. For details and for other

methods of controlling this, see [SYMOPT_FAIL_CRITICAL_ERRORS](#).

-secure

Activates [Secure Mode](#).

-ses

Causes the debugger to perform a strict evaluation of all symbol files and ignore any questionable symbols. For details and for other methods of controlling this, see [SYMOPT_EXACT_SYMBOLS](#).

-sflags *0xNumber*

Sets all the symbol handler options at once. *Number* should be a hexadecimal number prefixed with **0x** -- a decimal without the **0x** is permitted, but the symbol options are binary flags and therefore hexadecimal is recommended. This option should be used with care, since it will override all the symbol handler defaults. For details, see [Setting Symbol Options](#).

-sicv

Causes the symbol handler to ignore the CV record. For details and for other methods of controlling this, see [SYMOPT_IGNORE_CVREC](#).

-sins

Causes the debugger to ignore the symbol path and executable image path environment variables. For details, see [SYMOPT_IGNORE_NT_SYMPATH](#).

-snc

Causes the debugger to turn off C++ translation. For details and for other methods of controlling this, see [SYMOPT_NO_CPP](#).

-snul

Disables automatic symbol loading for unqualified names. For details and for other methods of controlling this, see [SYMOPT_NO_UNQUALIFIED_LOADS](#).

-srcpath *SourcePath*

Specifies the source file search path. Separate multiple paths with a semicolon (;). If the path contains spaces, it should be enclosed in quotation marks. For details, and for other ways to change this path, see [Source Path](#).

-sup

Causes the symbol handler to search the public symbol table during every symbol search. For details and for other methods of controlling this, see [SYMOPT_AUTO_PUBLICS](#).

-t *PrintErrorLevel*

Specifies the error level that will cause the debugger to display an error message. This is a decimal number equal to 0, 1, 2, or 3. The values are described as follows:

VALUE	CONSTANT	MEANING
0	NONE	Do not display any errors.
1	ERROR	Display ERROR level debugging events.
2	MINORERROR	Display MINORERROR and ERROR level debugging events.

Value	Constant	Meaning
3	WARNING	Display WARNING, MINORERROR, and ERROR level debugging events.

This error level only has meaning in checked builds of Microsoft Windows. The default value is 1.

-v

Generates verbose messages for loads, deferred loads, and unloads.

-version

Prints the debugger version string.

-wake *PID*

Causes sleep mode to end for the user-mode debugger whose process ID is specified by *PID*. This command must be issued on the target machine during sleep mode. See [Controlling the User-Mode Debugger from the Kernel Debugger](#) for details.

The **-wake** parameter must not be used with any other parameters. This command will not actually start KD.

-x

Causes the debugger to break in when an exception first occurs, rather than letting the application or module that caused the exception deal with it. (Same as **-b**, except with an initial **eb nt!NtGlobalFlag 9:g** command.)

-y *SymbolPath*

Specifies the symbol search path. Separate multiple paths with a semicolon (;). If the path contains spaces, it should be enclosed in quotation marks. For details, and for other ways to change this path, see [Symbol Path](#).

-z *DumpFile*

Specifies the name of a crash dump file to debug. If the path and file name contain spaces, this must be surrounded by quotation marks. It is possible to open several dump files at once by including multiple **-z** options, each followed by a different *DumpFile* value. For details, see [Analyzing a Kernel-Mode Dump File with KD](#).

-zp *PageFile*

Specifies the name of a modified page file. This is useful if you are debugging a dump file and want to use the [.pagein \(Page In Memory\)](#) command. You cannot use **-zp** with a standard Windows page file—only specially-modified page files can be used.

-?

Displays command-line help text.

KD will automatically detect the platform on which the target is running. You do not need to specify the target on the KD command line. The older syntax (using the name *I386KD* or *IA64KD*) is obsolete.

[Send comments about this topic to Microsoft](#)

WinDbg Command-Line Options

5/31/2017 • 11 min to read • [Edit Online](#)

First-time users of WinDbg should begin with the [Debugging Using WinDbg](#) section.

The WinDbg command line uses the following syntax:

```
windbg [ -server ServerTransport | -remote ClientTransport ] [-lsrcpath ]
[ -premote SmartClientTransport ] [-?] [-ee {masm|c++}]
[-clines lines] [-b] [-d] [-aExtension]
[-failinc] [-g] [-G] [-hd] [-j] [-n] [-noshell] [-o]
[-Q | -QY] [-QS | -QSY] [-robp] [-secure] [-ses] [-sdce]
[-sicc] [-sins] [-snc] [-snul] [-sup] [-sflags 0xNumber]
[-T Title] [-v] [-log{o|a}LogFile] [-noinh]
[-i ImagePath] [-y SymbolPath] [-srcpath SourcePath]
[-k [ConnectType] | -k1 | -kx ExdiOptions] [-c "command"]
[-pb] [-pd] [-pe] [-pr] [-pt Seconds] [-pv]
[-W Workspace] [-WF Filename] [-WX] [-zp PageFile]
[ -p PID | -pn Name | -psn ServiceName | -z DumpFile | executable ]

windbg -I[S]

windbg -IU KeyString

windbg -IA[S]
```

Descriptions of the WinDbg command-line options follow. All command-line options are case-sensitive except for **-j**. The initial hyphen can be replaced with a forward-slash (/).

If the **-remote** or **-server** option is used, it must appear before any other options on the command line. If an *executable* is specified, it must appear last on the command line; any text after the *executable* name is passed to the executable program as its own command-line parameters.

Parameters

-server *ServerTransport*

Creates a debugging server that can be accessed by other debuggers. For an explanation of the possible *ServerTransport* values, see [Activating a Debugging Server](#). When this parameter is used, it must be the first parameters on the command line.

-remote *ClientTransport*

Creates a debugging client, and connects to a debugging server that is already running. For an explanation of the possible *ClientTransport* values, see [Activating a Debugging Client](#). When this parameter is used, it must be the first parameters on the command line.

-premote *SmartClientTransport*

Creates a smart client, and connects to a process server that is already running. For an explanation of the possible *SmartClientTransport* values, see [Activating a Smart Client](#).

-a *Extension*

Sets the default extension DLL. The default is kdextx86.dll or kdexts.dll. There must be no space after the "a", and the .dll file name extension must not be included. For details, and other methods of setting this default, see [Loading Debugger Extension DLLs](#).

-b

This option is no longer supported.

-c " command "

Specifies the initial debugger command to run at start-up. This command must be enclosed in quotation marks. Multiple commands can be separated with semicolons. (If you have a long command list, it may be easier to put them in a script and then use the **-c** option with the [\\$<, \\$><, \\$><, \\$\\$>< \(Run Script File\)](#) command.)

If you are starting a debugging client, this command must be intended for the debugging server. Client-specific commands, such as **.lsrcpath**, are not allowed.

-clines lines

Sets the approximate number of commands in the command history which can be accessed during remote debugging. For details, and for other ways to change this number, see [Using Debugger Commands](#).

-d

(Kernel mode only) After a reboot, the debugger will break into the target computer as soon as a kernel module is loaded. (This break is earlier than the break from the **-b** option.) See [Crashing and Rebooting the Target Computer](#) for details and for other methods of changing this status.

-ee {masm|c++}

Sets the default expression evaluator. If **masm** is specified, MASM expression syntax will be used. If **c++** is specified, C++ expression syntax will be used. If the **-ee** option is omitted, MASM expression syntax is used as the default. See [Evaluating Expressions](#) for details.

-failinc

Causes the debugger to ignore any questionable symbols. When debugging a user-mode or kernel-mode minidump file, this option will also prevent the debugger from loading any modules whose images can't be mapped. For details and for other methods of controlling this, see [SYMOPT_EXACT_SYMBOLS](#).

-g

(User mode only) Ignores the initial breakpoint in target application. This option will cause the target application to continue running after it is started or WinDbg attaches to it, unless another breakpoint has been set. See [Initial Breakpoint](#) for details.

-G

(User mode only) Ignores the final breakpoint at process termination. Typically, the debugging session ends during the image run-down process. This option will cause the debugging session to end immediately when the child terminates. This has the same effect as entering the command **sxd epr**. For more information, see [Controlling Exceptions and Events](#).

-hd

(Windows XP and later, user mode only) Specifies that the debug heap should not be used.

-I[S]

Installs WinDbg as the postmortem debugger. For details, see [Enabling Postmortem Debugging](#).

After this action is attempted, a success or failure message is displayed. If **S** is included, this procedure is done silently if it is successful; only failure messages are displayed.

The **-I** parameter must not be used with any other parameters. This command will not actually start WinDbg, although a WinDbg window may appear for a moment.

-IA[S]

Associates WinDbg with the file extensions **.dmp**, **.mdmp**, and **.wew** in the registry. After this action is attempted, a success or failure message is displayed. If **S** is included, this procedure is done silently if it is successful; only failure messages are displayed. After this association is made, double-clicking a file with one of these extensions will start WinDbg.

The **-IA** parameter must not be used with any other parameters. This command will not actually start WinDbg, although a WinDbg window may appear for a moment.

-IU *KeyString*

Registers debugger remoting as an URL type so that users can auto-launch a debugger remote client with an URL. *KeyString* has the format `remdbgeng://RemotingOption`. *RemotingOption* is a string that defines the transport protocol as defined in the topic [Activating a Debugging Client](#). If this action succeeds, no message is displayed; if it fails, an error message is displayed.

The **-IU** parameter must not be used with any other parameters. Although a WinDbg window may appear for a moment, this command will not actually start WinDbg.

-i *ImagePath*

Specifies the location of the executables that generated the fault. If the path contains spaces, it should be enclosed in quotation marks.

-j

Allow journaling.

-k [*ConnectType*]

(Kernel mode only) Starts a kernel debugging session. For details, see [Live Kernel-Mode Debugging Using WinDbg](#). If **-k** is used without any *ConnectType* options following it, it must be the final entry on the command line.

-kl

(Windows XP and later, kernel mode only) Starts a kernel debugging session on the same machine as the debugger.

-kx *ExdiOptions*

(Kernel mode only) Starts a kernel debugging session using an EXDI driver. EXDI drivers are not described in this documentation. If you have an EXDI interface to your hardware probe or hardware simulator, please contact Microsoft for debugging information.

-log{o|a} *LogFile*

Begins logging information to a log file. If the specified log file already exists, it will be overwritten if **-logo** is used. If **loga** is used, the output will be appended to the file. For more details, see [Keeping a Log File in WinDbg](#).

-srcpath

Sets the local source path for a remote client. This option must follow **-remote** on the command line.

-n

Noisy symbol load: Enables verbose output from symbol handler. For details and for other methods of controlling this, see [SYMOPT_DEBUG](#).

-noinh

(User mode only) Prevents processes created by the debugger from inheriting handles from the debugger. For other methods of controlling this, see [Debugging a User-Mode Process Using WinDbg](#).

-noprio

Prevents any priority change. This parameter will prevent WinDbg from taking priority for CPU time while active.

-noshell

Prohibits all **.shell** commands. This prohibition will last as long as the debugger is running, even if a new debugging session is begun. For details, and for other ways to disable shell commands, see [Using Shell Commands](#).

-o

(User mode only) Debugs all processes launched by the target application (child processes). By default, processes created by the one you are debugging will run as they normally do.

-p PID

Specifies the decimal process ID to be debugged. This is used to debug a process that is already running.

-pb

(Windows XP and later, user mode only) Prevents the debugger from requesting an initial break-in when attaching to a target process. This can be useful if the application is already suspended, or if you wish to avoid creating a break-in thread in the target.

-pd

(Windows XP and later, user mode only) Causes the target application not to be terminated at the end of the debugging session. See [Ending a Debugging Session in WinDbg](#) for details.

-pe

(Windows XP and later, user mode only) Indicates that the target application is already being debugged. See [Re-attaching to the Target Application](#) for details.

-pn Name

Specifies the name of the process to be debugged. (This name must be unique.) This is used to debug a process that is already running.

-pr

(Windows XP and later, user mode only) Causes the debugger to start the target process running when it attaches to it. This can be useful if the application is already suspended and you wish it to resume execution.

-psn ServiceName

Specifies the name of a service contained in the process to be debugged. This is used to debug a process that is already running.

-pt Seconds

Specifies the break timeout, in seconds. The default is 30. See [Controlling the Target](#) for details.

-pv

(User mode only) Specifies that the debugger should attach to the target process noninvasively. For details, see [Noninvasive Debugging \(User Mode\)](#).

-Q

Suppresses the "Save Workspace?" dialog box. Workspaces are not automatically saved. See [Using Workspaces](#) for details.

-QS

Suppresses the "Reload Source?" dialog box. Source files are not automatically reloaded.

-QSY

Suppresses the "Reload Source?" dialog box and automatically reloads source files.

-QY

Suppresses the "Save Workspace?" dialog box and automatically saves workspaces. See [Using Workspaces](#) for details.

-robp

This allows CDB to set a breakpoint on a read-only memory page. (The default is for such an operation to fail.)

-sdce

Causes the debugger to display **File access error** messages during symbol load. For details and for other

methods of controlling this, see [SYMOPT_FAIL_CRITICAL_ERRORS](#).

-secure

Activates [Secure Mode](#).

-ses

Causes the debugger to perform a strict evaluation of all symbol files and ignore any questionable symbols. For details and for other methods of controlling this, see [SYMOPT_EXACT_SYMBOLS](#).

-sflags 0x Number

Sets all the symbol handler options at once. *Number* should be a hexadecimal number prefixed with **0x** -- a decimal without the **0x** is permitted, but the symbol options are binary flags and therefore hexadecimal is recommended. This option should be used with care, since it will override all the symbol handler defaults.

For details, see [Setting Symbol Options](#).

-sicv

Causes the symbol handler to ignore the CV record. For details and for other methods of controlling this, see [SYMOPT_IGNORE_CVREC](#).

-sins

Causes the debugger to ignore the symbol path and executable image path environment variables. For details, see [SYMOPT_IGNORE_NT_SYMPATH](#).

-snc

Causes the debugger to turn off C++ translation. For details and for other methods of controlling this, see [SYMOPT_NO_CPP](#).

-snul

Disables automatic symbol loading for unqualified names. For details and for other methods of controlling this, see [SYMOPT_NO_UNQUALIFIED_LOADS](#).

-srcpath SourcePath

Specifies the source file search path. Separate multiple paths with a semicolon (;). If the path contains spaces, it should be enclosed in quotation marks. For details, and for other ways to change this path, see [Source Path](#).

-sup

Causes the symbol handler to search the public symbol table during every symbol search. For details and for other methods of controlling this, see [SYMOPT_AUTO_PUBLICS](#).

-T Title

Sets WinDbg window title.

-v

Enables verbose output from debugger.

-W Workspace

Loads the given named workspace. If the workspace name contains spaces, enclose it in quotation marks. If no workspace of this name exists, you will be given the option of creating a new workspace with this name or abandoning the load attempt. For details, see [Using Workspaces](#).

-WF Filename

Loads the workspace from the given file. *Filename* should include the file and the extension (usually .wew). If the workspace name contains spaces, enclose it in quotation marks. If no workspace file with this name exists, you will be given the option of creating a new workspace file with this name or abandoning the load attempt. For details, see [Using Workspaces](#).

-WX

Disables automatic workspace loading. For details, see [Using Workspaces](#).

-y *SymbolPath*

Specifies the symbol search path. Separate multiple paths with a semicolon (;). If the path contains spaces, it should be enclosed in quotation marks. For details, and for other ways to change this path, see [Symbol Path](#).

-z *DumpFile*

Specifies the name of a crash dump file to debug. If the path and file name contain spaces, this must be surrounded by quotation marks. It is possible to open several dump files at once by including multiple **-z** options, each followed by a different *DumpFile* value. For details, see [Analyzing a User-Mode Dump File with WinDbg](#) or [Analyzing a Kernel-Mode Dump File with WinDbg](#).

-zp *PageFile*

Specifies the name of a modified page file. This is useful if you are debugging a dump file and want to use the [.pagein \(Page In Memory\)](#) command. You cannot use **-zp** with a standard Windows page file -- only specially-modified page files can be used.

executable

Specifies the command line of an executable process. This is used to launch a new process and debug it. This has to be the final item on the command line. All text after the executable name is passed to the executable as its argument string. For details, see [Debugging a User-Mode Process Using WinDbg](#).

-?

Pops up this HTML Help window.

When you are running the debugger from the command line, specify arguments for the target application after application's file name. For instance:

```
windbg myexe arg1 arg2
```

[Send comments about this topic to Microsoft](#)

DbgSrv Command-Line Options

5/31/2017 • 2 min to read • [Edit Online](#)

The DbgSrv command line uses the following syntax.

```
dbgsrv -t ServerTransport [-sifeo image.ext] -c[s] AppCmdLine [-x | -pc]  
dbgsrv -?
```

All options are case-sensitive.

Parameters

-t *ServerTransport*

Specifies the transport protocol. For a list of the possible protocols and the syntax for *ServerTransport* in each case, see [Activating a Process Server](#).

-sifeo *Executable*

Suspends the Image File Execution Option (IFEO) value for the given image. *Executable* should include the file name of the executable image, including the file name extensions. The -sifeo option allows DbgSrv to be set as the IFEO debugger for an image created by the -c option, without causing recursive invocation due to the IFEO setting. This option can be used only if -c is used.

-c

Causes DbgSrv to create a new process. You can use this to create a process that you intend to debug. This is similar to spawning a new process from the debugger, except that this process will *not* be debugged when it is created. To debug this process, determine its PID and use the **-p** option when starting the smart client to debug this process.

s

Causes the newly-created process to be immediately suspended. If you are using this option, it is recommended that you use CDB as your smart client, and that you start the smart client with the **-pb** command-line option, in conjunction with **-p** PID. If you include the **-pb** option on the command line, the process will resume when the debugger attaches to it; otherwise you can resume the process with the [~*m](#) command.

AppCmdLine

Specifies the full command line of the process to be created. *AppCmdLine* can be either a Unicode or ASCII string, and can include any printable character. All text that appears after the **-c[s]** parameter will be taken to form the string *AppCmdLine*.

-x

Causes the remainder of the command line to be ignored. This option is useful if you are launching DbgSrv from an application that may append unwanted text to its command line.

-pc

Causes the remainder of the command line to be ignored. This option is useful if you are launching DbgSrv from an application that may append unwanted text to its command line. A syntax error results if -pc is the final element on the DbgSrv command line. Aside from this restriction, -pc is identical to -x.

-?

Displays a message box with help text for the DbgSrv command line.

For information about using DbgSrv, see [Process Servers \(User Mode\)](#).

[Send comments about this topic to Microsoft](#)

KdSrv Command-Line Options

5/31/2017 • 1 min to read • [Edit Online](#)

The KdSrv command line uses the following syntax.

```
kdsrv -t ServerTransport
```

Parameters

-t *ServerTransport*

Specifies the transport protocol. For a list of the possible protocols and the syntax for *ServerTransport* in each case, see [Activating a KD Connection Server](#).

If you type **kdsrv** with no parameters, a message box with help text appears.

For information about using KdSrv, see [KD Connection Servers \(Kernel Mode\)](#).

[Send comments about this topic to Microsoft](#)

DbEngPrx Command-Line Options

5/31/2017 • 1 min to read • [Edit Online](#)

The DbEngPrx command line uses the following syntax.

```
dbengprx [-p] -c ClientTransport -s ServerTransport  
dbengprx -?
```

Parameters

-p

Causes DbEngPrx to continue existing even after all connections to it are dropped.

-c *ClientTransport*

Specifies the protocol settings to be used in connecting to the server. The protocol should match that used when the server was created. For details, see [Activating a Repeater](#).

-s *ServerTransport*

Specifies the protocol settings that will be used when the client connects to the repeater. For details, see

[Activating a Repeater](#).

-?

Displays a message box with help text for the DbEngPrx command line.

For information about using DbEngPrx, see [Repeaters](#).

[Send comments about this topic to Microsoft](#)

KDbgCtrl Command-Line Options

5/31/2017 • 1 min to read • [Edit Online](#)

The KDbgCtrl command line uses the following syntax:

```
kdbgctrl [-e|-d|-c] [-ea|-da|-ca] [-eu|-du|-cu] [-eb|-db|-cb] [-sdb Size | -cdb]  
kdbgctrl -cx  
kdbgctrl -td ProcessID File  
kdbgctrl -?
```

Parameters

-e

Enables Full Kernel Debugging.

-d

Disables Full Kernel Debugging.

-c

Checks whether Full Kernel Debugging is enabled. Displays true if Full Kernel Debugging is enabled, and displays false if Full Kernel Debugging is disabled.

-ea

Enables Automatic Kernel Debugging.

-da

Disables Automatic Kernel Debugging.

-ca

Checks whether Automatic Kernel Debugging is enabled. Displays true if Automatic Kernel Debugging is enabled, and displays false if Automatic Kernel Debugging is disabled.

-eu

Enables User-Mode Error Handling.

-du

Disables User-Mode Error Handling.

-cu

Checks whether User-Mode Error Handling is enabled. Displays true if User-Mode Error Handling is enabled, and displays false if User-Mode Error Handling is disabled.

-eb

Enables blocking of kernel debugging.

-db

Disables blocking of kernel debugging.

-cb

Checks whether kernel debugging is blocked. Displays true if kernel debugging is blocked, and displays false if kernel debugging is not blocked.

-sdb *Size*

Sets the size of the DbgPrint buffer. If *Size* is prefixed with **0x** it will be interpreted as a hexadecimal number. If it is prefixed with **0** (zero), it will be interpreted as octal. Otherwise, it will be interpreted as decimal.

-cdb

Displays the current size, in bytes, of the DbgPrint buffer.

-cx

Determines the current Full Kernel Debugging setting and returns an appropriate value. This option cannot be combined with other options, and it does not display any output. It is designed for use in a batch file where the return value of the KDbgCtrl program can be tested. Possible return values are as follows:

VALUE	MEANING
0x10001	Full Kernel Debugging is enabled.
0x10002	Full Kernel Debugging is disabled.
Any other value	An error occurred. KDbgCtrl was unable to determine the current status of Full Kernel Debugging.

-td *ProcessID* *File*

Obtains a kernel triage dump file. Enter the process ID and a name for the dump file.

-?

Displays command-line help for KDbgCtrl.

Additional Information

For a description of all the KDbgCtrl settings, see [Using KDbgCtrl](#).

[Send comments about this topic to Microsoft](#)

DbgRpc Command-Line Options

5/31/2017 • 2 min to read • [Edit Online](#)

The DbgRpc command line must always contain exactly one of the **-l**, **-e**, **-t**, **-c**, or **-a** switches. The options following these switches depend on the switch used. The **-s**, **-p**, and **-r** options can be used with any other options.

```
dbgRPC [-s Server -p ProtSeq] [-r Radix] -l -P ProcessID -L CellID1.CellID2

dbgRPC [-s Server -p ProtSeq] [-r Radix] -e [-E EndpointName]

dbgRPC [-s Server -p ProtSeq] [-r Radix] -t -P ProcessID [-T ThreadID]

dbgRPC [-s Server -p ProtSeq] [-r Radix] [-c|-a] [-C CallID] [-I IfStart] [-N ProcNum] [-P ProcessID]

dbgRPC -?
```

Parameters

-s *Server*

Allows DbgRpc to view information from a remote machine. The server name should not be preceded by slash marks. For more information about using DbgRpc remotely, see [Using the DbgRpc Tool](#).

-p *ProtSeq*

Specifies the remote transport to be used. The possible values of *ProtSeq* are **ncacn_ip_tcp** (TCP protocol) and **ncacn_np** (named pipe protocol). TCP protocol is recommended. For more information about using DbgRpc remotely, see [Using the DbgRpc Tool](#).

-r *Radix*

Specifies the radix to be used for the command parameters. The default is base 16. If the **-r** parameter is used, it should be placed first on the line, since it only affects parameters listed after itself. It does not affect the output of the DbgRpc tool.

-l

Displays RPC state information for the specified cell. For an example, see [Get RPC Cell Information](#).

ProcessID

Specifies the process ID (PID) of a process. When the **-l** option is being used, this should be the process whose server contains the desired cell. When the **-t** option is being used, this should be the process containing the desired thread. When the **-c** or **-a** options are being used, this parameter is optional; it should be the server process that owns the calls you wish to display.

CellID1.CellID2

Specifies the number of the cell to be displayed.

-e

Searches the system's RPC state information for endpoint information. For an example, see [Get RPC Endpoint Information](#).

EndpointName

Specifies the number of the endpoint to be displayed. If omitted, the endpoints for all processes on the system are displayed.

-t

Searches the system's RPC state information for thread information. For an example, see [Get RPC Thread Information](#).

ThreadID

Specifies the thread ID of the thread to be displayed. If omitted, all threads in the specified process will be displayed.

-c

Searches the system's RPC state information for server-side call (SCALL) information. For an example, see [Get RPC Call Information](#).

-a

Searches the system's RPC state information for client call (CCALL) information. For an example, see [Get RPC Client Call Information](#). This option requires full RPC state information.

CallID

Specifies the call ID. This parameter is optional; include it only if you want to display calls matching a specific *CallID* value.

IfStart

Specifies the first DWORD of the interface's universally unique identifier (UUID) on which the call was made. This parameter is optional; include it only if you want to display calls matching a specific *IfStart* value.

ProcNum

Specifies the procedure number of this call. (The RPC Run-Time identifies individual routines from an interface by numbering them by position in the IDL file -- the first routine in the interface is 0, the second 1, and so on.) This parameter is optional; include it only if you want to display calls matching a specific *ProcNum* value.

Additional Information

For more information about debugging Microsoft Remote Procedure Call (RPC), see [RPC Debugging](#).

[Send comments about this topic to Microsoft](#)

SymStore Command-Line Options

5/31/2017 • 3 min to read • [Edit Online](#)

The following syntax forms are supported for SymStore transactions. The first parameter must always be **add** or **del**. The order of the other parameters is immaterial.

```
symstore add [/r] [/p [/1] [-:MSG Message] [-:REL] [-:NOREFS]] /f File /s Store /t Product [/v Version] [/o] [/c Comment] [/dLogFile] [/compress]

symstore add [/r] [/p [/1] [-:REL] [-:NOREFS]] /g Share /f File /x IndexFile [/a] [/o] [/dLogFile]

symstore add /y IndexFile /g Share /s Store [/p [-:MSG Message] [-:REL] [-:NOREFS]] /t Product [/v Version] [/o] [/c Comment] [/dLogFile] [/compress]

symstore query [/r] /f File /s Store [/o] [/dLogFile]

symstore del /i ID /s Store [/o] [/dLogFile]

symstore /?
```

Parameters

/f *File*

Specifies the network path of files or directories to add.

/g *Share*

Specifies the server and share where the symbol files were originally stored. When used with **/f**, *Share* should be identical to the beginning of the *File* specifier. When used with **/y**, *Share* should be the location of the original symbol files (not the index file). This allows you to later change this portion of the file path in case you move the symbol files to a different server and share.

/s *Store*

Specifies the root directory for the symbol store.

/m *Prefix*

Causes SymStore to prefer using symbols from paths beginning with *Prefix* when storing files or updating pointers. This option cannot be used with the **/x** option.

/h { **PUB** | **PRI** }

Causes SymStore to prefer using public symbols (if PUB is specified), or private symbols (if PRI is specified) when storing or updating symbols. This option has no effect on binary files.

/i *ID*

Specifies the transaction ID string.

/p

Causes SymStore to store a pointer to the file, rather than the file itself.

/l

Allows the file specified by *File* to be in a local directory rather than a network path. (This option can only be used when both **/f** and **/p** are used.)

-:MSG *Message*

Adds the specified *Message* to each file. (This option can only be used when **/p** is used.)

-:REL

Allows the paths in the file pointers to be relative. This option implies the **/I** option. (This option can only be used when **/p** is used.)

-:NOREFS

Omits the creation of reference pointer files for the files and pointers being stored. This option is only valid during the initial creation of a symbol store if the store being changed was created with this option.

/r

Causes SymStore to add files or directories recursively.

/t Product

Specifies the name of the product.

/v Version

Specifies the version of the product.

/c Comment

Specifies a comment for the transaction.

/dLogFile

Specifies a log file to be used for command output. If this is not included, transaction information and other output is sent to **stdout**.

/o

Causes SymStore to display verbose output.

/x IndexFile

Causes SymStore not to store the actual symbol files. Instead, SymStore records information in the *IndexFile* that will enable SymStore to access the symbol files at a later time.

/a

Causes SymStore to append new indexing information to an existing index file. (This option is only used with the **/x** option.)

/y IndexFile

Causes SymStore to read the data from a file created with **/x**.

/yi IndexFile

Appends a comment with the transaction ID to the end of an index file created with the **/x** option.

/z { PUB | PRI }

Causes SymStore to index only the type of symbols specified. If **PUB** is specified, then only the symbols that have had the full source information stripped will be indexed. If **PRI** is specified, then only the symbols that contain the full source information will be indexed. SymStore will always index binary symbols.

/compress

Causes SymStore to create a compressed version of each file copied to the symbol store instead of using an uncompressed copy of the file. This option is only valid when storing files and not pointers, and consequently cannot be used when the **/p** option is used.

/?

Displays help text for the SymStore command.

Additional Information

For more information about SymStore, see [Using Symbol Servers and Symbol Stores](#).

Environment Variables

5/26/2017 • 1 min to read • [Edit Online](#)

This reference section includes:

[General Environment Variables](#)

[Kernel-Mode Environment Variables](#)

For information about using environment variables for debugging, see [Getting Set Up for Debugging](#).

[Send comments about this topic to Microsoft](#)

General Environment Variables

6/1/2017 • 2 min to read • [Edit Online](#)

The following table lists the environment variables that can be used in both user-mode and kernel-mode debugging.

VARIABLE	MEANING
<code>_NT_DEBUGGER_EXTENSION_PATH = Path</code>	Specifies the path that the debugger will first search for extension DLLs. <i>Path</i> can contain a drive letter followed by a colon (:). Separate multiple directories with semicolons (;). For details, see Loading Debugger Extension DLLs .
<code>_NT_EXECUTABLE_IMAGE_PATH = Path</code>	Specifies the path containing the binary executable files. <i>Path</i> can contain a drive letter followed by a colon (:). Separate multiple directories with semicolons (;).
<code>_NT_SOURCE_PATH = Path</code>	Specifies the path containing the source files for the target. <i>Path</i> can contain a drive letter followed by a colon (:). Separate multiple directories with semicolons (;). For details, and for other ways to change this path, see Source Path .
<code>_NT_SYMBOL_PATH = Path</code>	Specifies the root of a directory tree containing the symbol files. <i>Path</i> can contain a drive letter followed by a colon (:). Separate multiple directories with semicolons (;). For details, and for other ways to change this path, see Symbol Path .
<code>_NT_ALT_SYMBOL_PATH = Path</code>	Specifies an alternate symbol path searched before <code>_NT_SYMBOL_PATH</code> . This is useful for keeping private versions of symbol files. <i>Path</i> can contain a drive letter followed by a colon (:). Separate multiple directories with semicolons (;). For details, see Symbol Path .
<code>_NT_SYMBOL_PROXY = Proxy:Port</code>	Specifies the proxy server to be used by SymSrv. For details, see Firewalls and Proxy Servers .
<code>_NT_DEBUG_HISTORY_SIZE = Number</code>	Specifies the number of commands in the command history that can be accessed during remote debugging. Because commands vary in length, the number of lines available may not exactly match <i>Number</i> . For details, and for other ways to change this number, see Using Debugger Commands .
<code>_NT_DEBUG_LOG_FILE_OPEN = Filename</code>	(CDB and KD only) Specifies the log file to which the debugger should send output.

VARIABLE	MEANING
_NT_DEBUG_LOG_FILE_APPEND = <i>Filename</i>	(CDB and KD only) Specifies the log file to which the debugger should append output.
_NT_EXPR_EVAL = { masm c++ }	Specifies the default expression evaluator. If masm is specified, MASM expression syntax will be used. If c++ is specified, C++ expression syntax will be used. MASM expression syntax is the default. See Evaluating Expressions for details.
_NO_DEBUG_HEAP	(Windows XP and later) Specifies that the debug heap should not be used for user-mode debugging.
DBGENG_NO_DEBUG_PRIVILEGE	Prevents processes spawned by the debugger from inheriting SeDebugPrivilege.
DBGENG_NO_BUGCHECK_ANALYSIS	Prevents automated bugcheck analysis.
DBGHELP_HOMEDIR	Specifies the path for the root of the default downstream store used by SymSrv and SrcSrv. <i>Path</i> can contain a drive letter followed by a colon (:). Separate multiple directories with semicolons (;).
SRCsrv_INI_FILE	Specifies the path and name of the configuration file used by SrcSrv . By default, the path is the srcsrv subdirectory of the Debugging Tools for Windows installation directory, and the file name is Srcsrv.ini. See Source Indexing for details.

[Send comments about this topic to Microsoft](#)

Kernel-Mode Environment Variables

5/26/2017 • 1 min to read • [Edit Online](#)

The following table lists the environment variables that are used only in kernel-mode debugging.

VARIABLE	MEANING
<code>_NT_DEBUG_PORT = ComPort</code>	Specifies the COM port to be used in a kernel connection. For details, see Getting Set Up for Debugging .
<code>_NT_DEBUG_BAUD_RATE = BaudRate</code>	Specifies the baud rate to be used over the COM port connection.
<code>_NT_DEBUG_BUS = 1394</code>	Specifies that kernel debugging will be done over a 1394 cable connection.
<code>_NT_DEBUG_1394_CHANNEL = 1394Channel</code>	Specifies the channel to be used for the 1394 kernel connection.
<code>_NT_DEBUG_1394_SYMLINK = Protocol</code>	Specifies the connection protocol to be used for the 1394 kernel connection.
<code>KDQUIET =Anything</code>	If KDQUIET is defined, the debugger will run in <i>quiet mode</i> . Quiet mode involves three distinct effects: <ol style="list-style-type: none">1. The debugger does not display messages each time an extension DLL is loaded or unloaded.2. The r (Registers) command no longer requires an equal sign in its syntax.3. The debugger will not display a warning message when breaking into the target computer. Quiet mode can also be controlled by using the sq (Set Quiet Mode) command.
<code>_NT_DEBUG_CACHE_SIZE = Size</code>	Specifies the maximum kernel debugging cache size, in bytes. This cache holds data received by the host computer from the serial connection. The default is 1,024,000.

VARIABLE	MEANING
_NT_DEBUG_OPTIONS = <i>Option</i>	<p>Specifies one of the following two values:</p> <p>NOEXTWARNING tells the debugger not to output a warning when it cannot find an extension command.</p> <p>NOVERSIONCHECK tells the debugger not to check the version of debugger extensions.</p> <p>These options can be modified or displayed by using the so (Set Kernel Options) command.</p>
_NT_KD_FILES = <i>MapFile</i>	<p>Specifies a driver replacement map file. For details and for other methods of controlling driver replacement, see Mapping Driver Files.</p>

Debugger Commands

5/26/2017 • 1 min to read • [Edit Online](#)

This section includes the following topics:

[Syntax Rules](#)

[Command Tokens](#)

[Commands](#)

[Meta-Commands](#)

[Control Keys](#)

[Send comments about this topic to Microsoft](#)

Syntax Rules

5/31/2017 • 1 min to read • [Edit Online](#)

This section describes the syntax rules that you must follow to use debugger commands.

When you are debugging, you should obey the following general syntax rules:

- You can use any combination of uppercase and lowercase letters in commands and arguments, except when specifically noted in the topics in this section.
- You can separate multiple command parameters by one or more spaces or by a comma (,).
- You can typically omit the space between a command and its first parameter . You can frequently omit other spaces if this omission does not cause any ambiguity.

The command reference topics in this section use the following items:

- Characters in **bold** font style indicate items that you must literally type.
- Characters in *italic* font style indicate parameters that are explained in the "Parameters" section of the reference topic.
- Parameters in brackets ([xxx]) are optional. Brackets with a vertical bar ([xxx|yyy]) indicate that you can use one, or none, of the enclosed parameters.
- Braces with vertical bars ({xxx|yyy}) indicate that you must use exactly one of the enclosed parameters .

The following topics describe the syntax that the following parameter types use:

[Numerical Expression Syntax](#)

[String Wildcard Syntax](#)

[Register Syntax](#)

[Pseudo-Register Syntax](#)

[Source Line Syntax](#)

[Address and Address Range Syntax](#)

[Thread Syntax](#)

[Process Syntax](#)

[System Syntax](#)

[Multiprocessor Syntax](#)

Syntax also plays an important role in using symbols. For further details, see [Symbol Syntax and Symbol Matching](#).

[Send comments about this topic to Microsoft](#)

Numerical Expression Syntax

5/26/2017 • 1 min to read • [Edit Online](#)

The debugger accepts two different kinds of numeric expressions: *C++ expressions* and *MASM expressions*. Each of these expressions follows its own syntax rules for input and output.

For more information about when each syntax type is used, see [Evaluating Expressions](#).

This section includes the following topics:

[MASM Numbers and Operators](#)

[C++ Numbers and Operators](#)

[MASM Expressions vs. C++ Expressions](#)

[Expression Examples](#)

[Sign Extension](#)

[Send comments about this topic to Microsoft](#)

MASM Numbers and Operators

5/26/2017 • 7 min to read • [Edit Online](#)

Before version 4.0 of the Debugging Tools for Windows package, NTSD, CDB, KD, and WinDbg used only Microsoft Macro Assembler (MASM) expression syntax.

Numbers in MASM Expressions

You can put numbers in MASM expressions in base 16, 10, 8, or 2.

Use the [n \(Set Number Base\)](#) command to set the default radix to 16, 10, or 8. All unprefixed numbers are then interpreted in this base. You can override the default radix by specifying the **0x** prefix (hexadecimal), the **0n** prefix (decimal), the **0t** prefix (octal), or the **0y** prefix (binary).

You can also specify hexadecimal numbers by adding an **h** after the number. You can use uppercase or lowercase letters within numbers. For example, "0x4AB3", "0X4aB3", "4AB3h", "4ab3h", and "4aB3H" have the same meaning.

If you do not add a number after the prefix in an expression, the number is read as 0. Therefore, you can write 0 as 0, the prefix followed by 0, and only the prefix. For example, in hexadecimal, "0", "0x0", and "0x" have the same meaning.

You can enter hexadecimal 64-bit values in the **xxxxxxxx`xxxxxxxx** format. You can also omit the grave accent (`). If you include the grave accent, [automatic sign extension](#) is disabled.

Symbols in MASM Expressions

In MASM expressions, the numeric value of any symbol is its memory address. Depending on what the symbol refers to, this address is the address of a global variable, local variable, function, segment, module, or any other recognized label.

To specify which module the address is associated with, include the module name and an exclamation point (!) before the name of the symbol. If the symbol could be interpreted as a hexadecimal number, include the module name and an exclamation point, or just an exclamation point, before the symbol name. For more information about symbol recognition, see [Symbol Syntax and Symbol Matching](#).

Use two colons (::) or two underscores (_) to indicate the members of a class.

Use a grave accent (`) or an apostrophe (') in a symbol name only if you add a module name and exclamation point before the symbol.

Numeric Operators in MASM Expressions

You can modify any component of an expression by using a unary operator. You can combine any two components by using a binary operator. Unary operators take precedence over binary operators. When you use multiple binary operators, the operators follow the fixed precedence rules that are described in the following tables.

You can always use parentheses to override precedence rules.

If part of an MASM expression is enclosed in parentheses and two at signs (@@) appear before the expression, the expression is interpreted according to [C++ expression rules](#). You cannot add a space between the two at signs and the opening parenthesis. You can also specify the [expression evaluator](#) by using **@@c++(...)** or **@@masm(...)**.

When you perform arithmetic computations, the MASM expression evaluator treats all numbers and symbols as

ULONG64 types.

Unary address operators assume DS as the default segment for addresses. Expressions are evaluated in order of operator precedence. If adjacent operators have equal precedence, the expression is evaluated from left to right.

You can use the following unary operators.

OPERATOR	MEANING
+	Unary plus
-	Unary minus
not	Returns 1 if the argument is zero. Returns zero for any nonzero argument.
hi	High 16 bits
low	Low 16 bits
by	Low-order byte from the specified address.
\$pby	Same as by except that it takes a physical address. Only physical memory that uses the default caching behavior can be read.
wo	Low-order word from the specified address.
\$pwo	Same as wo except that it takes a physical address. Only physical memory that uses the default caching behavior can be read.
dwo	Double-word from the specified address.
\$pdwo	Same as dwo except that it takes a physical address. Only physical memory that uses the default caching behavior can be read.
qwo	Quad-word from the specified address.
\$pqwo	Same as qwo except that it takes a physical address. Only physical memory that uses the default caching behavior can be read.

OPERATOR	MEANING
poi	Pointer-sized data from the specified address. The pointer size is 32 bits or 64 bits. In kernel debugging, this size is based on the processor of the <i>target</i> computer. In user-mode debugging on an Itanium-based computer, this size is 32 bits or 64 bits, depending on the target application. Therefore, poi is the best operator to use if you want pointer-sized data.
\$ppoi	Same as poi except that it takes a physical address. Only physical memory that uses the default caching behavior can be read.

You can use the following binary operators. The operators in each cell take precedence over those in lower cells. Operators in the same cell are of the same precedence and are parsed from left to right.

OPERATOR	MEANING
*	Multiplication
/	Integer division
mod (or %)	Modulus (remainder)
+	Addition
-	Subtraction
<<	Left shift
>>	Logical right shift
>>>	Arithmetic right shift
= (or ==)	Equal to
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
!=	Not equal to
and (or &)	Bitwise AND
xor (or ^)	Bitwise XOR (exclusive OR)
or (or)	Bitwise OR

The <, >, =, ==, and != comparison operators evaluate to 1 if the expression is true or zero if the expression is false. A single equal sign (=) is the same as a double equal sign (==). You cannot use side effects or assignments

within a MASM expression.

An invalid operation (such as division by zero) results in an "Operand error" is returned to the [Debugger Command window](#).

Non-Numeric Operators in MASM Expressions

You can also use the following additional operators in MASM expressions.

OPERATOR	MEANING
\$fnsucc (<i>FnAddress</i> , <i>RetVal</i> , <i>Flag</i>)	Interprets the <i>RetVal</i> value as a return value for the function that is located at the <i>FnAddress</i> address. If this return value qualifies as a success code, \$fnsucc returns TRUE . Otherwise, \$fnsucc returns FALSE . If the return type is BOOL, bool, HANDLE, HRESULT, or NTSTATUS, \$fnsucc correctly understands whether the specified return value qualifies as a success code. If the return type is a pointer, all values other than NULL qualify as success codes. For any other type, success is defined by the value of <i>Flag</i> . If <i>Flag</i> is 0, a nonzero value of <i>RetVal</i> is success. If <i>Flag</i> is 1, a zero value of <i>RetVal</i> is success.
\$iment (<i>Address</i>)	Returns the address of the image entry point in the loaded module list. <i>Address</i> specifies the Portable Executable (PE) image base address. The entry is found by looking up the image entry point in the PE image header of the image that <i>Address</i> specifies. You can use this function for both modules that are already in the module list and to set unresolved breakpoints by using the bu command.
\$scmp (" <i>String1</i> ", " <i>String2</i> ")	Evaluates to -1, 0, or 1, like the strcmp C function.
\$sicmp (" <i>String1</i> ", " <i>String2</i> ")	Evaluates to -1, 0, or 1, like the strcmp Microsoft Win32 function .
\$spat (" <i>String</i> ", " <i>Pattern</i> ")	Evaluates to TRUE or FALSE depending on whether <i>String</i> matches <i>Pattern</i> . The matching is case-insensitive. <i>Pattern</i> can contain a variety of wildcard characters and specifiers. For more information about the syntax, see String Wildcard Syntax .
\$vvalid (<i>Address</i> , <i>Length</i>)	Determines whether the memory range that begins at <i>Address</i> and extends for <i>Length</i> bytes is valid. If the memory is valid, \$vvalid evaluates to 1. If the memory is invalid, \$vvalid evaluates to 0.

Registers and Pseudo-Registers in MASM Expressions

You can use registers and pseudo-registers within MASM expressions. You can add an at sign (@) before all registers and pseudo-registers. The at sign causes the debugger to access the value more quickly. This at sign is unnecessary for the most common x86-based registers. For other registers and pseudo-registers, we recommend that you add the at sign, but it is not actually required. If you omit the at sign for the less common registers, the

debugger tries to parse the text as a hexadecimal number, then as a symbol, and finally as a register.

You can also use a period (.) to indicate the current instruction pointer. You should not add an at sign before this period, and you cannot use a period as the first parameter of the **r command**. This period has the same meaning as the **\$ip** pseudo-register.

For more information about registers and pseudo-registers, see [Register Syntax](#) and [Pseudo-Register Syntax](#).

Source Line Numbers in MASM Expressions

You can use source file and line number expressions within MASM expressions. You must enclose these expressions by using grave accents (`). For more information about the syntax, see [Source Line Syntax](#).

[Send comments about this topic to Microsoft](#)

C++ Numbers and Operators

5/26/2017 • 6 min to read • [Edit Online](#)

The C++ expression parser supports all forms of C++ expression syntax. The syntax includes all data types (including pointers, floating-point numbers, and arrays) and all C++ unary and binary operators.

Numbers in C++ Expressions

Numbers in C++ expressions are interpreted as decimal numbers, unless you specify them in another manner. To specify a hexadecimal integer, add **0x** before the number. To specify an octal integer, add **0** (zero) before the number.

The default debugger radix does not affect how you enter C++ expressions. You cannot directly enter a binary number (except by nesting a MASM expression within the C++ expression).

You can enter a hexadecimal 64-bit value in the `xxxxxxxx`xxxxxxxx` format. (You can also omit the grave accent (`).) Both formats produce the same value.

You can use the **L**, **U**, and **I64** suffixes with integer values. The actual size of the number that is created depends on the suffix and the number that you enter. For more information about this interpretation, see a C++ language reference.

The *output* of the C++ expression evaluator keeps the data type that the C++ expression rules specify. However, if you use this expression as an argument for a command, a cast is always made. For example, you do not have to cast integer values to pointers when they are used as addresses in command arguments. If the expression's value cannot be validly cast to an integer or a pointer, a syntax error occurs.

You can use the **0n** (decimal) prefix for some *output*, but you cannot use it for C++ expression input.

Characters and Strings in C++ Expressions

You can enter a character by surrounding it with single quotation marks ('). The standard C++ escape characters are permitted.

You can enter string literals by surrounding them with double quotation marks ("). You can use \" as an escape sequence within such a string. However, strings have no meaning to the [expression evaluator](#).

Symbols in C++ Expressions

In a C++ expression, each symbol is interpreted according to its type. Depending on what the symbol refers to, it might be interpreted as an integer, a data structure, a function pointer, or any other data type. If you use a symbol that does not correspond to a C++ data type (such as an unmodified module name) within a C++ expression, a syntax error occurs.

If the symbol might be ambiguous, you can add a module name and an exclamation point (!) or only an exclamation point before the symbol. For more information about symbol recognition, see [Symbol Syntax and Symbol Matching](#).

You can use a grave accent (`) or an apostrophe (') in a symbol name only if you add a module name and exclamation point before the symbol name.

When you add the < and > delimiters after a template name, you can add spaces between these delimiters.

Operators in C++ Expressions

You can always use parentheses to override precedence rules.

If you enclose part of a C++ expression in parentheses and add two at signs (@@) before the expression, the

expression is interpreted according to MASM expression rules. You cannot add a space between the two at signs and the opening parenthesis. The final value of this expression is passed to the C++ expression evaluator as a ULONG64 value. You can also specify the expression evaluator by using **@@c++(...)** or **@@masm(...)**.

Data types are indicated as usual in the C++ language. The symbols that indicate arrays (**[]**), pointer members (**->**), UDT members (**.**), and members of classes (**::**) are all recognized. All arithmetic operators are supported, including assignment and side-effect operators. However, you cannot use the **new**, **delete**, and **throw** operators, and you cannot actually call a function.

Pointer arithmetic is supported and offsets are scaled correctly. Note that you cannot add an offset to a function pointer. (If you have to add an offset to a function pointer, cast the offset to a character pointer first.)

As in C++, if you use operators with invalid data types, a syntax error occurs. The debugger's C++ expression parser uses slightly more relaxed rules than most C++ compilers, but all major rules are enforced. For example, you cannot shift a non-integer value.

You can use the following operators. The operators in each cell take precedence over those in lower cells. Operators in the same cell are of the same precedence and are parsed from left to right. As with C++, expression evaluation ends when its value is known. This ending enables you to effectively use expressions such as **?? myPtr** **&& *myPtr**.

OPERATOR	MEANING
<i>Expression // Comment</i>	Ignore all subsequent text
<i>Class :: Member</i>	Member of class
<i>Class ::~Member</i>	Member of class (destructor)
:: Name	Global
<i>Structure . Field</i>	Field in a structure
<i>Pointer -> Field</i>	Field in referenced structure
<i>Name [integer]</i>	Array subscript
<i>LValue ++</i>	Increment (after evaluation)
<i>LValue --</i>	Decrement (after evaluation)
dynamic_cast <type>(Value)	Typecast (always performed)
static_cast <type>(Value)	Typecast (always performed)
reinterpret_cast <type>(Value)	Typecast (always performed)
const_cast <type>(Value)	Typecast (always performed)

OPERATOR	MEANING
<code>(type) Value</code>	Typecast (always performed)
<code>sizeof value</code>	Size of expression
<code>sizeof(type)</code>	Size of data type
<code>++ LValue</code>	Increment (before evaluation)
<code>-- LValue</code>	Decrement (before evaluation)
<code>~ Value</code>	Bit complement
<code>! Value</code>	Not (Boolean)
<code>Value</code>	Unary minus
<code>+ Value</code>	Unary plus
<code>& LValue</code>	Address of data type
<code>Value</code>	Dereference
<code>Structure . * Pointer</code>	Pointer to member of structure
<code>Pointer -> * Pointer</code>	Pointer to member of referenced structure
<code>Value Value</code>	Multiplication
<code>Value / Value</code>	Division
<code>Value % Value</code>	Modulus
<code>Value + Value</code>	Addition
<code>Value - Value</code>	Subtraction
<code>Value << Value</code>	Bitwise shift left
<code>Value >> Value</code>	Bitwise shift right
<code>Value < Value</code>	Less than (comparison)
<code>Value <= Value</code>	Less than or equal (comparison)
<code>Value > Value</code>	Greater than (comparison)
<code>Value >= Value</code>	Greater than or equal (comparison)
<code>Value == Value</code>	Equal (comparison)
<code>Value != Value</code>	Not equal (comparison)
<code>Value & Value</code>	Bitwise AND
<code>Value ^ Value</code>	Bitwise XOR (exclusive OR)
<code>Value Value</code>	Bitwise OR

OPERATOR	MEANING
<i>Value && Value</i>	Logical AND
<i>Value Value</i>	Logical OR
<i>LValue = Value</i>	Assign
<i>LValue *= Value</i>	Multiply and assign
<i>LValue /= Value</i>	Divide and assign
<i>LValue %= Value</i>	Modulo and assign
<i>LValue += Value</i>	Add and assign
<i>LValue -= Value</i>	Subtract and assign
<i>LValue <= Value</i>	Shift left and assign
<i>LValue >= Value</i>	Shift right and assign
<i>LValue &= Value</i>	AND and assign
<i>LValue = Value</i>	OR and assign
<i>LValue ^= Value</i>	XOR and assign
<i>Value ? Value : Value</i>	Conditional evaluation
<i>Value , Value</i>	Evaluate all values, and then discard all except the rightmost value

Registers and Pseudo-Registers in C++ Expressions

You can use registers and pseudo-registers within C++ expressions. You must add an at sign (@) before the register or pseudo-register.

The expression evaluator automatically performs the proper cast. Actual registers and integer-value pseudo-registers are cast to ULONG64. All addresses are cast to PUCHAR, **\$thread** is cast to ETHREAD*, **\$proc** is cast to EPROCESS*, **\$teb** is cast to TEB*, and **\$peb** is cast to PEB*.

You cannot change a register or pseudo-register by an assignment or side-effect operator. You must use the **r (Registers)** command to change these values.

For more information about registers and pseudo-registers, see [Register Syntax](#) and [Pseudo-Register Syntax](#).

Macros in C++ Expressions

You can use macros within C++ expressions. You must add a number sign (#) before the macros.

You can use the following macros. These macros have the same definitions as the Microsoft Windows macros with the same name. (The Windows macros are defined in Winnt.h.)

MACRO	RETURN VALUE
<code>#CONTAINING_RECORD(Address, Type, Field)</code>	Returns the base address of an instance of a structure, given the type of the structure and the address of a field within the structure.

MACRO	RETURN VALUE
#FIELD_OFFSET(<i>Type, Field</i>)	Returns the byte offset of a named field in a known structure type.
#RTL_CONTAINS_FIELD (<i>Struct, Size, Field</i>)	Indicates whether the given byte size includes the desired field.
#RTL_FIELD_SIZE(<i>Type, Field</i>)	Returns the size of a field in a structure of known type, without requiring the type of the field.
#RTL_NUMBER_OF(<i>Array</i>)	Returns the number of elements in a statically sized array.
#RTL_SIZEOF_THROUGH_FIELD(<i>Type, Field</i>)	Returns the size of a structure of known type, up through and including a specified field.

MASM Expressions vs. C++ Expressions

5/26/2017 • 1 min to read • [Edit Online](#)

The most significant differences between MASM expression evaluation and C++ expression evaluation are as follows:

- In an MASM expression, the numeric value of any symbol is its memory address. In a C++ expression, the numeric value of a variable is its actual value, not its address. Data structures do not have numeric values. Instead, they are treated as actual structures and you must use them accordingly. The value of a function name or any other entry point is the memory address and is treated as a function pointer. If you use a symbol that does not correspond to a C++ data type (such as an unmodified module name), a syntax error occurs.
- The MASM expression evaluator treats all numbers as ULONG64 values. The C++ expression evaluator casts numbers to ULONG64 and preserves type information of all data types.
- The MASM expression evaluator lets you to use any operator together with any number. The C++ expression evaluator generates an error if you use an operator together with an incorrect data type.
- In the MASM expression evaluator, all arithmetic is performed literally. In the C++ expression evaluator, pointer arithmetic is scaled properly and is not permitted when inappropriate.
- An MASM expression can use two underscores (__) or two colons (::) to indicate members of a class. The C++ expression evaluator uses only the two-colon syntax. Debugger *output* always uses two colons.
- In an MASM expression, you should add an at sign (@) before all except the most common registers. If you omit this at sign, the register name might be interpreted as a hexadecimal number or as a symbol. In a C++ expression, this prefix is required for all registers.
- MASM expressions might contain references to source lines. These references are indicated by grave accents (`). You cannot reference source line numbers in a C++ expression.

Expression Examples

5/31/2017 • 2 min to read • [Edit Online](#)

This topics contains examples of MASM and C++ expressions that are used in various commands.

All other sections of this Help documentation use MASM expression syntax in the examples (unless otherwise noted). C++ expression syntax is very useful for manipulating structures and variables, but it does not parse the parameters of debugger commands very well.

If you are using debugger commands for general purposes or using debugger extensions, you should set MASM expression syntax as the default syntax. If you must have a specific parameter to use C++ expression syntax, use the @@() syntax.

Conditional Breakpoints

You can use comparison operators to create [conditional breakpoints](#). The following code example uses MASM expression syntax. Because the current default radix is 16, the example uses the **0n** prefix so that the number 20 is understood as a decimal number.

```
0:000> bp MyFunction+0x43 "j ( poi(MyVar)>0n20 ) ''; 'gc' "
```

In the previous example, **MyVar** is an integer in the C source. Because the MASM parser treats all symbols as addresses, the example must have the **poi** operator to dereference **MyVar**.

Conditional Expressions

The following example prints the value of **ecx** if **eax** is greater than **ebx**, 7 if **eax** is less than **ebx**, and 3 if **eax** equals **ebx**. This example uses the MASM expression evaluator, so the equal sign (=) is a comparison operator, not an assignment operator.

```
0:000> ? ecx*(eax>ebx) + 7*(eax<ebx) + 3*(eax==ebx)
```

In C++ syntax, the @ sign indicates a register, a double equal sign (==) is the comparison operator, and code must explicitly cast from **BOOL** to **int**. Therefore, in C++ syntax, the previous command becomes the following.

```
0:000> ?? @ecx*(int)(@eax>@ebx) + 7*(int)(@eax<@ebx) + 3*(int)(@eax==@ebx)
```

C++ Expression Examples

If **myInt** is a **ULONG32** value and if you are using the MASM expression evaluator, the following two examples show the value of **MyInt**.

```
0:000> ?? myInt
0:000> dd myInt L1
```

However, the following example shows the *address* of **myInt**.

```
0:000> ? myInt
```

Mixed Expression Examples

You cannot use source-line expressions in a C++ expression. The following example uses the @@() syntax to nest an MASM expression within a C++ expression. This example sets **MyPtr** equal to the address of line 43 of the Myfile.c file.

```
0:000> ?? MyPtr = @@( `myfile.c:43` )
```

The following examples set the default expression evaluator to MASM and then evaluate *Expression2* as a C++ expression, and evaluate *Expression1* and *Expression3* as MASM expressions.

```
0:000> .expr /s masm
0:000> bp Expression1 + @@( Expression2 ) + Expression3
```

If **myInt** is a ULONG64 value and if you know that this value is followed in memory by another ULONG64, you can set an access breakpoint at that location by using one of the following examples. (Note the use of pointer arithmetic.)

```
0:000> ba r8 @@( &myInt + 1 )
0:000> ba r8 myInt + 8
```

Structures

The C++ expression evaluator casts pseudo-registers to their appropriate types. For example, **\$teb** is cast as a TEB*. The following example displays the process ID.

```
kd> ?? @$teb->ClientId.UniqueProcess
```

Sign Extension

5/26/2017 • 2 min to read • [Edit Online](#)

When a 32-bit signed integer is negative, its highest bit is equal to one. When this 32-bit signed integer is cast to a 64-bit number, the high bits can be set to zero (preserving the unsigned integer and hexadecimal value of the number) or the high bits can be set to one (preserving the signed value of the number). The latter situation is called *sign extension*.

The debugger follows different rules for sign extension in MASM expressions, in C++ expressions, and when displaying numbers.

Sign Extension in MASM Expressions

Under certain conditions, numbers are automatically *sign extended* by the MASM expression evaluator. Sign extension can affect only numbers from 0x80000000 through 0xFFFFFFFF. That is, sign extension affects only numbers that can be written in 32 bits with the high bit equal to 1.

The number 0x12345678 always remains 0x00000000`12345678 when the debugger treats it as a 64-bit number. On the other hand, when 0x890ABCDE is treated as a 64-bit value, it might remain 0x00000000`890ABCDE or the MASM expression evaluator might sign extend it to 0xFFFFFFFF`890ABCDE.

A number from 0x80000000 through 0xFFFFFFFF is sign extended based on the following criteria:

- Numeric constants are never sign extended in user mode. In kernel mode, a numeric constant is sign extended unless it contains a grave accent (`) before the low bytes. For example, in kernel mode, the hexadecimal numbers **EEAA1122** and **0000000EEAA1122** are sign extended, but **0000000`EEAA1122** and **0`EEAA1122** are not.
- A 32-bit register is sign extended in both modes.
- Pseudo-registers are always stored as 64-bit values. They are not sign extended when they are evaluated. When a pseudo-register is *assigned* a value, the expression that is used is evaluated according to the standard C++ criteria.
- Individual numbers and registers in an expression can be sign extended, but no other calculations during expression evaluation are sign extended. As a result, you can mask the high bits of a number or register by using the following syntax.

```
( 0x0`FFFFFF & expression )
```

Sign Extension in C++ Expressions

When the debugger evaluates a C++ expression, the following rules apply:

- Registers and pseudo-registers are never sign extended.
- All other values are treated exactly like C++ would treat values of their type.

Displaying Sign-Extended and 64-Bit Numbers

Other than 32-bit and 16-bit registers, all numbers are stored internally within the debugger as 64-bit values. However, when a number satisfies certain criteria, the debugger displays it as a 32-bit number in command output.

The debugger uses the following criteria to determine how to display numbers:

- If the high 32 bits of a number are all zeros (that is, if the number is from 0x00000000`00000000 through 0x00000000`FFFFFF), the debugger displays the number as a 32-bit number.
- If the high 32 bits of a number are all ones and if the highest bit of the low 32 bits is also a one (that is, if the number is from 0xFFFFFFF80000000 through 0xFFFFFFF`FFFFFF), the debugger assumes the number is a sign-extended 32-bit number and displays it as a 32-bit number.
- If the previous two condition do not apply (that is, if the number is from 0x00000001`00000000 through 0xFFFFFFF`7FFFFFF) the debugger displays the number as a 64-bit number.

Because of these display rules, when a number is displayed as a 32-bit number from 0x80000000 through 0xFFFFFFF, you cannot confirm whether the high 32 bits are all ones or all zeros. To distinguish between these two cases, you must perform an additional computation on the number (such as masking one or more of the high bits and displaying the result).

[Send comments about this topic to Microsoft](#)

String Wildcard Syntax

5/31/2017 • 1 min to read • [Edit Online](#)

Some debugger commands have string parameters that accept a variety of wildcard characters. These parameters are noted on their respective reference pages.

These kinds of parameters support the following syntax features:

- An asterisk (*) represents zero or more characters.
- A question mark (?) represents any single character.
- Brackets ([]) that contain a list of characters represent any single character in the list. Exactly one character in the list is matched. Within these brackets, you can use a hyphen (-) to specify a range. For example, **Prog[er-t7]am** matches "Progeam", "Program", "Progsam", "Progtam", and "Prog7am".
- A number sign (#) represents zero or more of the preceding characters. For example, **Lo#p** matches "Lp", "Lop", "Loop", "Looop", and so on. You can also combine a number sign with brackets, so **m[ia]#n** matches "mn", "min", "man", "maan", "main", "mian", "miin", "miain", and so on.
- A plus sign (+) represents one or more of the preceding characters. For example, **Lo+p** is the same as **Lo#p**, except that **Lo+p** does not match "Lp". Similarly, **m[ia]+n** is the same as **m[ia]#n**, except that **m[ia]+n** does not match "mn". **a?+b** is also the same as **a*b**, except that **a?+b** does not match "ab".
- If you have to specify a literal number sign (#), question mark (?), opening bracket ({}), closing bracket (}), asterisk (*), or plus sign (+) character, you must add a backslash (\) in front of the character. Hyphens are always literal when you do not enclose them in brackets. But you cannot specify a literal hyphen within a bracketed list.

Parameters that specify symbols also support some additional features. In addition to the standard string wildcard characters, you can use an underscore (_) before a text expression that you use to specify a symbol. When matching this expression to a symbol, the debugger treats the underscore as any quantity of underscores, even zero. This feature applies only when you are matching symbols. It does not apply to string wildcard expressions in general. For more information about symbol syntax, see [Symbol Syntax and Symbol Matching](#).

[Send comments about this topic to Microsoft](#)

Register Syntax

5/26/2017 • 2 min to read • [Edit Online](#)

The debugger can control registers and floating-point registers.

When you use a register in an expression, you should add an at sign (@) before the register. This at sign tells the debugger that the following text is the name of a register.

If you are using MASM expression syntax, you can omit the at sign for certain very common registers. On x86-based systems, you can omit the at sign for the **eax**, **ebx**, **ecx**, **edx**, **esi**, **edi**, **ebp**, **eip**, and **efl** registers. However, if you specify a less common register without an at sign, the debugger first tries to interpret the text as a hexadecimal number. If the text contains non-hexadecimal characters, the debugger next interprets the text as a symbol. Finally, if the debugger does not find a symbol match, the debugger interprets the text as a register.

If you are using C++ expression syntax, the at sign is always required.

The **r (Registers)** command is an exception to this rule. The debugger always interprets its first argument as a register. (An at sign is not required or permitted.) If there is a second argument for the **r** command, it is interpreted according to the default expression syntax. If the default expression syntax is C++, you must use the following command to copy the **ebx** register to the **eax** register.

```
0:000> r eax = @ebx
```

For more information about the registers and instructions that are specific to each processor, see [Processor Architecture](#).

Flags on an x86-based Processor

x86-based processors also use several 1-bit registers known as *flags*. For more information about these flags and the syntax that you can use to view or change them, see [x86 Flags](#).

Registers and Threads

Each thread has its own register values. These values are stored in the CPU registers when the thread is executing and in memory when another thread is executing.

In user mode, any reference to a register is interpreted as the register that is associated with the current thread. For more information about the current thread, see [Controlling Processes and Threads](#).

In kernel mode, any reference to a register is interpreted as the register that is associated with the current register context. You can set the register context to match a specific thread, context record, or trap frame. You can display only the most important registers for the specified register context, and you cannot change their values.

[Send comments about this topic to Microsoft](#)

Pseudo-Register Syntax

5/31/2017 • 9 min to read • [Edit Online](#)

The debugger supports several pseudo-registers that hold certain values.

The debugger sets *automatic pseudo-registers* to certain useful values. *User-defined pseudo-registers* are integer variables that you can write to or read.

All pseudo-registers begin with a dollar sign (\$). If you are using MASM syntax, you can add an at sign (@) before the dollar sign. This at sign tells the debugger that the following token is a register or pseudo-register, not a symbol. If you omit the at sign, the debugger responds more slowly, because it has to search the whole symbol table.

For example, the following two commands produce the same output, but the second command is faster.

```
0:000> ? $exp
Evaluate expression: 143 = 0000008f
0:000> ? @$exp
Evaluate expression: 143 = 0000008f
```

If a symbol exists with the same name as the pseudo-register, you must add the at sign.

If you are using C++ expression syntax, the at sign (@) is always required.

The **r (Registers)** command is an exception to this rule. The debugger always interprets its first argument as a register or pseudo-register. (An at sign is not required or permitted.) If there is a second argument for the **r** command, it is interpreted according to the default expression syntax. If the default expression syntax is C++, you must use the following command to copy the **\$t2** pseudo-register to the **\$t1** pseudo-register.

```
0:000> r $t1 = @$t2
```

Automatic Pseudo-Registers

The debugger automatically sets the following pseudo-registers.

PSEUDO-REGISTER	DESCRIPTION
\$ea	The effective address of the last instruction that was executed. If this instruction does not have an effective address, the debugger displays "Bad register error". If this instruction has two effective addresses, the debugger displays the first address.
\$ea2	The second effective address of the last instruction that was executed. If this instruction does not have two effective addresses, the debugger displays "Bad register error".
\$exp	The last expression that was evaluated.

PSEUDO-REGISTER	DESCRIPTION
\$ra	<p>The return address that is currently on the stack.</p> <p>This address is especially useful in execution commands. For example, g @\$ra continues until the return address is found (although gu (Go Up) is a more precise effective way of "stepping out" of the current function).</p>
\$ip	<p>The instruction pointer register.</p> <p>x86-based processors: The same as eip. Itanium-based processors: Related to iip. (For more information, see the note following this table.) x64-based processors: The same as rip.</p>
\$eventip	<p>The instruction pointer at the time of the current event. This pointer typically matches \$ip, unless you switched threads or manually changed the value of the instruction pointer.</p>
\$previp	<p>The instruction pointer at the time of the previous event. (Breaking into the debugger counts as an event.)</p>
\$relip	<p>An instruction pointer that is related to the current event. When you are branch tracing, this pointer is the pointer to the branch source.</p>
\$scopeip	<p>The instruction pointer for the current local context (also known as the <i>scope</i>).</p>
\$exentry	<p>The address of the entry point of the first executable of the current process.</p>
\$retreg	<p>The primary return value register.</p> <p>x86-based processors: The same as eax. Itanium-based processors: The same as ret0. x64-based processors: The same as rax.</p>
\$retreg64	<p>The primary return value register, in 64-bit format.</p> <p>x86 processor: The same as the edx:eax pair.</p>
\$csp	<p>The current call stack pointer. This pointer is the register that is most representative of call stack depth.</p> <p>x86-based processors: The same as esp. Itanium-based processors: The same as bsp. x64-based processors: The same as rsp.</p>

PSEUDO-REGISTER	DESCRIPTION
\$p	The value that the last d* (Display Memory) command printed.
\$proc	The address of the current process (that is, the address of the EPROCESS block).
\$thread	The address of the current thread. In kernel-mode debugging, this address is the address of the ETHREAD block. In user-mode debugging, this address is the address of the thread environment block (TEB).
\$peb	The address of the process environment block (PEB) of the current process.
\$teb	The address of the thread environment block (TEB) of the current thread.
\$tpid	The process ID (PID) for the process that owns the current thread.
\$tid	The thread ID for the current thread.
\$dtid	
\$dpid	
\$dsid	
\$bp<i>Number</i>	The address of the corresponding breakpoint. For example, \$bp3 (or \$bp03) refers to the breakpoint whose breakpoint ID is 3. <i>Number</i> is always a decimal number. If no breakpoint has an ID of <i>Number</i> , \$bp<i>Number</i> evaluates to zero. For more information about breakpoints, see Using Breakpoints .
\$frame	The current frame index. This index is the same frame number that the .frame (Set Local Context) command uses.
\$dbgtime	The current time, according to the computer that the debugger is running on.

PSEUDO-REGISTER	DESCRIPTION
\$callret	The return value of the last function that .call (Call Function) called or that is used in an .fret/s command. The data type of \$callret is the data type of this return value.
\$extret	
\$extin	
\$clrex	
\$lastclrex	Managed debugging only: The address of the last-encountered common language runtime (CLR) exception object.
\$ptrsize	The size of a pointer. In kernel mode, this size is the pointer size on the target computer.
\$pagesize	The number of bytes in one page of memory. In kernel mode, this size is the page size on the target computer.
\$pcr	
\$pcrb	
\$argreg	
\$exr_chance	The chance of the current exception record.
\$exr_code	The exception code for the current exception record.
\$exr_numparams	The number of parameters in the current exception record.
\$exr_param0	The value of Parameter 0 in the current exception record.
\$exr_param1	The value of Parameter 1 in the current exception record.
\$exr_param2	The value of Parameter 2 in the current exception record.

PSEUDO-REGISTER	DESCRIPTION
\$exr_param3	The value of Parameter 3 in the current exception record.
\$exr_param4	The value of Parameter 4 in the current exception record.
\$exr_param5	The value of Parameter 5 in the current exception record.
\$exr_param6	The value of Parameter 6 in the current exception record.
\$exr_param7	The value of Parameter 7 in the current exception record.
\$exr_param8	The value of Parameter 8 in the current exception record.
\$exr_param9	The value of Parameter 9 in the current exception record.
\$exr_param10	The value of Parameter 10 in the current exception record.
\$exr_param11	The value of Parameter 11 in the current exception record.
\$exr_param12	The value of Parameter 12 in the current exception record.
\$exr_param13	The value of Parameter 13 in the current exception record.
\$exr_param14	The value of Parameter 14 in the current exception record.
\$bug_code	If a bug check has occurred, this is the bug code. Applies to live kernel-mode debugging and kernel crash dumps.
\$bug_param1	If a bug check has occurred, this is the value of Parameter 1. Applies to live kernel-mode debugging and kernel crash dumps.
\$bug_param2	If a bug check has occurred, this is the value of Parameter 2. Applies to live kernel-mode debugging and kernel crash dumps.

PSEUDO-REGISTER	DESCRIPTION
\$bug_param3	If a bug check has occurred, this is the value of Parameter 3. Applies to live kernel-mode debugging and kernel crash dumps.
\$bug_param4	If a bug check has occurred, this is the value of Parameter 4. Applies to live kernel-mode debugging and kernel crash dumps.

Some of these pseudo-registers might not be available in certain debugging scenarios. For example, you cannot use **\$peb**, **\$tid**, and **\$tpid** when you are debugging a user-mode minidump or certain kernel-mode dump files. There will be situations where you can learn thread information from [~ \(Thread Status\)](#) but not from **\$tid**. You cannot use the **\$previp** pseudo-register on the first debugger event. You cannot use the **\$relip** pseudo-register unless you are branch tracing. If you use an unavailable pseudo-register, a syntax error occurs.

A pseudo-register that holds the address of a structure -- such as **\$thread**, **\$proc**, **\$teb**, **\$peb**, and **\$lastclrex** -- will be evaluated according to the proper data type in the C++ expression evaluator, but not in the MASM expression evaluator. For example, the command **? \$teb** displays the address of the TEB, while the command **?? @\$teb** displays the entire TEB structure. For more information, see [Evaluating Expressions](#).

On an Itanium-based processor, the **iip** register is *bundle-aligned*, which means that it points to slot 0 in the bundle containing the current instruction, even if a different slot is being executed. So **iip** is not the full instruction pointer. The **\$ip** pseudo-register is the actual instruction pointer, including the bundle and the slot. The other pseudo-registers that hold address pointers (**\$ra**, **\$retreg**, **\$eventip**, **\$previp**, **\$relip**, and **\$exentry**) have the same structure as **\$ip** on all processors.

You can use the **r** command to change the value of **\$ip**. This change also automatically changes the corresponding register. When execution resumes, it resumes at the new instruction pointer address. This register is the only automatic pseudo-register that you can change manually.

Note In MASM syntax, you can indicate the **\$ip** pseudo-register with a period (.). You do not add an at sign (@) before this period, and do not use the period as the first parameter of the **r** command. This syntax is not permitted within a C++ expression.

Automatic pseudo-registers are similar to [automatic aliases](#). But you can use automatic aliases together with alias-related tokens (such as **\$()**), and you cannot use pseudo-registers with such tokens.

User-Defined Pseudo-Registers

There are 20 user-defined pseudo-registers (**\$t0**, **\$t1**, ..., **\$t19**). These pseudo-registers are variables that you can read and write through the debugger. You can store any integer value in these pseudo-registers. They can be especially useful as loop variables.

To write to one of these pseudo-registers, use the [r \(Registers\)](#) command, as the following example shows.

```
0:000> r $t0 = 7
0:000> r $t1 = 128*poi(MyVar)
```

Like all pseudo-registers, you can use the user-defined pseudo-register in any expression, as the following example shows.

```
0:000> bp $t3
0:000> bp @$t4
0:000> ?? @$t1 + 4*@$t2
```

A pseudo-register is always typed as an integer, unless you use the **?** switch together with the **r** command. If you use this switch, the pseudo-register acquires the type of whatever is assigned to it. For example, the following command assigns the **UNICODE_STRING**** type and the **0x0012FFBC** value to **\$t15**.

```
0:000> r? $t15 = * (UNICODE_STRING*) 0x12ffbc
```

User-defined pseudo-registers use zero as the default value when the debugger is started.

Note The aliases **\$u0**, **\$u1**, ..., **\$u9** are not pseudo-registers, despite their similar appearance. For more information about these aliases, see [Using Aliases](#).

Example

The following example sets a breakpoint that is hit every time that the current thread calls **NtOpenFile**. But this breakpoint is not hit when other threads call **NtOpenFile**.

```
kd> bp /t @$thread nt!ntopenfile
```

Example

The following example executes a command until the register holds a specified value. First, put the following code for conditional stepping in a script file named "eaxstep".

```
.if (@eax == 1234) { .echo 1234 } .else { t "$<eaxstep" }
```

Next, issue the following command.

```
t "$<eaxstep"
```

The debugger performs a step and then runs your command. In this case, the debugger runs the script, which either displays **1234** or repeats the process.

[Send comments about this topic to Microsoft](#)

Source Line Syntax

5/31/2017 • 1 min to read • [Edit Online](#)

You can specify source file line numbers as all or part of an MASM expression. These numbers evaluate to the offset of the executable code that corresponds to this source line.

Note You cannot use source line numbers as part of a C++ expression. For more information about when MASM and C++ expression syntax is used, see [Evaluating Expressions](#).

You must enclose source file and line number expressions by grave accents (`). The following example shows the full format for source file line numbers.

```
`[[Module!]Filename][:LineNumber]`
```

If you have multiple files that have identical file names, *Filename* should include the whole directory path and file name. This directory path should be the one that is used at compilation time. If you supply only the file name or only part of the path and if there are multiple matches, the debugger uses the first match that it finds.

If you omit *Filename*, the debugger uses the source file that corresponds to the current program counter.

LineNumber is read as a decimal number unless you precede it with **0x**, regardless of the current default radix. If you omit *LineNumber*, the expression evaluates to the initial address of the executable that corresponds to the source file.

Source line expressions are not evaluated in CDB unless you issue a [.lines \(Toggle Source Line Support\)](#) command or you include the [-lines command-line option](#) when you start WinDbg..

For more information about source debugging, see [Debugging in Source Mode](#).

[Send comments about this topic to Microsoft](#)

Address and Address Range Syntax

5/31/2017 • 4 min to read • [Edit Online](#)

There are several ways to specify addresses in the debugger.

Addresses are always *virtual addresses*, except when the documentation specifically indicates another kind of address. In user mode, the debugger interprets virtual addresses according to the page directory of the [current process](#). In kernel mode, the debugger interprets virtual addresses according to the page directory of the process that the [process context](#) specifies. You can also directly set the *user-mode address context*. For more information about the user-mode address context, see [.context \(Set User-Mode Address Context\)](#).

Address Modes and Segment Support

On x86-based platforms, CDB and KD support the following addressing modes. These modes are distinguished by their prefixes.

PREFIX	NAME	ADDRESS TYPES
%	flat	32-bit addresses (also 16-bit selectors that point to 32-bit segments) and 64-bit addresses on 64-bit systems.
&	virtual 86	Real-mode addresses. x86-based only.
#	plain	Real-mode addresses. x86-based only.

The difference between the plain and virtual 86 modes is that a plain 16-bit address uses the segment value as a selector and looks up the segment descriptor. But a virtual 86 address does not use selectors and instead maps directly into the lower 1 MB.

If you access memory through an addressing mode that is not the current default mode, you can use the address mode prefixes to override the current address mode.

Address Arguments

Address arguments specify the location of variables and functions. The following table explains the syntax and meaning of the various addresses that you can use in CDB and KD.

SYNTAX	MEANING
offset	The absolute address in virtual memory space, with a type that corresponds to the current execution mode. For example, if the current execution mode is 16 bit, the offset is 16 bit. If the execution mode is 32-bit segmented, the offset is 32-bit segmented.
&[[segment:]] offset	The real address. x86-based and x64-based.

SYNTAX	MEANING
<code>%segment:[[offset]]</code>	A segmented 32-bit or 64-bit address. x86-based and x64-based.
<code>%[[offset]]</code>	An absolute address (32-bit or 64-bit) in virtual memory space. x86-based and x64-based.
<code>name[[+ -]] offset</code>	A flat 32-bit or 64-bit address. <i>name</i> can be any symbol. <i>offset</i> specifies the offset. This offset can be whatever address mode its prefix indicates. No prefix specifies a default mode address. You can specify the offset as a positive (+) or negative (-) value.

Use the **dg (Display Selector)** command to view segment descriptor information.

In MASM expressions, you can also use the **poi** operator to dereference any pointer. For example, if the pointer at address 0x00123456 points to address location 0x00420000, the following two commands are equivalent.

```
0:000> dd 420000
0:000> dd poi(123456)
```

In C++ expressions, pointers behave like pointers in C++. However, numbers are interpreted as integers. If you have to deference an actual number, you must cast it first, as the following example shows.

```
0:000> dd *( (long*) 0x123456 )
```

Some **pseudo-registers** also hold common addresses, such as the current program counter location.

You can also indicate an address in an application by specifying the original source file name and line number. For more information about how to specify this information, see [Source Line Syntax](#).

Address Ranges

You can specify an address range by a pair of addresses or by an address and object count.

To specify a range by a pair of addresses, specify the starting address and the ending address. For example, the following example is a range of 8 bytes, beginning at the address 0x00001000.

```
0x00001000  0x00001007
```

To specify an address range by an address and object count, specify an address argument, the letter L (uppercase or lowercase), and a value argument. The address specifies the starting address. The value specifies the number of objects to be examined or displayed. The size of the object depends on the command. For example, if the object size is 1 byte, the following example is a range of 8 bytes, beginning at the address 0x00001000.

```
0x00001000  L8
```

However, if the object size is a double word (32 bits or 4 bytes), the following two ranges each give an 8-byte range.

```
0x00001000 0x00001007  
0x00001000 L2
```

There are two other ways to specify the value (the **LSize** range specifier):

- **L? Size** (with a question mark) means the same as **LSize**, except that **L? Size** removes the debugger's automatic range limit. Typically, there is a range limit of 256 MB, because larger ranges are typographic errors. If you want to specify a range that is larger than 256 MB, you must use the **L? Size** syntax.
- **L- Size** (with a hyphen) specifies a range of length *Size* that ends at the given address. For example, **80000000 L20** specifies the range from 0x80000000 through 0x8000001F, and **80000000 L-20** specifies the range from 0x7FFFFFFE0 through 0x7FFFFFFF.

Some commands that ask for address ranges accept a single address as the argument. In this situation, the command uses some default object count to compute the size of the range. Typically, commands for which the address range is the final parameter permit this syntax. For the exact syntax and the default range size for each command, see the reference topics for each command.

[Send comments about this topic to Microsoft](#)

Thread Syntax

5/26/2017 • 1 min to read • [Edit Online](#)

Many debugger commands have thread identifiers as their parameters. A tilde (~) appears before the thread identifier.

The thread identifier can be one of the following values.

THREAD IDENTIFIER	DESCRIPTION
~.	The current thread.
~#	The thread that caused the current exception or debug event.
~*	All threads in the process.
~ <i>Number</i>	The thread whose index is <i>Number</i> .
~~[<i>TID</i>]	The thread whose thread ID is <i>TID</i> . (The brackets are required And you cannot add a space between the second tilde and the opening bracket.)
~[<i>Expression</i>]	The thread whose thread ID is the integer to which the numerical <i>Expression</i> resolves.

Threads are assigned indexes as they are created. Note that this number differs from the thread ID that the Microsoft Windows operating system uses.

When debugging begins, the current thread is the one that caused the present exception or debug event (or the active thread when the debugger attached to the process). That thread remains the current thread until you specify a new one by using a [~s \(Set Current Thread\)](#) command or by using the [Processes and Threads window](#) in WinDbg.

Thread identifiers typically appear as command prefixes. Note that not all wildcard characters are available in all commands that use thread identifiers.

An example of the ~[*Expression*] syntax would be `~[@$t0]`. In this example, the thread changes depending on the value of a user-defined pseudo-register. This syntax allows debugger scripts to programmatically select a thread.

Controlling Threads in Kernel Mode

In kernel mode, you cannot control threads by using thread identifiers. For more information about how to access thread-specific information in kernel mode, see [Changing Contexts](#).

Note You can use the tilde character (~) to specify threads during user-mode debugging. In kernel-mode debugging, you can use the tilde to specify processors. For more information about how to specify processors, see [Multiprocessor Syntax](#).

[Send comments about this topic to Microsoft](#)

Process Syntax

5/26/2017 • 1 min to read • [Edit Online](#)

Many debugger commands have process identifiers as their parameters. A vertical bar (|) appears before the process identifier.

The process identifier can be one of the following values.

PROCESS IDENTIFIER	DESCRIPTION
.	The current process.
#	The process that caused the current exception or debug event.
*	All processes.
Number	The process whose ordinal is <i>Number</i> .
~[PID]	The process whose process ID is <i>PID</i> . (The brackets are required and you cannot add a space between the tilde (~) and the opening bracket.)
[Expression]	The process whose process ID is the integer to which the numerical <i>Expression</i> resolves.

Processes are assigned ordinals as they are created. Note that this number differs from the process ID (PID) that the Microsoft Windows operating system uses.

The current process defines the memory space and the set of threads that are used. When debugging begins, the current process is the one that caused the present exception or debug event (or the process that the debugger attached to). That process remains the current process until you specify a new one by using a [|s \(Set Current Process\)](#) command or by using the [Processes and Threads window](#) in WinDbg.

Process identifiers are used as parameters in several commands, frequently as the command prefix. Note that WinDbg and CDB can debug child processes that the original process created. WinDbg and CDB can also attach to multiple unrelated processes.

An example of the |[Expression] syntax would be |[@\$t0]. In this example, the process changes depending on the value of a user-defined pseudo-register. This syntax allows debugger scripts to programmatically select a process.

Controlling Processes in Kernel Mode

In kernel mode, you cannot control processes by using process identifiers. For more information about how to access process-specific information in kernel mode, see [Changing Contexts](#).

[Send comments about this topic to Microsoft](#)

System Syntax

5/26/2017 • 1 min to read • [Edit Online](#)

Many debugger commands have process identifiers as their parameters.

Two vertical bars (||) appear before the system identifier. The system identifier can be one of the following values.

SYSTEM IDENTIFIER	DESCRIPTION
.	The current system
#	The system that caused the current exception or debug event.
*	All systems.
<i>ddd</i>	The system whose ordinal is <i>ddd</i> .

Systems are assigned ordinals in the order that the debugger attaches to them.

When debugging begins, the current system is the one that caused the present exception or debug event (or the one that the debugger most recently attached to). That system remains the current system until you specify a new one by using a [||s \(Set Current System\)](#) command or by using the [Processes and Threads window](#) in WinDbg.

[Send comments about this topic to Microsoft](#)

Multiprocessor Syntax

5/31/2017 • 2 min to read • [Edit Online](#)

KD and kernel-mode WinDbg support multiple processor debugging. You can perform this kind of debugging on any multiprocessor platform.

Processors are numbered zero through *n*.

If the current processor is processor 0 (that is, if it is the processor that currently caused the debugger to be active), you can examine the other non-current processors (processors one through *n*). However, you cannot change anything in the non-current processors. You can only view their state.

Selecting a Processor

You can use the [.echocpnum \(Show CPU Number\)](#) command to display the processor numbers of the current processor. The output from this command enables you to immediately tell when you are working on a multiple processor system by the text in the kernel debugging prompt.

In the following example, **0:** in front of the **kd>** prompt indicates that you are debugging the first processor in the computer.

```
0: kd>
```

Use the [~s \(Change Current Processor\)](#) command to switch between processors, as the following example shows.

```
0: kd> ~1s
1: kd>
```

Now you are debugging the second processor in the computer.

You might have to change processors on a multiprocessor system if you encounter a break and you cannot understand the stack trace. The break might have occurred on a different processor.

Specifying Processors in Other Commands

You can add a processor number before several commands. This number is not preceded by a tilde (~), except in the [~\\$](#) command.

Note In user-mode debugging, the tilde is used to specify threads. For more information about this syntax, see [Thread Syntax](#).

Processor IDs do not have to be referred to explicitly. Instead, you can use a numerical expression that resolves to an integer that corresponds to a processor ID. To indicate that the expression should be interpreted as a processor, use the following syntax.

```
||[Expression]
```

In this syntax, the square brackets are required, and *Expression* stands for any numerical expression that resolves to an integer that corresponds to a processor ID.

In the following example, the processor changes depending on the value of a user-defined pseudo-register.

```
||[$t0]
```

Examples

The following example uses the **k (Display Stack Backtrace)** command to display a stack trace from processor two.

```
1: kd> 2k
```

The following example uses the **r (Registers)** command to display the **eax** register of processor three.

```
1: kd> 3r eax
```

However, the following command gives a syntax error, because you cannot change the state of a processor other than the current processor.

```
1: kd> 3r eax=808080
```

Breakpoints

During kernel debugging, the **bp, bu, bm (Set Breakpoint)** and **ba (Break on Access)** commands apply to all processors of a multiple processor computer.

For example, if the current processor is three, you can enter the following command to put a breakpoint at **SomeAddress**.

```
1: kd> bp SomeAddress
```

Then, any processor (not only processor one) that executes at that address causes a breakpoint trap.

Displaying Processor Information

You can use the **!running** extension to display the status of each processor on the target computer. For each processor, **!running** can also display the current and next thread fields from the process control block (PRCB), the state of the 16 built-in queued spinlocks, and a stack trace.

You can use the **!cpuinfo** and **!cpuid** extensions to display information about the processors themselves.

[Send comments about this topic to Microsoft](#)

Command Tokens

5/26/2017 • 1 min to read • [Edit Online](#)

This section of the reference discusses the various tokens used within debugger commands and meta-commands.

These tokens include:

`;` (Command Separator)

`{ }` (Block Delimiter)

`{} (Alias Interpreter)`

`## (Comment Specifier)`

`* (Comment Line Specifier)`

`.block`

`.break`

`.catch`

`.continue`

`.do`

`.else`

`.elsif`

`.for`

`.foreach`

`.if`

`.leave`

`.printf`

`.while`

[Send comments about this topic to Microsoft](#)

;(Command Separator)

5/31/2017 • 1 min to read • [Edit Online](#)

The semicolon (;) character is used to separate multiple commands on a single line.

```
Command1 ; Command2 [; Command3 ...]
```

Parameters

Command1, Command2, ...

The commands to be executed.

Remarks

Commands are executed sequentially from left to right. All commands on a single line refer to the current thread, unless otherwise specified. If a command causes the thread to execute, the remaining commands on the line will be deferred until that thread stops on a debug event.

A small number of commands cannot be followed by a semicolon, because they automatically take the entire remainder of the line as their argument. These include **as (Set Alias)**, **\$< (Run Script File)**, **\$>< (Run Script File)**, and any command beginning with the *** (Comment Line Specifier)** token.

Here is an example. This executes the current program to source line 123, prints the value of **counter**, then resumes execution:

```
0:000> g `:123`; ? poi(counter); g
```

[Send comments about this topic to Microsoft](#)

{ } (Block Delimiter)

5/31/2017 • 1 min to read • [Edit Online](#)

A pair of braces ({ }) is used to surround a block of statements within a debugger command program.

```
Statements { Statements } Statements
```

Additional Information

For information about debugger command programs and control flow tokens, see [Using Debugger Command Programs](#).

Remarks

When each block is entered, all aliases within the block are evaluated. If you alter the value of an alias at some point within a command block, commands subsequent to that point will not use the new alias value unless they are within a subordinate block.

Each block must begin with a control flow token. If you wish to create a block for the sole purpose of evaluating aliases, you should prefix it with the **.block** token.

[Send comments about this topic to Microsoft](#)

`{} (Alias Interpreter)`

5/31/2017 • 2 min to read • [Edit Online](#)

A dollar sign followed by a pair of braces (`{}`) evaluates to a variety of values related to the specified user-named alias.

```
Text ${Alias} Text
Text ${/d:Alias} Text
Text ${/f:Alias} Text
Text ${/n:Alias} Text
Text ${/v:Alias} Text
```

Parameters

Alias

Specifies the name of the alias to be expanded or evaluated. *Alias* must be a user-named alias or the *Variable* value used by the **.foreach** token.

/d

Evaluates to one or zero depending on whether the alias is currently defined. If the alias is defined, `{}{/v:Alias}` is replaced by 1; if the alias is not defined, `{}{/v:Alias}` is replaced by 0.

/f

Evaluates to the alias equivalent if the alias is currently defined. If the alias is defined, `{}{/f:Alias}` is replaced by the alias equivalent; if the alias is not defined, `{}{/f:Alias}` is replaced by an empty string.

/n

Evaluates to the alias name if the alias is currently defined. If the alias is defined, `{}{/n:Alias}` is replaced by the alias name; if the alias is not defined, `{}{/n:Alias}` is not replaced but retains its literal value of `{}{/n:Alias}`.

/v

Prevents any alias evaluation. Regardless of whether *Alias* is defined, `{}{/v:Alias}` always retains its literal value of `{}{/v:Alias}`.

Additional Information

For an explanation of how to use aliases, see [Using Aliases](#).

Remarks

If no switches are used and the alias is currently defined, `{}{Alias}` is replaced by the alias equivalent. If no switches are used and the alias is not defined, `{}{Alias}` always retains its literal value of `{}{Alias}`.

One advantage of using the `{}` token is that the alias will be evaluated even if it is adjacent to other characters. Without this token, the debugger only replaces aliases that are separated from other tokens by a space.

As indicated, there are circumstances where the `{}` token is not replaced by anything but retains its literal value. This occurs when no switch is used and *Alias* is undefined, when the **/n** switch is used and *Alias* is undefined, and always when the **/v** switch is used. In these circumstances, the token retains its literal value, including the dollar sign and the braces. Therefore, if this is used as the parameter of a command, a syntax error will result, unless that parameter accepts arbitrary text strings.

There is, however, one exception to this. If you use `{}{/v:Alias}` as the first parameter to the [as \(Set Alias\)](#) or [aS](#)

(Set Alias) command, this token will be treated as the string *Alias* alone, not as the string `$/v:Alias`. This only works with the **as**, **aS**, and **ad** commands, and it only works when the **/v** switch is used—it will not work with `$/n:Alias` or `/${Alias}` when they retain their literal values.

Alias must be a user-named alias or the *Variable* value used by the **.foreach** token—not a fixed-name alias. If there is a fixed-name alias within the string *Alias*, it will be replaced before the `/${ }` token is evaluated.

[Send comments about this topic to Microsoft](#)

\$\$ (Comment Specifier)

5/31/2017 • 1 min to read • [Edit Online](#)

If two dollar signs (**\$\$**) appear at the start of a command, then the rest of the line is treated as a comment, unless the comment is terminated by a semicolon.

```
$$ [any text]
```

Remarks

The **\$\$** token is parsed like any other debugger command. Therefore, if you want to create a comment after another command, you must precede the **\$\$** token with a semicolon.

The **\$\$** token will cause the text after it to be ignored until the end of the line or until a semicolon is encountered. A semicolon terminates the comment; text after the semicolon is parsed as a standard command. This differs from *** (Comment Line Specifier)**, which makes the remainder of the line a comment even if a semicolon is present.

For example, the following command will display **eax** and **ebx**, but not **ecx**:

```
0:000> r eax; $$ some text; r ebx; * more text; r ecx
```

Text prefixed by the ***** or **\$\$** tokens is not processed in any way. If you are performing remote debugging, a comment entered in the debugging server will not be visible in the debugging client, nor vice-versa. If you wish to make comment text appear in the Debugger Command window in a way visible to all parties, you should use **.echo (Echo Comment)**.

[Send comments about this topic to Microsoft](#)

* (Comment Line Specifier)

5/31/2017 • 1 min to read • [Edit Online](#)

If the asterisk (`*`) character is at the start of a command, then the rest of the line is treated as a comment, even if a semicolon appears after it.

```
* [any text]
```

Remarks

The `*` token is parsed like any other debugger command. Therefore, if you want to create a comment after another command, you must precede the `*` token with a semicolon.

The `*` token will cause the remainder of the line to be ignored, even if a semicolon appears after it. This differs from [\\$\\$ \(Comment Specifier\)](#), which creates a comment that can be terminated by a semicolon.

For example, the following command will display `eax` and `ebx`, but not `ecx`:

```
0:000> r eax; $$ some text; r ebx; * more text; r ecx
```

Text prefixed by the `*` or `$$` tokens is not processed in any way. If you are performing remote debugging, a comment entered in the debugging server will not be visible in the debugging client, nor vice-versa. If you wish to make comment text appear in the Debugger Command window in a way visible to all parties, you should use [.echo \(Echo Comment\)](#).

[Send comments about this topic to Microsoft](#)

.block

5/31/2017 • 1 min to read • [Edit Online](#)

The **.block** token performs no action; it is used solely to introduce a block of statements.

```
Commands ; .block { Commands } ; Commands
```

Additional Information

For information about using a new block to evaluate an alias, see [Using Aliases](#) and [as, aS \(Set Alias\)](#).

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

Blocks of commands are surrounded by braces. When each block is entered, all aliases within the block are evaluated. If you alter the value of an alias at some point within a command block, commands subsequent to that point will not use the new alias value unless they are within a subordinate block.

Each block must begin with a control flow token. If you wish to create a block for the sole purpose of evaluating aliases, you should prefix it with the **.block** token, since this token has no effect other than to allow a block to be introduced.

[Send comments about this topic to Microsoft](#)

.break

5/31/2017 • 1 min to read • [Edit Online](#)

The **.break** token behaves like the **break** keyword in C.

```
.for (...) { ... ; .if (Condition) .break ; ...}  
.while (...) { ... ; .if (Condition) .break ; ...}  
.do { ... ; .if (Condition) .break ; ...} (...)
```

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

The **.break** token can be used within any **.for**, **.while**, or **.do** loop.

Since there is no control flow token equivalent to the C **goto** statement, you will usually use the **.break** token within an **.if** conditional, as shown in the syntax examples above. However, this is not actually required.

[Send comments about this topic to Microsoft](#)

.catch

5/31/2017 • 1 min to read • [Edit Online](#)

The **.catch** token is used to prevent a program from terminating if an error occurs.

It does not behave like the **catch** keyword in C++.

```
Commands ; .catch { Commands } ; Commands
```

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

The **.catch** token is followed by braces enclosing one or more commands.

If a command within a **.catch** block generates an error, the error message is displayed, all remaining commands within the braces are ignored, and execution resumes with the first command after the closing brace.

If **.catch** is not used, an error will terminate the entire debugger command program.

You can use [.leave](#) to exit from a **.catch** block.

[Send comments about this topic to Microsoft](#)

.continue

5/31/2017 • 1 min to read • [Edit Online](#)

The **.continue** token behaves like the **continue** keyword in C.

```
.for (...) { ... ; .if (Condition) .continue ; ... }

.while (...) { ... ; .if (Condition) .continue ; ... }

.do { ... ; .if (Condition) .continue ; ... } (...)
```

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

The **.continue** token can be used within any **.for**, **.while**, or **.do** loop.

Since there is no control flow token equivalent to the C `goto` statement, you will usually use the **.continue** token within an **.if** conditional, as shown in the syntax examples above. However, this is not actually required.

[Send comments about this topic to Microsoft](#)

.do

5/31/2017 • 1 min to read • [Edit Online](#)

The **.do** token behaves like the **do** keyword in C, except that the word "while" is not used before the condition.

```
.do { Commands } (Condition)
```

Syntax Elements

Commands

Specifies one or more commands that will be executed repeatedly as long as the condition is true -- but will always be executed at least once. This block of commands needs to be enclosed in braces, even if it consists of a single command. Multiple commands should be separated by semicolons, but the final command before the closing brace does not need to be followed by a semicolon.

Condition

Specifies a condition. If this evaluates to zero, it is treated as false; otherwise it is true. Enclosing *Condition* in parentheses is optional. *Condition* must be an expression, not a debugger command. It will be evaluated by the default expression evaluator (MASM or C++). For details, see [Numerical Expression Syntax](#).

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

The **.break** and **.continue** tokens can be used to exit or restart the *Commands* block.

[Send comments about this topic to Microsoft](#)

.else

5/31/2017 • 1 min to read • [Edit Online](#)

The **.else** token behaves like the **else** keyword in C.

```
.if (Condition) { Commands } .else { Commands }

.if (Condition) { Commands } .elseif (Condition) { Commands } .else { Commands }
```

Syntax Elements

Commands

Specifies one or more commands that will be executed conditionally. This block of commands needs to be enclosed in braces, even if it consists of a single command. Multiple commands should be separated by semicolons, but the final command before the closing brace does not need to be followed by a semicolon.

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

[Send comments about this topic to Microsoft](#)

.elseif

5/31/2017 • 1 min to read • [Edit Online](#)

The **.elseif** token behaves like the **else if** keyword combination in C.

```
.if (Condition) { Commands } .elseif (Condition) { Commands }  
.if (Condition) { Commands } .elseif (Condition) { Commands } .else { Commands }
```

Syntax Elements

Condition

Specifies a condition. If this evaluates to zero, it is treated as false; otherwise it is true. Enclosing *Condition* in parentheses is optional. *Condition* must be an expression, not a debugger command. It will be evaluated by the default expression evaluator (MASM or C++). For details, see [Numerical Expression Syntax](#).

Commands

Specifies one or more commands that will be executed conditionally. This block of commands needs to be enclosed in braces, even if it consists of a single command. Multiple commands should be separated by semicolons, but the final command before the closing brace does not need to be followed by a semicolon.

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

[Send comments about this topic to Microsoft](#)

.for

5/31/2017 • 1 min to read • [Edit Online](#)

The **.for** token behaves like the **for** keyword in C, except that multiple increment commands must be separated by semicolons, not by commas.

```
.for (InitialCommand ; Condition ; IncrementCommands) { Commands }
```

Syntax Elements

InitialCommand

Specifies a command that will be executed before the loop begins. Only a single initial command is permitted.

Condition

Specifies a condition. If this evaluates to zero, it is treated as false; otherwise it is true. Enclosing *Condition* in parentheses is optional. *Condition* must be an expression, not a debugger command. It will be evaluated by the default expression evaluator (MASM or C++). For details, see [Numerical Expression Syntax](#).

IncrementCommands

Specifies one or more commands that will be executed at the conclusion of each loop. If you wish to use multiple increment commands, separate them by semicolons but do not enclose them in braces.

Commands

Specifies one or more commands that will be executed repeatedly as long as the condition is true. This block of commands needs to be enclosed in braces, even if it consists of a single command. Multiple commands should be separated by semicolons, but the final command before the closing brace does not need to be followed by a semicolon.

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

If all the work is being done by the increment commands, you can omit *Condition* entirely and simply use an empty pair of braces.

Here is an example of a **.for** statement with multiple increment commands:

```
0:000> .for (r eax=0; @eax < 7; r eax=@eax+1; r ebx=@ebx+1) { .... }
```

The **.break** and **.continue** tokens can be used to exit or restart the *Commands* block.

[Send comments about this topic to Microsoft](#)

.foreach

5/31/2017 • 2 min to read • [Edit Online](#)

The **.foreach** token parses the output of one or more debugger commands and uses each value in this output as the input to one or more additional commands.

```
.foreach [Options] ( Variable { InCommands } ) { OutCommands }

.foreach [Options] /s ( Variable "InString" ) { OutCommands }

.foreach [Options] /f ( Variable "InFile" ) { OutCommands }
```

Syntax Elements

Options

Can be any combination of the following options:

/pS InitialSkipNumber

Causes some initial tokens to be skipped. *InitialSkipNumber* specifies the number of output tokens that will not be passed to the specified *OutCommands*.

/ps SkipNumber

Causes tokens to be skipped repeatedly each time a command is processed. After each time a token is passed to the specified *OutCommands*, a number of tokens equal to the value of *SkipNumber* will be ignored.

Variable

Specifies a variable name. This variable will be used to hold the output from each command in the *InCommands* string; you can reference *Variable* by name in the parameters passed to the *OutCommands*. Any alphanumeric string can be used, although using a string that can also pass for a valid hexadecimal number or debugger command is not recommended. If the name used for *Variable* happens to match an existing global variable, local variable, or alias, their values will not be affected by the **.foreach** command.

InCommands

Specifies one or more commands whose output will be parsed; the resulting tokens will be passed to *OutCommands*. The output from *InCommands* is not displayed.

InString

Used with **/s**. Specifies a string that will be parsed; the resulting tokens will be passed to *OutCommands*.

InFile

Used with **/f**. Specifies a text file that will be parsed; the resulting tokens will be passed to *OutCommands*. The file name *InFile* must be enclosed in quotation marks.

OutCommands

Specifies one or more commands which will be executed for each token. Whenever the *Variable* string occurs it will be replaced by the current token.

Note When the string *Variable* appears within *OutCommands*, it must be surrounded by spaces. If it is adjacent to any other text -- even a parenthesis -- it will not be replaced by the current token value, unless you use the **\$()** (**Alias Interpreter**) token.

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

When the output from *InCommands*, the *InString* string, or the *InFile* file is parsed, any number of spaces, tabs, or carriage returns is treated as a single delimiter. Each of the resulting pieces of text is used to replace *Variable* when it appears within *OutCommands*.

Here is an example of a **.foreach** statement that uses the **dds** command on each token found in the file *myfile.txt*:

```
0:000> .foreach /f ( place "g:\myfile.txt") { dds place }
```

The **/pS** and **/ps** flags can be used to pass only certain tokens to the specified *OutCommands*. For example, the following statement will skip the first two tokens in the *myfile.txt* file and then pass the third to **dds**. After each token that is passed, it will skip four tokens. The result is that **dds** will be used with the 3rd, 8th, 13th, 18th, and 23rd tokens, and so on:

```
0:000> .foreach /pS 2 /ps 4 /f ( place "g:\myfile.txt") { dds place }
```

For more examples that use the **.foreach** token, see [Debugger Command Program Examples](#).

[Send comments about this topic to Microsoft](#)

.if

5/31/2017 • 1 min to read • [Edit Online](#)

The **.if** token behaves like the **if** keyword in C.

```
.if (Condition) { Commands }

.if (Condition) { Commands } .else { Commands }

.if (Condition) { Commands } .elseif (Condition) { Commands }

.if (Condition) { Commands } .elseif (Condition) { Commands } .else { Commands }
```

Syntax Elements

Condition

Specifies a condition. If this evaluates to zero, it is treated as false; otherwise it is true. Enclosing *Condition* in parentheses is optional. *Condition* must be an expression, not a debugger command. It will be evaluated by the default expression evaluator (MASM or C++). For details, see [Numerical Expression Syntax](#).

Commands

Specifies one or more commands that will be executed conditionally. This block of commands needs to be enclosed in braces, even if it consists of a single command. Multiple commands should be separated by semicolons, but the final command before the closing brace does not need to be followed by a semicolon.

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

[Send comments about this topic to Microsoft](#)

.leave

5/31/2017 • 1 min to read • [Edit Online](#)

The **.leave** token is used to exit from a **.catch** block.

```
.catch { ... ; .if (Condition) .leave ; ... }
```

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

When a **.leave** token is encountered within a **.catch** block, the program exits from the block, and execution resumes with the first command after the closing brace.

Since there is no control flow token equivalent to the C **goto** statement, you will usually use the **.leave** token within an **.if** conditional, as shown in the syntax examples above. However, this is not actually required.

[Send comments about this topic to Microsoft](#)

.printf

5/31/2017 • 3 min to read • [Edit Online](#)

The **.printf** token behaves like the **printf** statement in C.

```
.printf [/D] [Option] "FormatString" [, Argument , ...]
```

Syntax Elements

/D

Specifies that the format string contains [Debugger Markup Language](#) (DML).

Option

(WinDbg only) Specifies the type of text message that WinDbg should interpret the FormatString as. WinDbg assigns each type of Debugger Command window message a background and text color; choosing one of these options causes the message to be displayed in the appropriate colors. The default is to display the text as a normal-level message. For more information on message colors and how to set them, see [View | Options](#).

The following options are available.

OPTION	TYPE OF MESSAGE	TITLE OF COLORS IN OPTIONS DIALOG BOX
/od	debuggee	Debuggee level command window
/oD	debuggee prompt	Debuggee prompt level command window
/oe	error	Error level command window
/on	normal	Normal level command window
/op	prompt	Prompt level command window
/oP	prompt registers	Prompt registers level command window
/os	symbols	Symbol message level command window
/ov	verbose	Verbose level command window
/ow	warning	Warning level command window

FormatString

Specifies the format string, as in **printf**. In general, conversion characters work exactly as in C. For the floating-point conversion characters, the 64-bit argument is interpreted as a 32-bit floating-point number unless the **I** modifier is used.

The **%p** conversion character is supported, but it represents a pointer in the target's virtual address space. It must not have any modifiers and it uses the debugger's internal address formatting. The following additional conversion characters are supported.

CHARACTER	ARGUMENT TYPE	ARGUMENT	TEXT PRINTED
%p	ULONG64	A pointer in the target's virtual address space.	The value of the pointer.
%N	DWORD_PTR (32 or 64 bits, depending on the host's architecture)	A pointer in the host's virtual address space.	The value of the pointer. (This is equivalent to the standard C %p character.)
%l	ULONG64	Any 64-bit value.	The specified value. If this is greater than 0xFFFFFFFF, it is printed as a 64-bit address; otherwise it is printed as a 32-bit address.
%ma	ULONG64	The address of a NULL-terminated ASCII string in the target's virtual address space.	The specified string.
%mu	ULONG64	The address of a NULL-terminated Unicode string in the target's virtual address space.	The specified string.
%msa	ULONG64	The address of an ANSI_STRING structure in the target's virtual address space.	The specified string.
%msu	ULONG64	The address of a UNICODE_STRING structure in the target's virtual address space.	The specified string.
%y	ULONG64	The address of a debugger symbol in the target's virtual address space.	A string containing the name of the specified symbol (and displacement, if any).

CHARACTER	ARGUMENT TYPE	ARGUMENT	TEXT PRINTED
%ly	ULONG64	The address of a debugger symbol in the target's virtual address space.	A string containing the name of the specified symbol (and displacement, if any), as well as any available source line information.

Arguments

Specifies arguments for the format string, as in **printf**. The number of arguments that are specified should match the number of conversion characters in *FormatString*. Each argument is an expression that will be evaluated by the default expression evaluator (MASM or C++). For details, see [Numerical Expression Syntax](#).

Additional Information

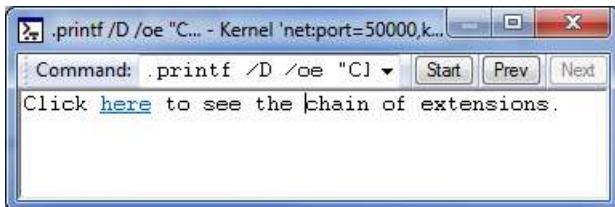

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

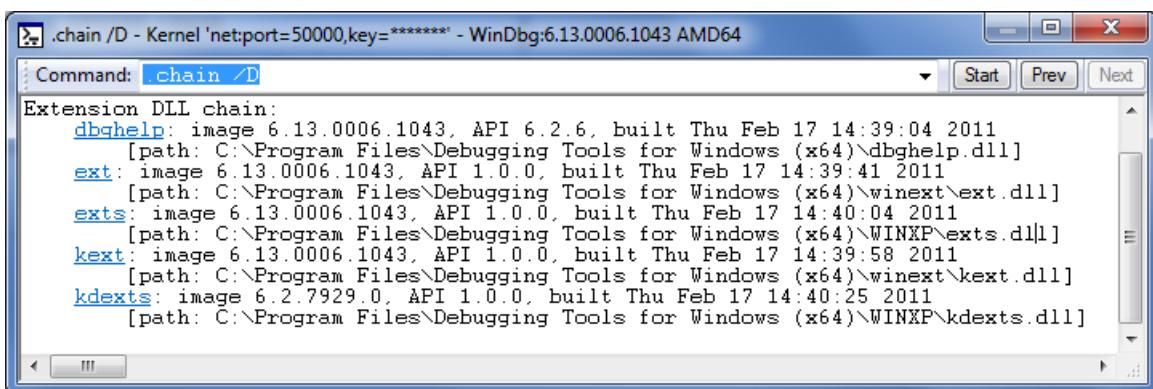

The color settings that you can choose by using the *Options* parameter are by default all set to black text on a white background. To make best use of these options, you must first use [View | Options](#) to open the Options dialog box and change the color settings for Debugger Command window messages.

The following example shows how to include a DML tag in the format string.

```
.printf /D "Click <link cmd=\".chain /D\">here</link> to see extensions DLLs."
```

The output shown in the preceding image has a link that you can click to execute the command specified in the `<link>` tag. The following image shows the result of clicking the link.

For information about DML tags, see `dml.doc` in the installation folder for Debugging Tools for Windows.

[Send comments about this topic to Microsoft](#)

.while

5/31/2017 • 1 min to read • [Edit Online](#)

The **.while** token behaves like the **while** keyword in C.

```
.while (Condition) { Commands }
```

Syntax Elements

Condition

Specifies a condition. If this evaluates to zero, it is treated as false; otherwise it is true. Enclosing *Condition* in parentheses is optional. *Condition* must be an expression, not a debugger command. It will be evaluated by the default expression evaluator (MASM or C++). For details, see [Numerical Expression Syntax](#).

Commands

Specifies one or more commands that will be executed repeatedly as long as the condition is true. This block of commands needs to be enclosed in braces, even if it consists of a single command. Multiple commands should be separated by semicolons, but the final command before the closing brace does not need to be followed by a semicolon.

Additional Information

For information about other control flow tokens and their use in debugger command programs, see [Using Debugger Command Programs](#).

Remarks

The **.break** and **.continue** tokens can be used to exit or restart the *Commands* block.

[Send comments about this topic to Microsoft](#)

Commands

5/26/2017 • 1 min to read • [Edit Online](#)

This section of the reference discusses the various debugger commands that you can use in CDB, KD, and WinDbg.

[Send comments about this topic to Microsoft](#)

ENTER (Repeat Last Command)

5/31/2017 • 1 min to read • [Edit Online](#)

The ENTER key repeats the last command that you typed.

ENTER

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

In CDB and KD, pressing the ENTER key by itself at a command prompt reissues the command that you previously entered.

In WinDbg, the ENTER key can have no effect or you can use it to repeat the previous command. You can set this option in the **Options** dialog box. (To open the **Options** dialog box, click **Options** on the **View** menu or click the **Options** button () on the toolbar.)

If you set ENTER to repeat the last command, but you want to create white space in the [Debugger Command window](#), use the *** (Comment Line Specifier)** token and then press ENTER several times.

[Send comments about this topic to Microsoft](#)

\$<, \$><, \$\$<, \$\$><, \$\$>a< (Run Script File)

5/31/2017 • 4 min to read • [Edit Online](#)

The `$<, $><, $$<, $$><, $$>a<` commands read the contents of the specified script file and use its contents as debugger command input.

```
$<Filename
$><Filename
$$<Filename
$$><Filename
$$>a<Filename [arg1 arg2 arg3 ...]
```

Parameters

Filename

Specifies a file that contains valid debugger command text. The file name must follow Microsoft Windows file name conventions. The file name may contain spaces.

argn

Specifies any number of string arguments for the debugger to pass to the script. The debugger will replace any string of the form `${$argn}` in the script file with the corresponding *argn* before executing the script. Arguments may not contain quotation marks or semicolons. Multiple arguments must be separated by spaces; if an argument contains a space it must be enclosed in quotation marks. All arguments are optional.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The `$$<` and `$<` tokens execute the commands that are found in the script file literally. However, with `$<` you can specify any file name, including one that contains semicolons. Because `$<` allows semicolons to be used in the file name, you cannot concatenate `$<` with other debugger commands, because a semicolon cannot be used both as a command separator and as part of a file name.

The `$$><` and `$><` tokens execute the commands that are found in the script file literally, which means they open the script file, replace all carriage returns with semicolons, and execute the resulting text as a single command block. As with `$<` discussed previously, the `$><` variation permits file names that contain semicolons, which means you cannot concatenate `$><` with other debugger commands.

The `$$><` and `$><` tokens are useful if you are running scripts that contain debugger command programs. For more information about these programs, see [Using Debugger Command Programs](#).

Unless you have file names that contain semicolons, you do not need to use either `$<` or `$><`.

The **\$\$>a<** token allows the debugger to pass arguments to the script. If *Filename* contains spaces, it must be enclosed in quotation marks. If too many arguments are supplied, the excess arguments are ignored. If too few arguments are supplied, any token in the source file of the form **\$\$argn** where *n* is larger than the number of supplied arguments will remain in its literal form and will not be replaced with anything. You can follow this command with a semicolon and additional commands; the presence of a semicolon terminates the argument list.

When the debugger executes a script file, the commands and their output are displayed in the [Debugger Command window](#). When the end of the script file is reached, control returns to the debugger.

The following table summarizes how you can use these tokens.

TOKEN	ALLOWS FILE NAMES THAT CONTAIN SEMICOLONS	ALLOWS CONCATENATION OF ADDITIONAL COMMANDS SEPARATED BY SEMICOLONS	CONDENSES TO SINGLE COMMAND BLOCK	ALLOWS SCRIPT ARGUMENTS
\$<	Yes	No	No	No
\$><	Yes	No	Yes	No
\$\$<	No	Yes	No	No
\$\$><	No	Yes	Yes	No
\$\$>a<	No	Yes	Yes	Yes

The **\$<**, **\$><**, **\$\$<**, and **\$\$><** commands echo the commands contained in the script file and display the output of these commands. The **\$\$>a<** command does not echo the commands found in the script file, but merely displays their output.

Script files can be nested. If the debugger encounters one of these tokens in a script file, execution moves to the new script file and returns to the previous location when the new script file has been completed. Scripts can also be called recursively.

In WinDbg, you can paste the additional command text in the Debugger Command window.

Examples

The following example demonstrates how to pass arguments to a script file, Myfile.txt. Assume that the file contains the following text:

```
.echo The first argument is $$arg1.
.echo The second argument is $$arg2.
```

Then you can pass arguments to this file by using a command like this:

```
0:000> $$>a<myfile.txt myFirstArg mySecondArg
```

The result of this command would be:

```
The first argument is myFirstArg.  
The second argument is mySecondArg.
```

Here is an example of what happens when the wrong number of argument is supplied. Assume that the file My Script.txt contains the following text:

```
.echo The first argument is ${arg1}.\n.echo The fifth argument is ${arg5}.\n.echo The fourth argument is ${arg4}.
```

Then the following semicolon-delimited command line produces output thus:

```
0:000> $$>a< "c:\bin1\my script.txt" "First one" Two "Three More" Four; recx  
The first argument is First one.  
The fifth argument is ${arg5}.\n.The fourth argument is Four.  
ecx=0021f4ac
```

In the preceding example, the file name is enclosed in quotation marks because it contains a space, and arguments that contain spaces are enclosed in quotation marks as well. Although a fifth argument seems to be expected by the script, the semicolon terminates the **\$\$>a<** command after the fourth argument.

[Send comments about this topic to Microsoft](#)

? (Command Help)

6/1/2017 • 1 min to read • [Edit Online](#)

The question mark (?) character displays a list of all commands and operators.

Note A question mark by itself displays command help. The **? expression** syntax evaluates the given expression.

```
?
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

For more information about standard commands, use **?**. For more information about meta-commands, use **.help**.
For more information about extension commands, use **!help**.

[Send comments about this topic to Microsoft](#)

?(Evaluate Expression)

6/1/2017 • 1 min to read • [Edit Online](#)

The question mark (?) command evaluates and displays the value of an expression.

Note A question mark by itself (?) displays command help. The ? *expression* command evaluates the given expression.

```
? Expression
```

Parameters

Expression

Specifies the expression to evaluate.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The input and output of the ? command depend on whether you are using MASM expression syntax or C++ expression syntax. For more information about these kinds of expression syntax, see [Evaluating Expressions](#) and [Numerical Expression Syntax](#).

If you are using MASM syntax, the input and output depend on the current radix. To change the radix, use the **n** ([Set Number Base](#)) command.

The ? command evaluates symbols in the expression in the context of the current thread and process.

Some strings may contain escapes, such as **\n**, **\"**, **\r**, and **\b**, that are meant to be read literally, rather than interpreted by the evaluator. If an escape within a string is interpreted by the evaluator, errors in evaluation can occur. For example:

```
0:000> as AliasName c:\dir\name.txt
0:000> al
  Alias      Value
  -----
  AliasName    c:\dir\name.txt
0:001> ? $pat( "c:\dir\name.txt", "*name*" )
Evaluate expression: 0 = 00000000
0:001> ? ${AliasName}", "*name*" )
Evaluate expression: 0 = 00000000
0:001> ? $pat( "c:\dir\", "*filename*" )
Syntax error at 'c:\dir\", "*filename*")
```

In the first two examples, even though the string does match the pattern, the evaluator is returning a value of **FALSE**. In the third, the evaluator cannot make a comparison because the string ends in a backslash (\), and so the \" is translated by the evaluator.

To get the evaluator to interpret a string literally, you must use the `@"String"` syntax. The following code example shows the correct results:

```
0:000> ? $spat( @"c:\dir\name.txt", "*name*" )
Evaluate expression: 1 = 00000000`00000001
0:000> ? $spat( @"${AliasName}", "*name*" )
Evaluate expression: 1 = 00000000`00000001
0:001> ? $spat( @"c:\dir\" , "*filename*" )
Evaluate expression: 0 = 00000000
```

In the preceding examples, the **\$spat** MASM operator checks the first string to determine whether it matches (case-insensitive) the pattern of the second string. For more information about MASM operators, see the [MASM Numbers and Operators](#) topic.

[?? \(Evaluate C++ Expression\)](#)

[.formats \(Show Number Formats\)](#)

[Send comments about this topic to Microsoft](#)

?? (Evaluate C++ Expression)

5/31/2017 • 1 min to read • [Edit Online](#)

The double question mark (??) command evaluates and displays the value of an expression according to C++ expression rules.

```
?? Expression
```

Parameters

Expression

Specifies the C++ expression to evaluate. For more information about the syntax, see [C++ Numbers and Operators](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The ?? command evaluates symbols in the expression in the context of the current thread and process.

If you want to evaluate a part of the **Expression** expression according to MASM expression rules, enclose that part in parentheses and add two at signs (@@) before it. For more information about MASM expressions and C++ expressions, see [Evaluating Expressions](#) and [Numerical Expression Syntax](#).

[? \(Evaluate Expression\)](#)

[.formats \(Show Number Formats\)](#)

[Send comments about this topic to Microsoft](#)

(Search for Disassembly Pattern)

5/31/2017 • 2 min to read • [Edit Online](#)

The number sign (#) command searches for the specified pattern in the disassembly code.

```
# [Pattern] [Address [ L Size ]]
```

Parameters

Pattern

Specifies the pattern to search for in the disassembly code. *Pattern* can contain a variety of wildcard characters and specifiers. For more information about the syntax, see [String Wildcard Syntax](#). If you want to include spaces in *Pattern*, you must enclose the pattern in quotation marks. The pattern is not case sensitive. If you have previously used the # command and you omit *Pattern*, the command reuses the most recently used pattern.

Address

Specifies the address where the search begins. For more information about the syntax, see [Address and Address Range Syntax](#).

Size

Specifies the number of instructions to search. If you omit *Size*, the search continues until the first match occurs.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about assembly debugging and related commands, see [Debugging in Assembly Mode](#).

Remarks

If you previously used the # command and you omit *Address*, the search begins where the previous search ended.

This command works by searching the disassembled text for the specified pattern. You can use this command to find register names, constants, or any other string that appears in the disassembly output. You can repeat the command without the *Address* parameter to find successive occurrences of the pattern.

You can view disassembly instructions by using the **u (Unassemble)** command or by using the [Disassembly window](#) in WinDbg. The disassembly display contains up to four parts: Address offset, Binary code, Assembly language mnemonic, and Assembly language details. The following example shows a possible display.

```
0040116b 45          inc      ebp
0040116c fc          cld
0040116d 8945b0      mov      eax,[ebp-0x1c]
```

The **#** command can search for text within any single part of the disassembly display. For example, you could use **# eax 0040116b** to find the **mov eax,[ebp-0x1c]** instruction at address 0040116d. The following commands also find this instruction.

```
# [ebp?0x 0040116b
# mov 0040116b
# 8945* 0040116b
# 116d 0040116b
```

However, you cannot search for **mov eax*** as a single unit, because **mov** and **eax** appear in different parts of the display. Instead, use **mov*eax**.

As an additional example, you could issue the following command to search for the first reference to the **strlen** function after the entry point **main**.

```
# strlen main
```

Similarly, you could issue the following two commands to find the first **jnz** instruction after address 0x779F9FBA and then find the next **jnz** instruction after that.

```
# jnz 779f9fba#
```

When you omit *Pattern* or *Address*, their values are based on the previous use of the **#** command. If you omit either parameter the first time that you issue the **#** command, no search is performed. However, the values of *Pattern* and *Address* are initialized even in this situation.

If you include *Pattern* or *Address*, its value is set to the entered value. If you omit *Address*, it is initialized to the current value of the program counter. If you omit *Pattern*, it is initialized to an empty pattern.

[Send comments about this topic to Microsoft](#)

|| (System Status)

5/31/2017 • 1 min to read • [Edit Online](#)

The double vertical bar (||) command prints status for the specified system or for all systems that you are currently debugging.

Do not confuse this command with the [| \(Process Status\)](#) command.

```
|| System
```

Parameters

System

Specifies the system to display. If you omit this parameter, all systems that you are debugging are displayed. For more information about the syntax, see [System Syntax](#).

Environment

Modes	Multiple target debugging
Targets	Live, crash dump
Platforms	All

Remarks

The || command is useful only when you are debugging multiple targets. Many, but not all, multiple-target debugging sessions involve multiple systems. For more information about these sessions, see [Debugging Multiple Targets](#).

Each system listing includes the server name and the protocol details. The system that the debugger is running on is identified as **<Local>**.

The following examples show you how to use this command. The following command displays all systems.

```
3:2:005> ||
```

The following command also displays all systems.

```
3:2:005> ||*
```

The following command displays the currently active system.

```
3:2:005> ||.
```

The following command displays the system that had the most recent exception or break.

```
3:2:005> ||#
```

The following command displays system number 2.

```
3:2:005> ||2
```

[Send comments about this topic to Microsoft](#)

||s (Set Current System)

5/31/2017 • 1 min to read • [Edit Online](#)

The **||s** command sets or displays the current system number.

Do not confuse this command with the **s (Search Memory)**, **~s (Change Current Processor)**, **~s (Set Current Thread)**, or **|s (Set Current Process)** command.

```
||System s
|| s
```

Parameters

System

Specifies the system to activate. For more information about the syntax, see [System Syntax](#).

Environment

Modes	Multiple target debugging
Targets	Live, crash dump
Platforms	All

Remarks

The **||s** command is useful only when you are debugging multiple targets. Many, but not all, multiple-target debugging sessions involve multiple systems. For more information about these kinds of sessions, see [Debugging Multiple Targets](#).

If you use the **||s** syntax, the debugger displays information about the current system.

This command also disassembles the current instruction for the current system, process, and thread.

[Send comments about this topic to Microsoft](#)

| (Process Status)

5/31/2017 • 1 min to read • [Edit Online](#)

The pipe (|) command displays status for the specified process, or for all processes that you are currently debugging.

Do not confuse this command with the [|| \(System Status\)](#) command.

| Process

Parameters

Process

Specifies the process to display. If you omit this parameter, all processes that you are debugging are displayed. For more information about the syntax, see [Process Syntax](#).

Environment

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information and other methods of displaying or controlling processes and threads, see [Controlling Processes and Threads](#).

Remarks

You can specify processes only in user mode.

You can add a process symbol before many commands. For more information about the meaning of a pipe (|) followed by a command, see the entry for the command itself.

Unless you enabled the debugging of child processes when you started the debugging session, there is only one process that is available to the debugger.

The following examples show you how to use this command. The following command displays all processes.

```
2:005> |
```

The following command also displays all processes.

```
2:005> |*
```

The following command displays the currently active process.

```
2:005> |.
```

The following command displays the process that originally caused the exception (or that the debugger originally attached to).

```
2:005> |#
```

The following command displays process number 2.

```
2:005> |2
```

The previous command displays the following output.

```
0:002> |
# 0 id: 224  name: myprog.exe
  1 id: 228  name: onechild.exe
. 2 id: 22c  name: anotherchild.exe
```

On the first line of this output, 0 is the decimal process number, 224 is the hexadecimal process ID, and *Myprog.exe* is the application name of the process. The period (.) before process 2 means that this process is the current process. The number sign (#) before process 0 means that this process was the one that originally caused the exception or that the debugger attached to.

[Send comments about this topic to Microsoft](#)

|s (Set Current Process)

5/31/2017 • 1 min to read • [Edit Online](#)

The **|s** command sets or displays the current process number.

Do not confuse this command with the **s (Search Memory)**, **~s (Change Current Processor)**, **~s (Set Current Thread)**, or **||s (Set Current System)** command.

```
|Process s
| s
```

Parameters

Process

Specifies the process to set or display. For more information about the syntax, see [Process Syntax](#).

Environment

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about other methods of displaying or controlling processes and threads, see [Controlling Processes and Threads](#).

Remarks

You can specify processes only in user mode.

If you use the **|s** syntax, the debugger displays information about the current process.

This command also disassembles the current instruction for the current system, process, and thread.

[Send comments about this topic to Microsoft](#)

~ (Thread Status)

5/31/2017 • 1 min to read • [Edit Online](#)

The tilde (~) command displays status for the specified thread or for all threads in the current process.

~ Thread

Parameters

Thread

Specifies the thread to display. If you omit this parameter, all threads are displayed. For more information about the syntax, see [Thread Syntax](#).

Environment

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information and other methods of displaying or controlling processes and threads, see [Controlling Processes and Threads](#).

Remarks

You can specify threads only in user mode. In kernel mode, the tilde (~) refers to a processor.

You can add a thread symbol before many commands. For more information about the meaning of a tilde (~) followed by a command, see the entry for the command itself.

The following examples show you how to use this command. The following command displays all threads.

```
0:001> ~
```

The following command also displays all threads.

```
0:001> ~*
```

The following command displays the currently active thread.

```
0:001> ~.
```

The following command displays the thread that originally caused the exception (or that was active when the debugger attached to the process).

```
0:001> ~#
```

The following command displays thread number 2.

```
0:001> ~2
```

The previous command displays the following output.

```
0:001> ~
  0 id: 4dc.470 Suspend: 0 Teb 7ffde000 Unfrozen
  . 1 id: 4dc.534 Suspend: 0 Teb 7ffdd000 Unfrozen
#  2 id: 4dc.5a8 Suspend: 0 Teb 7ffdc000 Unfrozen
```

On the first line of this output, 0 is the decimal thread number, 4DC is the hexadecimal process ID, 470 is the hexadecimal thread ID, 0x7FFDE000 is the address of the TEB, and **Unfrozen** is the thread status. The period (.) before thread 1 means this thread is the current thread. The number sign (#) before thread 2 means this thread was the one that originally caused the exception or it was active when the debugger attached to the process.

[Send comments about this topic to Microsoft](#)

~e (Thread-Specific Command)

5/31/2017 • 1 min to read • [Edit Online](#)

The **~e** command executes one or more commands for a specific thread or for all threads in the target process.

Do not confuse this command with the **e (Enter Values)** command.

```
~Thread e CommandString
```

Parameters

Thread

Specifies the thread or threads that the debugger will execute *CommandString* for. For more information about the syntax, see [Thread Syntax](#).

CommandString

Specifies one or more commands to execute. You should separate multiple commands by using semicolons.

CommandString includes the rest of the input line. All of the text that follows the letter "e" is interpreted as part of this string. Do not enclose *CommandString* in quotation marks.

Environment

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about other commands that control threads, see [Controlling Processes and Threads](#).

Remarks

You can specify threads only in user mode. In kernel mode, the tilde (~) refers to a processor.

When you use the **~e** command together with one thread, the **~e** command only saves some typing. For example, the following two commands are equivalent.

```
0:000> ~2e r; k; kd  
0:000> ~2r; ~2k; ~2kd
```

However, you can use the **~e** qualifier to repeat a command or extension command several times. When you use the qualifier in this manner, it can eliminate extra typing. For example, the following command repeats the **!gle** extension command for every thread that you are debugging.

```
0:000> ~*e !gle
```

If an error occurs in the execution of one command, execution continues with the next command.

You cannot use the **~e** qualifier together with execution commands (**g**, **gh**, **gn**, **gN**, **gu**, **p**, **pa**, **pc**, **t**, **ta**, **tb**, **tc**, **wt**).

You cannot use the **~e** qualifier together with the **j (Execute If-Else)** or **z (Execute While)** conditional commands.

If you are debugging more than one process, you cannot use the **~e** command to access the virtual memory space for a inactive process.

[Send comments about this topic to Microsoft](#)

~f (Freeze Thread)

5/31/2017 • 1 min to read • [Edit Online](#)

The **~f** command freezes the given thread, causing it to stop and wait until it is unfrozen.

Do not confuse this command with the **f (Fill Memory)** command.

```
~Thread f
```

Parameters

Thread

Specifies the thread to freeze. For more information about the syntax, see [Thread Syntax](#).

Environment

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how frozen threads behave and a list of other commands that control the freezing and suspending of threads, see [Controlling Processes and Threads](#).

Remarks

You can specify threads only in user mode. In kernel mode, the tilde (~) refers to a processor.

The **~f** command causes the specified thread to freeze. When the debugger enables the target application to resume execution, other threads execute as expected while this thread remains stopped.

The following examples show you how to use this command. The following command displays the current status of all threads.

```
0:000> ~* k
```

The following command freezes the thread that caused the current exception.

```
0:000> ~# f
```

The following command checks that the status of this thread is suspended.

```
0:000> ~* k
```

The following command unfreezes thread number 123.

```
0:000> ~123 u
```

[Send comments about this topic to Microsoft](#)

~u (Unfreeze Thread)

5/31/2017 • 1 min to read • [Edit Online](#)

The **~u** command unfreezes the specified thread.

Do not confuse this command with the **U (Unassemble)** command.

```
~Thread u
```

Parameters

Thread

Specifies the thread or threads to unfreeze. For more information about the syntax, see [Thread Syntax](#).

Environment

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how frozen threads behave and a list of other commands that control the freezing and suspending of threads, see [Controlling Processes and Threads](#).

Remarks

You can specify threads only in user mode. In kernel mode, the tilde (~) refers to a processor.

The following examples show you how to use the ~ commands.

The following command displays the current status of all threads.

```
0:000> ~* k
```

The following command freeze the thread that caused the current exception.

```
0:000> ~# f
```

The following command checks that the status of this thread is suspended.

```
0:000> ~* k
```

The following command unfreezes thread number 123.

0:000> ~123 u

[Send comments about this topic to Microsoft](#)

~n (Suspend Thread)

5/31/2017 • 1 min to read • [Edit Online](#)

The **~n** command suspends execution of the specified thread.

Do not confuse this command with the **n (Set Number Base)** command.

```
~Thread n
```

Parameters

Thread

Specifies the thread or threads to suspend. For more information about the syntax, see [Thread Syntax](#).

Environment

Modes	User mode only
Targets	Live debugging only
Platforms	All

Additional Information

For more information about the suspend count and how suspended threads behave and for a list of other commands that control the suspending and freezing of threads, see [Controlling Processes and Threads](#).

Remarks

You can specify threads only in user mode. In kernel mode, the tilde (~) refers to a processor.

Every time that you use the **~n** command, the thread's suspend count is increased by one.

The thread's start address is displayed when you use this command.

[Send comments about this topic to Microsoft](#)

~m (Resume Thread)

5/31/2017 • 1 min to read • [Edit Online](#)

The **~m** command resumes execution of the specified thread.

Do not confuse this command with the **m (Move Memory)** command.

```
~Thread m
```

Parameters

Thread

Specifies the thread or threads to resume. For more information about the syntax, see [Thread Syntax](#).

Environment

Modes	User mode only
Targets	Live debugging only
Platforms	All

Additional Information

For more information about the suspend count and how suspended threads behave and for a list of other commands that control the suspending and freezing of threads, see [Controlling Processes and Threads](#).

Remarks

You can specify threads only in user mode. In kernel mode, the tilde (~) refers to a processor.

Every time that you use the **~m** command, the thread's suspend count is decreased by one.

[Send comments about this topic to Microsoft](#)

~s (Set Current Thread)

5/31/2017 • 1 min to read • [Edit Online](#)

The **~s** command sets or displays the current thread number.

In user mode, **~s** sets the current thread. Do not confuse this command confused with the [~s \(Change Current Processor\)](#) command (which works only in kernel mode), the [!s \(Set Current Process\)](#) command, the [||s \(Set Current System\)](#) command, or the [s \(Search Memory\)](#) command.

```
~Thread s
~ s
```

Parameters

Thread

Specifies the thread to set or display. For more information about the syntax, see [Thread Syntax](#).

Environment

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information and other methods of displaying or controlling processes and threads, see [Controlling Processes and Threads](#).

Remarks

You can specify threads only in user mode. In kernel mode, the tilde (~) refers to a processor.

If you use the **~s** syntax, the debugger displays information about the current thread.

This command also disassembles the current instruction for the current system, process, and thread.

[Send comments about this topic to Microsoft](#)

~s (Change Current Processor)

5/31/2017 • 1 min to read • [Edit Online](#)

The **~s** command sets which processor is debugged on a multiprocessor system.

In kernel mode, **~s** changes the current processor. Do not confuse this command with the **~s (Set Current Thread)** command (which works only in user mode), the **|s (Set Current Process)** command, the **||s (Set Current System)** command, or the **s (Search Memory)** command.

```
~Processor s
```

Parameters

Processor

Specifies the number of the processor to debug.

Environment

Modes	Kernel mode only
Targets	Live, crash dump
Platforms	All

Remarks

You can specify processors only in kernel mode. In user mode, the tilde (~) refers to a thread.

You can immediately tell when you are working on a multiple processor system by the shape of the kernel debugging prompt. In the following example, 0: means that you are debugging the first processor in the computer.

```
0: kd>
```

Use the following command to switch between processors:

```
0: kd> ~1s
1: kd>
```

Now the second processor in the computer that is being debugged.

See also

[Multiprocessor Syntax](#)

[Send comments about this topic to Microsoft](#)

a (Assemble)

5/31/2017 • 1 min to read • [Edit Online](#)

The **a** command assembles 32-bit x86 instruction mnemonics and puts the resulting instruction codes into memory.

```
a [Address]
```

Parameters

Address

Specifies the beginning of the block in memory where the resulting codes are put. For more information about the syntax, see [Address and Address Range Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about assembly debugging and related commands, see [Debugging in Assembly Mode](#).

Remarks

The **a** command does not support 64-bit instruction mnemonics. However, the **a** command is enabled regardless of whether you are debugging a 32-bit target or a 64-bit target. Because of the similarities between x86 and x64 instructions, you can sometimes use the **a** command successfully when debugging a 64-bit target.

If you do not specify an address, the assembly starts at the address that the current value of the instruction pointer specifies. To assemble a new instruction, type the desired mnemonic and press ENTER. To end assembly, press only ENTER.

Because the assembler searches for all of the symbols that are referred to in the code, this command might take time to complete. During this time, you cannot press **CTRL+C** to end the **a** command.

[Send comments about this topic to Microsoft](#)

ad (Delete Alias)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ad** command deletes an alias from the alias list.

```
ad [/q] Name
ad *
```

Parameters

/q

Specifies quiet mode. This mode hides the error message if the alias that *Name* specifies does not exist.

Name

Specifies the name of the alias to delete. If you specify an asterisk (*), all aliases are deleted (even if there is an alias whose name is "*").

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how to use aliases, see [Using Aliases](#).

Remarks

You can use the **ad** command to delete any user-named alias. But you cannot use this command to delete a fixed-name alias (\$u0 to \$u9).

[Send comments about this topic to Microsoft](#)

ah (Assertion Handling)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ah** command controls the assertion handling status for specific addresses.

```
ahb [Address]
ahi [Address]
ahd [Address]
ahc
ah
```

Parameters

ahb

Breaks into the debugger if an assertion fails at the specified address.

ahi

Ignores an assertion failure at the specified address.

ahd

Deletes any assertion-handling information at the specified address. This deletion causes the debugger to return to its default state for that address.

Address

Specifies the address of the instruction whose assertion-handling status is being set. If you omit this parameter, the debugger uses the current program counter.

ahc

Deletes all assertion-handling information for the current process.

ah

Displays the current assertion-handling settings.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about break status and handling status, descriptions of all event codes, a list of the default status for all events, and details about other methods of controlling this status, see [Controlling Exceptions and Events](#).

Remarks

The **ah*** command controls the assertion handling status for a specific address. The **sx* asrt** command controls the global assertion handling status. If you use **ah*** for a certain address and then an assert occurs there, the

debugger responds based on the **ah*** settings and ignores the **sx* asrt** settings.

When the debugger encounters an assertion, the debugger first checks whether handling has been configured for that specific address. If you have not configured the handling, the debugger uses the global setting.

The **ah*** command affects only the current process. When the current process ends, all status settings are lost.

Assertion handling status affects only STATUS_ASSERTION_EXCEPTION exceptions. This handling does not affect the kernel-mode ASSERT routine.

[Send comments about this topic to Microsoft](#)

al (List Aliases)

5/31/2017 • 1 min to read • [Edit Online](#)

The **al** command displays a list of all currently defined user-named aliases.

```
al
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how to use aliases, see [Using Aliases](#).

Remarks

The **al** command lists all user-named aliases. But this command does not list fixed-name aliases (\$u0 to \$u9).

[Send comments about this topic to Microsoft](#)

as, aS (Set Alias)

5/31/2017 • 4 min to read • [Edit Online](#)

The **as** and **aS** commands define a new alias or redefine an existing one.

```
as Name EquivalentLine
aS Name EquivalentPhrase
aS Name "EquivalentPhrase"
as /e Name EnvironmentVariable
as /ma Name Address
as /mu Name Address
as /msa Name Address
as /msu Name Address
as /x Name Expression
aS /f Name File
as /c Name CommandString
```

Parameters

Name

Specifies the alias name. This name can be any text string that does not contain a space or the ENTER keystroke and does not begin with "al", "as", "aS", or "ad". *Name* is case sensitive.

EquivalentLine

Specifies the alias equivalent. *EquivalentLine* is case sensitive. You must add at least one space between *Name* and *EquivalentLine*. The number of spaces between these two parameters is not important. The alias equivalent never contains leading spaces. After these spaces, *EquivalentLine* includes the rest of the line. Semicolons, quotation marks, and spaces are treated as literal characters, and trailing spaces are included.

EquivalentPhrase

Specifies the alias equivalent. *EquivalentPhrase* is case sensitive. You must add at least one space between *Name* and *EquivalentPhrase*. The number of spaces between these two parameters is not important. The alias equivalent never contains leading spaces.

You can enclose *EquivalentPhrase* in quotation marks (""). Regardless of whether you use quotation marks, *EquivalentPhrase* can contain spaces, commas, and single quotation marks (''). If you enclose *EquivalentPhrase* in quotation marks, it can include semicolons, but not additional quotation marks. If you do not enclose *EquivalentPhrase* in quotation marks, it can include quotation marks in any location other than the first character, but it cannot include semicolons. Trailing spaces are included regardless of whether you use quotation marks.

/e

Sets the alias equivalent equal to the environment variable that *EnvironmentVariable* specifies.

EnvironmentVariable

Specifies the environment variable that is used to determine the alias equivalent. The debugger's environment is used, not the target's. If you started the debugger at a Command Prompt window, the environment variables in that window are used.

/ma

Sets the alias equivalent equal to the null-terminated ASCII string that begins at *Address*.

/mu

Sets the alias equivalent equal to the null-terminated Unicode string that begins at *Address*.

/msa

Sets the alias equivalent equal to the ANSI_STRING structure that is located at *Address*.

/msu

Sets the alias equivalent equal to the UNICODE_STRING structure that is located at *Address*.

Address

Specifies the location of the virtual memory that is used to determine the alias equivalent.

/x

Sets the alias equivalent equal to the 64-bit value of *Expression*.

Expression

Specifies the expression to evaluate. This value becomes the alias equivalent. For more information about the syntax, see [Numerical Expression Syntax](#).

/f

Sets the alias equivalent equal to the contents of the *File* file. You should always use the **/f** switch together with **as**, not with **as**.

File

Specifies the file whose contents become the alias equivalent. *File* can contain spaces, but you should never enclose *File* in quotation marks. If you specify an invalid file, you receive an "Out of memory" error message.

/c

Sets the alias equivalent equal to the output of the commands that *CommandString* specifies. The alias equivalent includes carriage returns if they are present within the command display and a carriage return at the end of the display of each command (even if you specify only one command).

CommandString

Specifies the commands whose outputs become the alias equivalent. This string can include any number of commands that are separated by semicolons.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how to use aliases, see [Using Aliases](#).

Remarks

If you do not use any switches, the **as** command uses the rest of the line as the alias equivalent.

You can end the **as** command by a semicolon. This technique is useful in a script when you have to put all commands on a single line. Note that if the portion of the line after the semicolon requires expansion of the alias, you must enclose that second portion of the line in a new block. The following example produces the expected output, 0x6.

```
0:001> aS /x myAlias 5 + 1; .block{.echo myAlias}  
0x6
```

If you omit the new block, you do not get the expected output. That is because the expansion of a newly set alias does not happen until a new code block is entered. In the following example, the new block is omitted, and the output is the text "myAlias" instead of the expected value 0x6.

```
0:001> aS /x myAlias 5 + 1; .echo myAlias  
myAlias
```

For more information about using aliases in scripts, see [Using Aliases](#).

If you use a **/e**, **/ma**, **/mu**, **/msa**, **/msu**, or **/x** switch, the **as** and **aS** commands work the same and the command ends if a semicolon is encountered.

If *Name* is already the name of an existing alias, that alias is redefined.

You can use the **as** or **aS** command to create or change any user-named alias. But you cannot use the command to control a fixed-name alias (\$u0 to \$u9).

You can use the **/ma**, **/mu**, **/msa**, **/msu**, **/f**, and **/c** switches to create an alias that contains carriage returns. However, you cannot use an alias that contains carriage returns to execute multiple commands in sequence. Instead, you must use semicolons.

[Send comments about this topic to Microsoft](#)

ba (Break on Access)

5/31/2017 • 6 min to read • [Edit Online](#)

The **ba** command sets a processor breakpoint (often called, less accurately, a *data breakpoint*). This breakpoint is triggered when the specified memory is accessed.

User-Mode

```
[~Thread] ba[ID] Access Size [Options] [Address [Passes]] ["CommandString"]
```

Kernel-Mode

```
ba[ID] Access Size [Options] [Address [Passes]] ["CommandString"]
```

Parameters

Thread

Specifies the thread that the breakpoint applies to. For more information about syntax, see [Thread Syntax](#). You can specify threads only in user mode.

ID

Specifies an optional number that identifies the breakpoint. If you do not specify *ID*, the first available breakpoint number is used. You cannot add space between **ba** and the ID number. Each processor supports only a limited number of processor breakpoints, but there is no restriction on the value of the *ID* number. If you enclose *ID* in square brackets ([]), *ID* can include any expression. For more information about the syntax, see [Numerical Expression Syntax](#).

Access

Specifies the type of access that satisfies the breakpoint. This parameter can be one of the following values.

OPTION	ACTION
e (execute)	Breaks into the debugger when the CPU retrieves an instruction from the specified address.
r (read/write)	Breaks into the debugger when the CPU reads or writes at the specified address.
w (write)	Breaks into the debugger when the CPU writes at the specified address.
i (i/o)	(Microsoft Windows XP and later versions, kernel mode only, x86-based systems only) Breaks into the debugger when the I/O port at the specified <i>Address</i> is accessed.

Size

Specifies the size of the location, in bytes, to monitor for access. On an x86-based processor, this parameter can

be 1, 2, or 4. However, if *Access* equals **e**, *Size* must be 1.

On an x64-based processor, this parameter can be 1, 2, 4, or 8. However, if *Access* equals **e**, *Size* must be 1.

Options

Specifies breakpoint options. You can use any number of the following options, except as indicated:

/1

Creates a "one-shot" breakpoint. After this breakpoint is triggered, the breakpoint is permanently removed from the breakpoint list.

/p EProcess

(Kernel mode only) Specifies a process that is associated with this breakpoint. *EProcess* should be the actual address of the EPROCESS structure, not the PID. The breakpoint is triggered only if it is encountered in the context of this process.

/t EThread

(Kernel mode only) Specifies a thread that is associated with this breakpoint. *EThread* should be the actual address of theETHREAD structure, not the thread ID. The breakpoint is triggered only if it is encountered in the context of this thread. If you use **/p EProcess** and **/t EThread**, you can enter them in either order.

/c MaxCallStackDepth

Causes the breakpoint to be active only when the call stack depth is less than *MaxCallStackDepth*. You cannot combine this option together with **/C**.

/C MinCallStackDepth

Causes the breakpoint to be active only when the call stack depth is larger than *MinCallStackDepth*. You cannot combine this option together with **/c**.

Address

Specifies any valid address. If the application accesses memory at this address, the debugger stops execution and displays the current values of all registers and flags. This address must be an offset and suitably aligned to match the *Size* parameter. (For example, if *Size* is 4, *Address* must be a multiple of 4.) If you omit *Address*, the current instruction pointer is used. For more information about the syntax, see [Address and Address Range Syntax](#).

Passes

Specifies the number of times the breakpoint is passed by until it activates. This number can be any 16-bit value. The number of times the program counter passes through this point without breaking is one less than the value of this number. Therefore, omitting this number is the same as setting it equal to 1. Note also that this number counts only the times that the application *executes* past this point. Stepping or tracing past this point does not count. After the full count is reached, you can reset this number only by clearing and resetting the breakpoint.

CommandString

Specifies a list of commands to execute every time that the breakpoint is encountered the specified number of times. These commands are executed only if the breakpoint is hit after you issue a **g (Go)** command, instead of after a **t (Trace)** or **p (Step)** command. Debugger commands in *CommandString* can include parameters.

You must enclose this command string in quotation marks, and you should separate multiple commands by semicolons. You can use standard C control characters (such as **\n** and **\\"**). Semicolons that are contained in second-level quotation marks (**\\"**) are interpreted as part of the embedded quoted string.

This parameter is optional.

Environment

Modes	User mode, kernel mode
-------	------------------------

Targets	Live debugging only
Platforms	All

Additional Information

For more information on processor breakpoints, see [Processor Breakpoints \(ba Breakpoints\)](#). For more information about and examples of using breakpoints, other breakpoint commands and methods of controlling breakpoints, and information about how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

The debugger uses the *ID* number to refer to the breakpoint in later [bc \(Breakpoint Clear\)](#), [bd \(Breakpoint Disable\)](#), and [be \(Breakpoint Enable\)](#) commands.

Use the [bl \(Breakpoint List\)](#) command to list all existing breakpoints, their ID numbers, and their status.

Use the [.bpcmds \(Display Breakpoint Commands\)](#) command to list all existing breakpoints, their ID numbers, and the commands that were used to create them.

Each processor breakpoint has a size associated with it. For example, a **w** (write) processor breakpoint could be set at the address 0x70001008 with a size of four bytes. This would monitor the block of addresses from 0x70001008 to 0x7000100B, inclusive. If this block of memory is written to, the breakpoint will be triggered.

It can happen that the processor performs an operation on a memory region that *overlaps* with, but is not identical to, the specified region. In this example, a single write operation that includes the range 0x70001000 to 0x7000100F, or a write operation that includes only the byte at 0x70001009, would be an overlapping operation. In such a situation, whether the breakpoint is triggered is processor-dependent. You should consult the processor manual for specific details. To take one specific instance, on an x86 processor, a read or write breakpoint is triggered whenever the accessed range overlaps the breakpoint range.

Similarly, if an **e** (execute) breakpoint is set on the address 0x00401003, and then a two-byte instruction spanning the addresses 0x00401002 and 0x00401003 is executed, the result is processor-dependent. Again, consult the processor architecture manual for details.

The processor distinguishes between breakpoints set by a user-mode debugger and breakpoints set by a kernel-mode debugger. A user-mode processor breakpoint does not affect any kernel-mode processes. A kernel-mode processor breakpoint might or might not affect a user-mode process, depending on whether the user-mode code is using the debug register state and whether there is a user-mode debugger that is attached.

To apply the current process' existing data breakpoints to a different register context, use the [.apply_dbp \(Apply Data Breakpoint to Context\)](#) command.

On a multiprocessor computer, each processor breakpoint applies to all processors. For example, if the current processor is 3 and you use the command `ba e1 MyAddress` to put a breakpoint at MyAddress, any processor -- not only processor 3 -- that executes at that address triggers the breakpoint. (This holds for software breakpoints as well.)

You cannot create multiple processor breakpoints at the same address that differ only in their *CommandString* values. However, you can create multiple breakpoints at the same address that have different restrictions (for example, different values of the **/p**, **/t**, **/c**, and **/C** options).

For more details on processor breakpoints, and additional restrictions that apply to them, see [Processor Breakpoints \(ba Breakpoints\)](#).

The following examples show the **ba** command. The following command sets a breakpoint for read access on 4 bytes of the variable myVar.

```
0:000> ba r4 myVar
```

The following command adds a breakpoint on all serial ports with addresses from 0x3F8 through 0x3FB. This breakpoint is triggered if anything is read or written to these ports.

```
kd> ba i4 3f8
```

[Send comments about this topic to Microsoft](#)

bc (Breakpoint Clear)

5/31/2017 • 1 min to read • [Edit Online](#)

The **bc** command permanently removes previously set breakpoints from the system.

```
bc Breakpoints
```

Parameters

Breakpoints

Specifies the ID numbers of the breakpoints to remove. You can specify any number of breakpoints. You must separate multiple IDs by spaces or commas. You can specify a range of breakpoint IDs by using a hyphen (-). You can use an asterisk (*) to indicate all breakpoints. If you want to use a [numeric expression](#) for an ID, enclose it in brackets ([]). If you want to use a [string with wildcard characters](#) to match a breakpoint's symbolic name, enclose it in quotation marks (" ").

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

Use the [bl \(Breakpoint List\)](#) command to list all existing breakpoints, their ID numbers, and their status.

Use the [.bpcmds \(Display Breakpoint Commands\)](#) command to list all existing breakpoints, their ID numbers, and the commands that were used to create them.

[Send comments about this topic to Microsoft](#)

bd (Breakpoint Disable)

5/31/2017 • 1 min to read • [Edit Online](#)

The **bd** command disables, but does not delete, previously set breakpoints.

```
bd Breakpoints
```

Parameters

Breakpoints

Specifies the ID numbers of the breakpoints to disable. You can specify any number of breakpoints. You must separate multiple IDs by spaces or commas. You can specify a range of breakpoint IDs by using a hyphen (-). You can use an asterisk (*) to indicate all breakpoints. If you want to use a [numeric expression](#) for an ID, enclose it in brackets ([]). If you want to use a [string with wildcard characters](#) to match a breakpoint's symbolic name, enclose it in quotation marks ("").

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

When a breakpoint is disabled, the system does not check whether the conditions that are specified in the breakpoint are valid.

Use the [be \(Breakpoint Enable\)](#) command to re-enable a disabled breakpoint.

Use the [bl \(Breakpoint List\)](#) command to list all existing breakpoints, their ID numbers, and their status.

Use the [.bpcmds \(Display Breakpoint Commands\)](#) command to list all existing breakpoints, their ID numbers, and the commands that were used to create them.

[Send comments about this topic to Microsoft](#)

be (Breakpoint Enable)

5/31/2017 • 1 min to read • [Edit Online](#)

The **be** command restores one or more breakpoints that were previously disabled.

```
be Breakpoints
```

Parameters

Breakpoints

Specifies the ID numbers of the breakpoints to enable. You can specify any number of breakpoints. You must separate multiple IDs by spaces or commas. You can specify a range of breakpoint IDs by using a hyphen (-). You can use an asterisk (*) to indicate all breakpoints. If you want to use a [numeric expression](#) for an ID, enclose it in brackets ([]). If you want to use a [string with wildcard characters](#) to match a breakpoint's symbolic name, enclose it in quotation marks ("*").

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about and examples of how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

Use the [bl \(Breakpoint List\)](#) command to list all existing breakpoints, their ID numbers, and their status.

Use the [.bpcmds \(Display Breakpoint Commands\)](#) command to list all existing breakpoints, their ID numbers, and the commands that were used to create them.

[Send comments about this topic to Microsoft](#)

bl (Breakpoint List)

5/31/2017 • 3 min to read • [Edit Online](#)

The **bl** command lists information about existing breakpoints.

```
bl [/L] [Breakpoints]
```

Parameters

/L

Forces **bl** to always display breakpoint addresses instead of showing source file and line numbers.

Breakpoints

Specifies the ID numbers of the breakpoints to list. If you omit *Breakpoints*, the debugger lists all breakpoints. You can specify any number of breakpoints. You must separate multiple IDs by spaces or commas. You can specify a range of breakpoint IDs by using a hyphen (-). You can use an asterisk (*) to indicate all breakpoints. If you want to use a *numeric expression* for an ID, enclose it in brackets ([]). If you want to use a *string with wildcard characters* to match a breakpoint's symbolic name, enclose it in quotation marks ("**" **).

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about and examples of how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

For each breakpoint, the command displays the following information:

- The breakpoint ID. This ID is a decimal number that you can use to refer to the breakpoint in later commands.
- The breakpoint status. The status can be **e** (enabled) or **d** (disabled).
- (Unresolved breakpoints only) The letter "u" appears if the breakpoint is unresolved. That is, the breakpoint does not match a symbolic reference in any currently loaded module. For information about these breakpoints, see [Unresolved Breakpoints \(bu Breakpoints\)](#).
- The virtual address or symbolic expression that makes up the breakpoint location. If you enabled source line number loading, the **bl** command displays file and line number information instead of address offsets. If the breakpoint is unresolved, the address is omitted here and appears at the end of the listing instead.

- (Data breakpoints only) Type and size information are displayed for data breakpoints. The types can be **e** (execute), **r** (read/write), **w** (write), or **i** (input/output). These types are followed with the size of the block, in bytes. For information about these breakpoints, see [Processor Breakpoints \(ba Breakpoints\)](#).
- The number of passes that remain until the breakpoint is activated, followed by the initial number of passes in parentheses. For more information about this kind of breakpoint, see the description of the *Passes* parameter in **bp, bu, bm (Set Breakpoint)**.
- The associated process and thread. If thread is given as three asterisks ("****"), this breakpoint is not a thread-specific breakpoint.
- The module and function, with offset, that correspond to the breakpoint address. If the breakpoint is unresolved, the breakpoint address appears here instead, in parentheses. If the breakpoint is set on a valid address but symbol information is missing, this field is blank.
- The command that is automatically executed when this breakpoint is hit. This command is displayed in quotation marks.

If you are not sure what command was used to set an existing breakpoint, use [.bpcmds \(Display Breakpoint Commands\)](#) to list all breakpoints along with the commands that were used to create them.

The following example shows the output of a **bl** command.

Example

```
0:000> bl
0 e 010049e0      0001 (0001)  0:**** stst!main
```

This output contains the following information:

- The breakpoint ID is **0**.
- The breakpoint status is **e** (enabled).
- The breakpoint is not unresolved (there is no **u** in the output).
- The virtual address of the breakpoint is **010049e0**.
- The breakpoint is active on the first pass through the code and the code has not yet been executed under the debugger. This information is indicated by a value of 1 (**0001**) in the "passes remaining" counter and a value of 1 (**(0001)**) in the initial passes counter.
- This breakpoint is not a thread-specific breakpoint (********).
- The breakpoint is set on **main** in the **stst** module.

[Send comments about this topic to Microsoft](#)

bp, bu, bm (Set Breakpoint)

5/31/2017 • 10 min to read • [Edit Online](#)

The **bp**, **bu**, and **bm** commands set one or more software breakpoints. You can combine locations, conditions, and options to set different kinds of software breakpoints.

User-Mode

```
[~Thread] bp[ID] [Options] [Address [Passes]] ["CommandString"]
[~Thread] bu[ID] [Options] [Address [Passes]] ["CommandString"]
[~Thread] bm [Options] SymbolPattern [Passes] ["CommandString"]
```

Kernel-Mode

```
bp[ID] [Options] [Address [Passes]] ["CommandString"]
bu[ID] [Options] [Address [Passes]] ["CommandString"]
bm [Options] SymbolPattern [Passes] ["CommandString"]
```

Parameters

Thread

Specifies the thread that the breakpoint applies to. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode. If you do not specify a thread, the breakpoint applies to all threads.

ID

Specifies a decimal number that identifies a breakpoint.

The debugger assigns the *ID* when it creates the breakpoint, but you can change it by using the **br (Breakpoint Rerumber)** command. You can use the *ID* to refer to the breakpoint in later debugger commands. To display the *ID* of a breakpoint, use the **bl (Breakpoint List)** command.

When you use *ID* in a command, do not type a space between the command (**bp** or **bu**) and the ID number.

The *ID* parameter is always optional. If you do not specify *ID*, the debugger uses the first available breakpoint number. In kernel mode, you can set only 32 breakpoints. In user mode, you can set any number of breakpoints. In either case, there is no restriction on the value of the *ID* number. If you enclose *ID* in square brackets (**[]**), *ID* can include any expression. For more information about the syntax, see [Numerical Expression Syntax](#).

Options

Specifies breakpoint options. You can specify any number of the following options, except as indicated:

/1

Creates a "one-shot" breakpoint. After this breakpoint is triggered, it is deleted from the breakpoint list.

/f PredNum

(Itanium-based only, user mode only) Specifies a predicate number. The breakpoint is predicated with the corresponding predicate register. (For example, **bp /f 4 address** sets a breakpoint that is predicated with the **p4** predicate register.)

/p EProcess

(Kernel-mode only) Specifies a process that is associated with this breakpoint. *EProcess* should be the actual address of the EPROCESS structure, not the PID. The breakpoint is triggered only if it is encountered in the context of this process.

/t *EThread*

(Kernel-mode only) Specifies a thread that is associated with this breakpoint. *EThread* should be the actual address of the ETHREAD structure, not the thread ID. The breakpoint is triggered only if it is encountered in the context of this thread. If you use **/p** *EProcess* and **/t** *EThread*, you can enter them in any order.

/c *MaxCallStackDepth*

Activates the breakpoint only when the call stack depth is less than *MaxCallStackDepth*. You cannot use this option together with **/C**.

/C *MinCallStackDepth*

Activates the breakpoint only when the call stack depth is larger than *MinCallStackDepth*. You cannot use this option together with **/c**.

/a

(For **bm** only) Sets breakpoints on all of the specified locations, whether they are in data space or code space. Because breakpoints on data can cause program failures, use this option only on locations that are known to be safe.

/d

(For **bm** only) Converts the breakpoint locations to addresses. Therefore, if the code is moved, the breakpoints remain at the same address, instead of being set according to *SymbolPattern*. Use **/d** to avoid reevaluating changes to breakpoints when modules are loaded or unloaded.

/

(For **bm** only) Includes parameter list information in the symbol string that *SymbolString* defines.

This feature enables you to set breakpoints on overloaded functions that have the same name but different parameter lists. For example, **bm /** *myFunc* sets breakpoints on both **myFunc(int a)** and **myFunc(char a)**. Without **"/"**, a breakpoint that is set on **myFunc** fails because it does not indicate which **myFunc** function the breakpoint is intended for.

Address

Specifies the first byte of the instruction where the breakpoint is set. If you omit *Address*, the current instruction pointer is used. For more information about the syntax, see [Address and Address Range Syntax](#).

Passes

Specifies the number of the execution pass that the breakpoint is activated on. The debugger skips the breakpoint location until it reaches the specified pass. The value of *Passes* can be any 16-bit or 32-bit value.

By default, the breakpoint is active the first time that the application executes the code that contains the breakpoint location. This default situation is equivalent to a value of **1** for *Passes*. To activate the breakpoint only after the application executes the code at least one time, enter a value of **2** or more. For example, a value of **2** activates the breakpoint the second time that the code is executed.

This parameter creates a counter that is decremented on each pass through the code. To see the initial and current values of the *Passes* counter, use [bl \(Breakpoint List\)](#).

The *Passes* counter is decremented only when the application executes past the breakpoint in response to a **g** (**Go**) command. The counter is not decremented if you are stepping through the code or tracing past it. When the *Passes* counter reaches **1**, you can reset it only by clearing and resetting the breakpoint.

CommandString

Specifies a list of commands that are executed every time that the breakpoint is encountered the specified number of times. You must enclose the *CommandString* parameter in quotation marks. Use semicolons to

separate multiple commands.

Debugger commands in *CommandString* can include parameters. You can use standard C-control characters (such as `\n` and `\\"`). Semicolons that are contained in second-level quotation marks (`\\"`) are interpreted as part of the embedded quoted string.

The *CommandString* commands are executed only if the breakpoint is reached while the application is *executing* in response to a [g \(Go\)](#) command. The commands are not executed if you are stepping through the code or tracing past this point.

Any command that resumes program execution after a breakpoint (such as `g` or `t`) ends the execution of the command list.

SymbolPattern

Specifies a pattern. The debugger tries to match this pattern to existing symbols and to set breakpoints on all pattern matches. *SymbolPattern* can contain a variety of wildcard characters and specifiers. For more information about this syntax, see [String Wildcard Syntax](#). Because these characters are being matched to symbols, the match is not case sensitive, and a single leading underscore (`_`) represents any quantity of leading underscores.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about and examples of how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

The **bp**, **bu**, and **bm** commands set new breakpoints, but they have different characteristics:

- The **bp (Set Breakpoint)** command sets a new breakpoint at the *address* of the breakpoint location that is specified in the command. If the debugger cannot resolve the address expression of the breakpoint location when the breakpoint is set, the **bp** breakpoint is automatically converted to a **bu** breakpoint. Use a **bp** command to create a breakpoint that is no longer active if the module is unloaded.
- The **bu (Set Unresolved Breakpoint)** command sets a *deferred* or *unresolved* breakpoint. A **bu** breakpoint is set on a symbolic reference to the breakpoint location that is specified in the command (not on an address) and is activated whenever the module with the reference is resolved. For more information about these breakpoints, see [Unresolved Breakpoints \(bu Breakpoints\)](#).
- The **bm (Set Symbol Breakpoint)** command sets a new breakpoint on symbols that match a specified pattern. This command can create more than one breakpoint. By default, after the pattern is matched, **bm** breakpoints are the same as **bu** breakpoints. That is, **bm** breakpoints are deferred breakpoints that are set on a symbolic reference. However, a **bm /d** command creates one or more **bp** breakpoints. Each breakpoint is set on the address of a matched location and does not track module

state.

If you are not sure what command was used to set an existing breakpoint, use [.bpcmds \(Display Breakpoint Commands\)](#) to list all breakpoints along with the commands that were used to create them.

There are three primary differences between **bp** breakpoints and **bu** breakpoints:

- A **bp** breakpoint location is always converted to an address. If a module change moves the code at which a **bp** breakpoint was set, the breakpoint remains at the same address. On the other hand, a **bu** breakpoint remains associated with the symbolic value (typically a symbol plus an offset) that was used, and it tracks this symbolic location even if its address changes.
- If a **bp** breakpoint address is found in a loaded module, and if that module is later unloaded, the breakpoint is removed from the breakpoint list. On the other hand, **bu** breakpoints persist after repeated unloads and loads.
- Breakpoints that you set with **bp** are not saved in WinDbg [workspaces](#). Breakpoints that are set with **bu** are saved in workspaces.

The **bm** command is useful when you want to use wildcard characters in the symbol pattern for a breakpoint. The **bm SymbolPattern** syntax is equivalent to using [x SymbolPattern](#) and then using **bu** on each result. For example, to set breakpoints on all of the symbols in the *Myprogram* module that begin with the string "mem," use the following command.

Example

```
0:000> bm myprogram!mem*
4: 0040d070 MyProgram!memcpy
5: 0040c560 MyProgram!memmove
6: 00408960 MyProgram!memset
```

Because the **bm** command sets software breakpoints (not processor breakpoints), it automatically excludes data location when it sets breakpoints to avoid corrupting the data.

It is possible to specify a data address rather than a program address when using the **bp** or **bm /a** commands. However, even if a data location is specified, these commands create software breakpoints, not processor breakpoints. If a software breakpoint is placed in program data instead of executable code, it can lead to data corruption. Therefore you should use these commands in a data location only if you are certain that the memory stored in that location will be used as executable code and not as program data. Otherwise, you should use the [ba \(Break on Access\)](#) command instead. For more details, see [Processor Breakpoints \(ba Breakpoints\)](#).

For details on how to set a breakpoint on a location specified by a more complicated syntax, such as a member of a C++ public class, or an arbitrary text string containing otherwise restricted characters, see [Breakpoint Syntax](#).

If a single logical source line spans multiple physical lines, the breakpoint is set on the last physical line of the statement or call. If the debugger cannot set a breakpoint at the requested position, it puts the breakpoint in the next allowed position.

If you specify *Thread*, breakpoints are set on the specified threads. For example, the **~*bp** command sets breakpoints on all threads, **~#bp** sets a breakpoint on the thread that causes the current exception, and **~123bp** sets a breakpoint on thread 123. The **~bp** and **~.bp** commands both set a breakpoint on the current thread.

When you are debugging a multiprocessor system in kernel mode, breakpoints that you set by using **bp** or [ba \(Break on Access\)](#) apply to all processors. For example, if the current processor is 3 and you type **bp**

MemoryAddress to put a breakpoint at **MemoryAddress**. Any processor that is executing at that address (not only processor 3) causes a breakpoint trap.

The **bp**, **bu**, and **bm** commands set software breakpoints by replacing the processor instruction with a break instruction. To debug read-only code or code that cannot be changed, use a **ba e** command, where **e** represents execute-only access.

The following command sets a breakpoint 12 bytes past the beginning of the function **MyTest**. This breakpoint is ignored for the first six passes through the code, but execution stops on the seventh pass through the code.

```
0:000> bp MyTest+0xb 7
```

The following command sets a breakpoint at **RtlRaiseException**, displays the **eax** register, displays the value of the symbol **MyVar**, and continues.

```
kd> bp ntdll!RtlRaiseException "r eax; dt MyVar; g"
```

The following two **bm** commands set three breakpoints. When the commands are executed, the displayed result does not distinguish between breakpoints created with the **/d** switch and those created without it. The **.bpcmds (Display Breakpoint Commands)** can be used to distinguish between these two types. If the breakpoint was created by **bm** without the **/d** switch, the **.bpcmds** display indicates the breakpoint type as **bu**, followed by the evaluated symbol enclosed in the **@!"** token (which indicates it is a literal symbol and not a numeric expression or register). If the breakpoint was created by **bm** with the **/d** switch, the **.bpcmds** display indicates the breakpoint type as **bp**.

```
0:000> bm myprog!openf*
0: 00421200 @!"myprog!openFile"
1: 00427800 @!"myprog!openFilter"

0:000> bm /d myprog!closef*
2: 00421600 @!"myprog!closeFile"

0:000> .bpcmds
bu0 @!"myprog!openFile";
bu1 @!"myprog!openFilter";
bp2 0x00421600 ;
```

[Send comments about this topic to Microsoft](#)

br (Breakpoint Renumber)

5/31/2017 • 1 min to read • [Edit Online](#)

The **br** command renames one or more breakpoints.

```
br OldID NewID [OldID2 NewID2 ...]
```

Parameters

OldID

Specifies the current ID number of the breakpoint.

NewID

Specifies a new number that becomes the ID of the breakpoint.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about and examples of how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#).

For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

You can use the **br** command to rename any number of breakpoints at the same time. For each breakpoint, list the old ID and the new ID, in that order, as parameters to **br**.

If there is already a breakpoint with an ID equal to *NewID*, the command fails and an error message is displayed.

[Send comments about this topic to Microsoft](#)

bs (Update Breakpoint Command)

5/31/2017 • 1 min to read • [Edit Online](#)

The **bs** command changes the command executed when the specified breakpoint is encountered.

```
bs ID ["CommandString"]
```

Parameters

ID

Specifies the ID number of the breakpoint.

CommandString

Specifies the new list of commands to be executed every time that the breakpoint is encountered. You must enclose the *CommandString* parameter in quotation marks. Use semicolons to separate multiple commands.

Debugger commands in *CommandString* can include parameters. You can use standard C-control characters (such as `\n` and `\\"`). Semicolons that are contained in second-level quotation marks (`\\"`) are interpreted as part of the embedded quoted string.

The *CommandString* commands are executed only if the breakpoint is reached while the application is executing in response to a **g (Go)** command. The commands are not executed if you are stepping through the code or tracing past this point.

Any command that resumes program execution after a breakpoint (such as **g** or **t**) ends the execution of the command list.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about and examples of how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#).

For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

If the *CommandString* is not specified, any commands already set on the breakpoint are removed.

[Send comments about this topic to Microsoft](#)

bsc (Update Conditional Breakpoint)

5/31/2017 • 1 min to read • [Edit Online](#)

The **bsc** command changes the condition under which a breakpoint occurs or changes the command executed when the specified conditional breakpoint is encountered.

```
bsc ID Condition ["CommandString"]
```

Parameters

ID

Specifies the ID number of the breakpoint.

Condition

Specifies the condition under which the breakpoint should be triggered.

CommandString

Specifies the new list of commands to be executed every time that the breakpoint is encountered. You must enclose the *CommandString* parameter in quotation marks. Use semicolons to separate multiple commands.

Debugger commands in *CommandString* can include parameters. You can use standard C-control characters (such as `\n` and `\\"`). Semicolons that are contained in second-level quotation marks (`\\"`) are interpreted as part of the embedded quoted string.

The *CommandString* commands are executed only if the breakpoint is reached while the application is executing in response to a **g (Go)** command. The commands are not executed if you are stepping through the code or tracing past this point.

Any command that resumes program execution after a breakpoint (such as **g** or **t**) ends the execution of the command list.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about and examples of how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, and how to set breakpoints in user space from a kernel debugger, see [Using Breakpoints](#). For more information about conditional breakpoints, see [Setting a Conditional Breakpoint](#).

Remarks

If the *CommandString* is not specified, any commands already set on the breakpoint are removed.

The same effect can be achieved by using the **bs (Update Breakpoint Command)** command with the following

syntax:

```
bs ID "j Condition 'CommandString'; 'gc'"
```

[Send comments about this topic to Microsoft](#)

c (Compare Memory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **c** command compares the values held in two memory areas.

```
c Range Address
```

Parameters

Range

The first of the two memory ranges to be compared. For more syntax details, see [Address and Address Range Syntax](#).

Address

The starting address of the second memory range to be compared. The size of this range will be the same as that specified for the first range. For more syntax details, see [Address and Address Range Syntax](#).

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

If the two areas are not identical, the debugger will display all memory addresses in the first range where they do not agree.

As an example, consider the following code:

```
void main()
{
    char rgBuf1[100];
    char rgBuf2[100];

    memset(rgBuf1, 0xCC, sizeof(rgBuf1));
    memset(rgBuf2, 0xCC, sizeof(rgBuf2));

    rgBuf1[42] = 0xFF;
}
```

To compare **rgBuf1** and **rgBuf2**, use either of the following commands:

```
0:000> c rgBuf1 (rgBuf1+0n100) rgBuf2
```

```
0:000> c rgBuf1 L 0n100 rgBuf2
```

[Send comments about this topic to Microsoft](#)

d, da, db, dc, dd, dD, df, dp, dq, du, dw (Display Memory)

5/31/2017 • 4 min to read • [Edit Online](#)

The **d*** commands display the contents of memory in the given range.

```
d{a|b|c|d|D|f|p|q|u|w|W} [Options] [Range]
dy{b|d} [Options] [Range]
d [Options] [Range]
```

Parameters

Options

Specifies one or more display options. Any of the following options can be included, except that no more than one **/p*** option can be indicated:

/cWidth

Specifies the number of columns to use in the display. If this is omitted, the default number of columns depends on the display type.

/p

(Kernel-mode only) Uses physical memory addresses for the display. The range specified by *Range* will be taken from physical memory rather than virtual memory.

/p[c]

(Kernel-mode only) Same as **/p**, except that cached memory will be read. The brackets around **c** must be included.

/p[uc]

(Kernel-mode only) Same as **/p**, except that uncached memory will be read. The brackets around **uc** must be included.

/p[wc]

(Kernel-mode only) Same as **/p**, except that write-combined memory will be read. The brackets around **wc** must be included.

Range

Specifies the memory area to display. For more syntax details, see [Address and Address Range Syntax](#). If you omit *Range*, the command will display memory starting at the ending location of the last display command. If *Range* is omitted and no previous display command has been used, the display begins at the current instruction pointer.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump

Platforms	all										
Additional Information											
For an overview of memory manipulation and a description of other memory-related commands, see Reading and Writing Memory .											
Remarks											
Each line displayed will include the address of the first byte in the line followed by the contents of memory at that and following locations.											
If you omit <i>Range</i> , the command will display memory starting at the ending location of the last display command. This allows you to continuously scan through memory.											
This command exists in the following forms. The second characters of the dd , dD , dw , and dW commands are case-sensitive, as are the third characters of the dyb and dyd commands.											
<table border="1"> <thead> <tr> <th>COMMAND</th><th>DISPLAY</th></tr> </thead> <tbody> <tr> <td>d</td><td> <p>This displays data in the same format as the most recent d command. If no previous d command has been issued, d has the same effect as db.</p> <p>Notice that d repeats the most recent command that began with d. This includes dda, ddp, ddu, dpa, dpp, dpu, dqa, dqp, dqu, dds, dps, dqs, ds, dS, dg, dl, dt, and dv, as well as the display commands on this page. If the parameters given after d are not appropriate, errors may result.</p> </td></tr> <tr> <td>da</td><td> <p>ASCII characters.</p> <p>Each line displays up to 48 characters. The display continues until the first null byte or until all characters in <i>range</i> have been displayed. All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.)</p> </td></tr> <tr> <td>db</td><td> <p>Byte values and ASCII characters.</p> <p>Each display line shows the address of the first byte in the line, followed by up to 16 hexadecimal byte values. The byte values are immediately followed by the corresponding ASCII values. The eighth and ninth hexadecimal values are separated by a hyphen (-). All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.)</p> <p>The default count is 128 bytes.</p> </td></tr> <tr> <td>dc</td><td> <p>Double-word values (4 bytes) and ASCII characters.</p> <p>Each display line shows the address of the first word in the line and up to eight hexadecimal word values, as well as their ASCII equivalent.</p> <p>The default count is 32 DWORDs (128 bytes).</p> </td></tr> </tbody> </table>		COMMAND	DISPLAY	d	<p>This displays data in the same format as the most recent d command. If no previous d command has been issued, d has the same effect as db.</p> <p>Notice that d repeats the most recent command that began with d. This includes dda, ddp, ddu, dpa, dpp, dpu, dqa, dqp, dqu, dds, dps, dqs, ds, dS, dg, dl, dt, and dv, as well as the display commands on this page. If the parameters given after d are not appropriate, errors may result.</p>	da	<p>ASCII characters.</p> <p>Each line displays up to 48 characters. The display continues until the first null byte or until all characters in <i>range</i> have been displayed. All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.)</p>	db	<p>Byte values and ASCII characters.</p> <p>Each display line shows the address of the first byte in the line, followed by up to 16 hexadecimal byte values. The byte values are immediately followed by the corresponding ASCII values. The eighth and ninth hexadecimal values are separated by a hyphen (-). All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.)</p> <p>The default count is 128 bytes.</p>	dc	<p>Double-word values (4 bytes) and ASCII characters.</p> <p>Each display line shows the address of the first word in the line and up to eight hexadecimal word values, as well as their ASCII equivalent.</p> <p>The default count is 32 DWORDs (128 bytes).</p>
COMMAND	DISPLAY										
d	<p>This displays data in the same format as the most recent d command. If no previous d command has been issued, d has the same effect as db.</p> <p>Notice that d repeats the most recent command that began with d. This includes dda, ddp, ddu, dpa, dpp, dpu, dqa, dqp, dqu, dds, dps, dqs, ds, dS, dg, dl, dt, and dv, as well as the display commands on this page. If the parameters given after d are not appropriate, errors may result.</p>										
da	<p>ASCII characters.</p> <p>Each line displays up to 48 characters. The display continues until the first null byte or until all characters in <i>range</i> have been displayed. All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.)</p>										
db	<p>Byte values and ASCII characters.</p> <p>Each display line shows the address of the first byte in the line, followed by up to 16 hexadecimal byte values. The byte values are immediately followed by the corresponding ASCII values. The eighth and ninth hexadecimal values are separated by a hyphen (-). All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.)</p> <p>The default count is 128 bytes.</p>										
dc	<p>Double-word values (4 bytes) and ASCII characters.</p> <p>Each display line shows the address of the first word in the line and up to eight hexadecimal word values, as well as their ASCII equivalent.</p> <p>The default count is 32 DWORDs (128 bytes).</p>										

COMMAND	DISPLAY
dd	Double-word values (4 bytes). The default count is 32 DWORDs (128 bytes).
dD	Double-precision floating-point numbers (8 bytes). The default count is 15 numbers (120 bytes).
df	Single-precision floating-point numbers (4 bytes). The default count is 16 numbers (64 bytes).
dp	Pointer-sized values. This command is equivalent to dd or dq , depending on whether the target computer's processor architecture is 32-bit or 64-bit, respectively. The default count is 32 DWORDs or 16 quad-words (128 bytes).
dq	Quad-word values (8 bytes). The default count is 16 quad-words (128 bytes).
du	Unicode characters. Each line displays up to 48 characters. The display continues until the first null byte or until all characters in <i>range</i> have been displayed. All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.).
dw	Word values (2 bytes). Each display line shows the address of the first word in the line and up to eight hexadecimal word values. The default count is 64 words (128 bytes).
dW	Word values (2 bytes) and ASCII characters. Each display line shows the address of the first word in the line and up to eight hexadecimal word values. The default count is 64 words (128 bytes).
dyb	Binary values and byte values. The default count is 32 bytes.
dyd	Binary values and double-word values (4 bytes). The default count is 8 DWORDs (32 bytes).

If you attempt to display an invalid address, its contents are shown as question marks (?).

dda, ddp, ddu, dpa, dpp, dpu, dqa, dqp, dqu (Display Referenced Memory)

5/31/2017 • 2 min to read • [Edit Online](#)

The **dda**, **ddp**, **ddu**, **dpa**, **dpp**, **dpu**, **dqa**, **dqp**, and **dqu** commands display the pointer at the specified location, dereference that pointer, and then display the memory at the resulting location in a variety of formats.

```
ddp [Options] [Range]
dqp [Options] [Range]
dpp [Options] [Range]
dda [Options] [Range]
dqa [Options] [Range]
dpa [Options] [Range]
ddu [Options] [Range]
dqu [Options] [Range]
dpu [Options] [Range]
```

Parameters

Options

Specifies one or more display options. Any of the following options can be included, except that no more than one **/p*** option can be indicated:

/cWidth

Specifies the number of columns to use in the display. If this is omitted, the default number of columns depends on the display type. Because of the way pointers are displayed by these commands, it is usually best to use the default of only one data column.

/p

(Kernel-mode only) Uses physical memory addresses for the display. The range specified by *Range* will be taken from physical memory rather than virtual memory.

/p[c]

(Kernel-mode only) Same as **/p**, except that cached memory will be read. The brackets around **c** must be included.

/p[uc]

(Kernel-mode only) Same as **/p**, except that uncached memory will be read. The brackets around **uc** must be included.

/p[wc]

(Kernel-mode only) Same as **/p**, except that write-combined memory will be read. The brackets around **wc** must be included.

Range

Specifies the memory area to display. For more syntax details, see [Address and Address Range Syntax](#). If you omit *Range*, the command will display memory starting at the ending location of the last display command. If *Range* is omitted and no previous display command has been used, the display begins at the current instruction pointer. If a simple address is given, the default range length is 128 bytes.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

The second and third characters of this command are case-sensitive.

The second character of this command determines the pointer size used:

COMMAND	DISPLAY
dd	32-bit pointers used
dq	64-bit pointers used
dp*	Standard pointer sizes used: 32-bit or 64-bit, depending on the target's processor architecture

The third character of this command determines how the dereferenced memory is displayed:

COMMAND	DISPLAY
dp	Displays the contents of the memory referenced by the pointer in DWORD or QWORD format, depending on the pointer size of the target's processor architecture. If this value matches any known symbol, this symbol is displayed as well.
da	Displays the contents of the memory referenced by the pointer in ASCII character format.
d*u	Displays the contents of the memory referenced by the pointer in Unicode character format.

If line number information has been enabled, source file names and line numbers will be displayed when available.

[Send comments about this topic to Microsoft](#)

dds, dps, dqs (Display Words and Symbols)

5/31/2017 • 2 min to read • [Edit Online](#)

The **dds**, **dps**, and **dqs** commands display the contents of memory in the given range. This memory is assumed to be a series of addresses in the symbol table. The corresponding symbols are displayed as well.

```
dds [Options] [Range]
dqs [Options] [Range]
dps [Options] [Range]
```

Parameters

Options

Specifies one or more display options. Any of the following options can be included, except that no more than one **/p*** option can be indicated:

/c *Width*

Specifies the number of columns to use in the display. If this is omitted, the default number of columns depends on the display type. Because of the way symbols are displayed by these commands, it is usually best to use the default of only one data column.

/p

(Kernel-mode only) Uses physical memory addresses for the display. The range specified by *Range* will be taken from physical memory rather than virtual memory.

/p[c]

(Kernel-mode only) Same as **/p**, except that cached memory will be read. The brackets around **c** must be included.

/p[uc]

(Kernel-mode only) Same as **/p**, except that uncached memory will be read. The brackets around **uc** must be included.

/p[wc]

(Kernel-mode only) Same as **/p**, except that write-combined memory will be read. The brackets around **wc** must be included.

Range

Specifies the memory area to display. For more syntax details, see [Address and Address Range Syntax](#). If you omit *Range*, the command will display memory starting at the ending location of the last display command. If *Range* is omitted and no previous display command has been used, the display begins at the current instruction pointer. If a simple address is given, the default range length is 128 bytes.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

The second character of **dds** is case-sensitive. The third character of all these commands is case-sensitive.

The **dds** command displays double-word (4 byte) values like the **dd** command. The **dqs** command displays quad-word (8 byte) values like the **dq** command. The **dps** command displays pointer-sized values (4 byte or 8 byte, depending on the target computer's architecture) like the **dp** command.

Each of these words is treated as an address in the symbol table. The corresponding symbol information is displayed for each word.

If line number information has been enabled, source file names and line numbers will be displayed when available.

[Send comments about this topic to Microsoft](#)

dg (Display Selector)

5/31/2017 • 1 min to read • [Edit Online](#)

The **dg** command shows the segment descriptor for the specified selector.

```
dg FirstSelector [LastSelector]
```

Parameters

FirstSelector

Specifies the hexadecimal selector value of the first selector to be displayed.

LastSelector

Specifies the hexadecimal selector value of the last selector to be displayed. If this is omitted, only one selector will be displayed.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	x86, Itanium

Remarks

No more than 256 selectors can be displayed by this command.

Common selector values are:

ID	DECIMAL	HEX
KGDT_NULL	0	0x00
KGDT_R0_CODE	8	0x08
KGDT_R0_DATA	16	0x10
KGDT_R3_CODE	24	0x18
KGDT_R3_DATA	32	0x20
KGDT_TSS	40	0x28

ID	DECIMAL	HEX
KGDT_R0_PCR	48	0x30
KGDT_R3_TEB	56	0x38
KGDT_VDM_TILE	64	0x40
KGDT_LDT	72	0x48
KGDT_DF_TSS	80	0x50
KGDT_NMI_TSS	88	0x58

[Send comments about this topic to Microsoft](#)

dl (Display Linked List)

5/31/2017 • 1 min to read • [Edit Online](#)

The **dl** command displays a LIST_ENTRY or SINGLE_LIST_ENTRY linked list.

```
dl[b] Address MaxCount Size
```

Parameters

b

If this is included, the list is dumped in reverse order. (In other words, the debugger follows the **Blinks** instead of the **Flinks**.) This cannot be used with a SINGLE_LIST_ENTRY.

Address

The starting address of the list. For more syntax details, see [Address and Address Range Syntax](#).

MaxCount

Maximum number of elements to dump.

Size

Size of each element. This is the number of consecutive ULONG_PTRs that will be displayed for each element in the list.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

This list must be a LIST_ENTRY or SINGLE_LIST_ENTRY structure. If this is embedded in a larger structure, be sure that *Address* points to the linked list structure and not to the beginning of the outer structure.

The display begins with *Address*. Therefore, if you are supplying the address of a pointer that points to the beginning of the list, you should disregard the first element printed.

The *Address*, *MaxCount*, and *Size* parameters are in the current default radix. You can use the [n \(Set Number Base\)](#) command or the **0x** prefix to change the radix.

If the list loops back on itself, the dump will stop. If a null pointer is encountered, the dump will stop.

If you want to execute some command for each element of the list, use the **!list** extension.

[Send comments about this topic to Microsoft](#)

ds, dS (Display String)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ds** and **dS** commands display a STRING, ANSI_STRING, or UNICODE_STRING structure. (These commands do not display null-delimited character strings.)

```
d{s|S} [/c Width] [Address]
```

Parameters

s

Specifies that a STRING or ANSI_STRING structure is to be displayed. (This **s** is case-sensitive.)

S

Specifies that a UNICODE_STRING structure is to be displayed. (This **S** is case-sensitive.)

/c Width

Specifies the number of characters to display on each line. This number includes null characters, which will not be visible.

Address

The memory address where the string begins. For more syntax details, see [Address and Address Range Syntax](#). If omitted, the last address used in a display command is assumed.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

If you want to display Unicode strings in the Locals window or Watch window of WinDbg, you need to use the [.enable_unicode \(Enable Unicode Display\)](#) command first.

[Send comments about this topic to Microsoft](#)

dt (Display Type)

5/31/2017 • 11 min to read • [Edit Online](#)

The **dt** command displays information about a local variable, global variable or data type. This can display information about simple data types, as well as structures and unions.

User-Mode Syntax

```
dt [-DisplayOpts] [-SearchOpts] [module!]Name [[-SearchOpts] Field] [Address] [-l List]
dt [-DisplayOpts] Address [-l List]
dt -h
```

Kernel-Mode Syntax

```
[Processor] dt [-DisplayOpts] [-SearchOpts] [module!]Name [[-SearchOpts] Field] [Address] [-l List]
dt [-DisplayOpts] Address [-l List]
dt -h
```

Parameters

Processor

Specifies the processor that is running the process containing the information needed. For more information, see [Multiprocessor Syntax](#). Processors can only be specified in kernel mode.

DisplayOpts

Specifies one or more of the options given in the following table. These options are preceded by a hyphen.

OPTION	DESCRIPTION
-a[<i>quantity</i>]	Show each array element on a new line, with its index. A total of <i>quantity</i> elements will be displayed. There must be no space between the -a and the <i>quantity</i> . If -a is not followed by a digit, all items in the array are shown. The -a[<i>quantity</i>] switch should appear immediately before each type name or field name that you want displayed in this manner.
-b	Display blocks recursively. If a displayed structure contains substructures, it is expanded recursively to arbitrary depths and displayed in full. Pointers are expanded only if they are in the original structure, not in substructures.
-c	Compact output. All fields are displayed on one line, if possible. (When used with the -a switch, each array element takes one line rather than being formatted as a several-line block.)

OPTION	DESCRIPTION
-d	When used with a <i>Name</i> that is ended with an asterisk, display verbose output for all types that begin with <i>Name</i> . If <i>Name</i> does not end with an asterisk, display verbose output.
-e	Forces dt to enumerate types. This option is only needed if dt is mistakenly interpreting the <i>Name</i> value as an instance rather than as a type.
-i	Do not indent the subtypes.
-o	Omit offset values of the structure fields.
-p	<i>Address</i> is a physical address, rather than a virtual address.
-r[<i>depth</i>]	Recursively dumps the subtype fields. If <i>depth</i> is given, this recursion will stop after <i>depth</i> levels. The <i>depth</i> must be a digit between 1 and 9, and there must be no space between the r and the <i>depth</i> . The -r[<i>depth</i>] switch should appear immediately before the address.
-s <i>size</i>	Enumerate only those types whose size in bytes equals the value of <i>size</i> . The -s option is only useful when types are being enumerated. When -s is specified, -e is always implied as well.
-t	Enumerate types only.
-v	Verbose output. This gives additional information such as the total size of a structure and the number of its elements. When this is used along with the -y search option, all symbols are displayed, even those with no associated type information.

SearchOpts

Specifies one or more of the options given in the following table. These options are preceded by a hyphen.

OPTION	DESCRIPTION
-n	This indicates that the next parameter is a name. This should be used if the next item consists entirely of hexadecimal characters, because it will otherwise be taken as an address.

OPTION	DESCRIPTION
-y	This indicates that the next parameter is the beginning of the name, not necessarily the entire name. When -y is included, all matches are listed, followed by detailed information on the first match in the list. If -y is not included, only exact matches will be displayed.

module

An optional parameter specifying the module that defines this structure. If there is a local variable or type with the same name as a global variable or type, you should include *module* to specify that you mean the global variable. Otherwise, the **dt** command will display the local variable, even if the local variable is a case-insensitive match and the global variable is a case-sensitive match.

Name

Specifies the name of a type or global variable. If *Name* ends with an asterisk (V), a list of all matches is displayed. Thus, ****dt A**** will list all data types, globals, and statics beginning with "A", but will not display the actual instances of these types. (If the **-v** display option is used at the same time, all symbols will be displayed -- not just those with associated type information.) You can also replace *Name* with a period (.) to signify that you want to repeat the most recently used value of *Name*.

If *Name* contains a space, it should be enclosed in parentheses.

Field

Specifies the field(s) to be displayed. If *Field* is omitted, all fields are displayed. If *Field* is followed by a period (.), the first-level subfields of this field will be displayed as well. If *Field* is followed with a series of periods, the subfields will be displayed to a depth equal to the number of periods. Any field name followed by a period will be treated as a prefix match, as if the **-y** search option was used. If *Field* is followed by an asterisk (*), it is treated as only the beginning of the field, not necessarily the entire field, and all matching fields are displayed.

Address

Specifies the address of the structure to be displayed. If *Name* is omitted, *Address* must be included and must specify the address of a global variable. *Address* is taken to be a virtual address unless otherwise specified. Use the **-p** option to specify a physical address. Use an "at" sign (@) to specify a register (for example, **@eax**).

List

Specifies the field name that links a linked list. The *Address* parameter must be included.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

The **dt** command output will always display signed numbers in base 10, and unsigned numbers in hexadecimal.

All parameters of **dt** that allow symbol values also allow string wildcards. See [String Wildcard Syntax](#) for details.

The **-y** and **-n** options can precede any *Name* or *Field*. The **-y** option allows you to specify the beginning of the type or structure name. For example, **dt -y ALLEN** will display data about the type **ALLENTOWN**.

However, you could not display the type **ALLENTOWN** with **dt -y A**. Instead, you would have to use **dt -ny A**, because **A** is a valid hexadecimal value and would be interpreted as an address without the **-n** option.

If *Name* indicates a structure, all fields will be displayed (for example, **dt myStruct**). If you only want one specific field, you can do **dt myStruct myField**. This displays the member that C would call **myStruct.myField**. However, note that the command **dt myStruct myField1 myField2** displays **myStruct.myField1** and **myStruct.myField2**. It does not display **myStruct.myField1.myField2**.

If a structure name or field is followed by a subscript, this specifies a single instance of an array. For example, **dt myStruct myFieldArray[3]** will display the fourth element of the array in question. But if a type name is followed by a subscript, this specifies an entire array. For example, **dt CHAR[8] myPtr** will display an eight-character string. The subscript is always taken as decimal regardless of the current radix; an **0x** prefix will cause an error.

Because the command uses type information from the *.pdb* file, it can freely be used to debug any CPU platform.

The type information used by **dt** includes all type names created with **typedef**, including all the Windows-defined types. For example, **unsigned long** and **char** are not valid type names, but **ULONG** and **CHAR** are. See the Microsoft Windows SDK for a full list of all Windows type names.

All types created by **typedefs** within your own code will be present, as long as they have actually been used in your program. However, types that are defined in your headers but never actually used will not be stored in the *.pdb* symbol files and will not be accessible to the debugger. To make such a type available to the debugger, use it as the *input* of a **typedef** statement. For example, if the following appears in your code, the structure **MY_DATA** will be stored in the *.pdb* symbol file and can be displayed by the **dt** command:

```
typedef struct _MY_DATA {  
    . . .  
} MY_DATA;  
typedef MY_DATA *PMY_DATA;
```

On the other hand, the following code would not suffice because both **MY_DATA** and **PMY_DATA** are defined by the initial **typedef** and, therefore, **MY_DATA** has not itself been used as the input of any **typedef** statement:

```
typedef struct _MY_DATA {  
    . . .  
} MY_DATA, *PMY_DATA;
```

In any event, type information is included only in a full symbol file, not a symbol file that has been stripped of all private symbol information. For more information, see [Public and Private Symbols](#).

If you want to display unicode strings, you need to use the [.enable_unicode \(Enable Unicode Display\)](#) command first. You can control the display of long integers with the [.enable_long_status \(Enable Long](#)

Integer Display) command.

In the following example, **dt** displays a global variable:

```
0:000> dt mt1
+0x000 a : 10
+0x004 b : 98 'b'
+0x006 c : 0xdd
+0x008 d : 0xabcd
+0x00c gn : [6] 0x1
+0x024 ex : 0x0
```

In the following example, **dt** displays the array field **gn**:

```
0:000> dt mt1 -a gn
+0x00c gn :
[00] 0x1
[01] 0x2
[02] 0x3
[03] 0x4
[04] 0x5
[05] 0x6
```

The following command displays some subfields of a variable:

```
0:000> dt mcl1 m_t1 dpo
+0x010 dpo : DEEP_ONE
+0x070 m_t1 : MYTYPE1
```

The following command displays the subfields of the field **m_t1**. Because the period automatically causes prefix matching, this will also display subfields of any field that begins with "m_t1":

```
0:000> dt mcl1 m_t1.
+0x070 m_t1 :
+0x000 a : 0
+0x004 b : 0 '
+0x006 c : 0x0
+0x008 d : 0x0
+0x00c gn : [6] 0x0
+0x024 ex : 0x0
```

You could repeat this to any depth. For example, the command **dt mcl1 a..c** would display all fields to depth four, such that the first field name began with **a** and the third field name began with **c**.

Here is a more detailed example of how subfields can be displayed. First, display the **Ldr** field:

```
0:000> dt nt!_PEB Ldr 7ffdf000
+0x00c Ldr : 0x00191ea0
```

Now expand the pointer type field:

```
0:000> dt nt!_PEB Ldr Ldr. 7ffd000
+0x00c Ldr : 0x00191ea0
+0x000 Length : 0x28
+0x004 Initialized : 0x1 '
+0x008 SsHandle : (null)
+0x00c InLoadOrderModuleList : _LIST_ENTRY [ 0x191ee0 - 0x192848 ]
+0x014 InMemoryOrderModuleList : _LIST_ENTRY [ 0x191ee8 - 0x192850 ]
+0x01c InInitializationOrderModuleList : _LIST_ENTRY [ 0x191f58 - 0x192858 ]
+0x024 EntryInProgress : (null)
```

Now display the **CriticalSectionTimeout** field:

```
0:000> dt nt!_PEB CriticalSectionTimeout 7ffd000
+0x070 CriticalSectionTimeout : _LARGE_INTEGER 0xfffffe86d`079b8000
```

Now expand the **CriticalSectionTimeout** structure subfields one level deep:

```
0:000> dt nt!_PEB CriticalSectionTimeout. 7ffd000
+0x070 CriticalSectionTimeout : 0xfffffe86d`079b8000
+0x000 LowPart : 0x79b8000
+0x004 HighPart : -6035
+0x000 u : __unnamed
+0x000 QuadPart : -2592000000000000
```

Now expand the **CriticalSectionTimeout** structure subfields two levels deep:

```
0:000> dt nt!_PEB CriticalSectionTimeout.. 7ffd000
+0x070 CriticalSectionTimeout : 0xfffffe86d`079b8000
+0x000 LowPart : 0x79b8000
+0x004 HighPart : -6035
+0x000 u :
+0x000 LowPart : 0x79b8000
+0x004 HighPart : -6035
+0x000 QuadPart : -2592000000000000
```

The following command displays an instance of the data type MYTYPE1 that is located at the address 0x0100297C:

```
0:000> dt 0x0100297c MYTYPE1
+0x000 a : 22
+0x004 b : 43 '+'
+0x006 c : 0x0
+0x008 d : 0x0
+0x00c gn : [6] 0x0
+0x024 ex : 0x0
```

The following command displays an array of 10 ULONGs at the address 0x01002BE0:

```
0:000> dt -ca10 ULONG 01002be0
[0] 0x1001098
[1] 0x1
[2] 0xdead
[3] 0x7d0
[4] 0x1
[5] 0xcd
[6] 0x0
[7] 0x0
[8] 0x0
[9] 0x0
```

The following command continues the previous display at a different address. Note that "ULONG" does not need to be re-entered:

```
0:000> dt -ca4 . 01002d00
Using sym ULONG
[0] 0x12
[1] 0x4ac
[2] 0xbadfeed
[3] 0x2
```

Here are some examples of type display. The following command displays all types and globals beginning with the string "MY" in the module *thismodule*. Those prefixed with an address are actual instances; those without addresses are type definitions:

```
0:000> dt thismodule!MY*
010029b8  thismodule!myglobal1
01002990  thismodule!myglobal2
           thismodule!MYCLASS1
           thismodule!MYCLASS2
           thismodule!MYCLASS3
           thismodule!MYTYPE3::u
           thismodule!MYTYPE1
           thismodule!MYTYPE3
           thismodule!MYTYPE3
           thismodule!MYFLAGS
```

When performing type display, the **-v** option can be used to display the size of each item. The **-s size** option can be used to only enumerate items of a specific size. Again, those prefixed with an address are actual instances; those without addresses are type definitions:

```
0:001> dt -s 2 -v thismodule!*
Enumerating symbols matching thismodule!*, Size = 0x2
Address  Size Symbol
002      thismodule!wchar_t
002      thismodule!WORD
002      thismodule!USHORT
002      thismodule!SHORT
002      thismodule!u_short
002      thismodule!WCHAR
00427a34  002      thismodule!numberOfShips
00427a32  002      thismodule!numberOfPlanes
00427a30  002      thismodule!totalNumberOfItems
```

Here is an example of the **-b** option. The structure is expanded and the **OwnerThreads** array within the structure is expanded, but the **Flink** and **Blink** list pointers are not followed:

```

kd> dt nt!_ERESOURCE -b 0x8154f040
+0x000 SystemResourcesList : [ 0x815bb388 - 0x816cd478 ]
+0x000 Flink : 0x815bb388
+0x004 Blink : 0x816cd478
+0x008 OwnerTable : (null)
+0x00c ActiveCount : 1
+0x00e Flag : 8
+0x010 SharedWaiters : (null)
+0x014 ExclusiveWaiters : (null)
+0x018 OwnerThreads :
[00]
+0x000 OwnerThread : 0
+0x004 OwnerCount : 0
+0x004 TableSize : 0
[01]
+0x000 OwnerThread : 0x8167f563
+0x004 OwnerCount : 1
+0x004 TableSize : 1
+0x028 ContentionCount : 0
+0x02c NumberOfSharedWaiters : 0
+0x02e NumberOfExclusiveWaiters : 0
+0x030 Address : (null)
+0x030 CreatorBackTraceIndex : 0
+0x034 SpinLock : 0

```

Here is an example of **dt** in kernel mode. The following command produces results similar to [!process 0 0](#):

```

kd> dt nt!_EPROCESS -l ActiveProcessLinks.Flink -y Ima -yo! Uni 814856f0
## ActiveProcessLinks.Flink at 0x814856f0

UniqueProcessId : 0x00000008
ImageFileName : [16] "System"

## ActiveProcessLinks.Flink at 0x8138a030

UniqueProcessId : 0x00000084
ImageFileName : [16] "smss.exe"

## ActiveProcessLinks.Flink at 0x81372368

UniqueProcessId : 0x000000a0
ImageFileName : [16] "csrss.exe"

## ActiveProcessLinks.Flink at 0x81369930

UniqueProcessId : 0x000000b4
ImageFileName : [16] "winlogon.exe"

....

```

If you want to execute a command for each element of the list, use the [!list](#) extension.

Finally, the **dt -h** command will display a short help text summarizing the **dt** syntax.

[Send comments about this topic to Microsoft](#)

dtx (Display Type - Extended Debugger Object Model Information)

5/31/2017 • 1 min to read • [Edit Online](#)

The dtx command displays extended symbolic type information using the debugger object model. The dtx command is similar to the [dt \(Display Type\)](#) command.

```
dtx -DisplayOpts [Module!]Name Address
```

Parameters

DisplayOpts

Use the following optional flags to change how the output is displayed.

-a Displays array elements in a new line with its index.

-r [n] Recursively dump the subtypes (fields) up to *n* levels.

-h Displays command line help for the dtx command.

Module!

An optional parameter specifying the module that defines this structure, followed by the exclamation point. If there is a local variable or type with the same name as a global variable or type, you should include *module* name to specify the global variable.

Name

A type name or a global symbol.

Address

Memory address containing the type.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

The following examples show how to use the dtx command.

Use the address and the name to display extended symbolic type information.

```
0: kd> dtx nt!_EPROCESS fffffb607560b56c0
(*((nt!_EPROCESS *)0xfffffb607560b56c0)) [Type: _EPROCESS]
  [+0x000] Pcb [Type: _KPROCESS]
  [+0x2d8] ProcessLock [Type: _EX_PUSH_LOCK]
  [+0x2e0] RundownProtect [Type: _EX_RUNDOWN_REF]
  [+0x2e8] UniqueProcessId : 0x4 [Type: void *]
  [+0x2f0] ActiveProcessLinks [Type: _LIST_ENTRY]
```

Display additional information using the -r recursion option.

```
0: kd> dtx -r2 HdAudio!CAzMixertopoMiniport fffff806`d24992b8
(*((HdAudio!CAzMixertopoMiniport *)0xfffff806d24992b8)) [Type: CAzMixertopoMiniport]
  [+0x018] m_lRefCount : -766760880 [Type: long]
  [+0x020] m_pUnknownOuter : 0xfffff806d24dbc40 [Type: IUnknown *]
  [+0x028] m_FilterDesc [Type: PCFILTER_DESCRIPTOR]
    [+0x000] Version : 0xd24c2890 [Type: unsigned long]
    [+0x008] AutomationTable : 0xfffff806d24c2780 [Type: PCAUTOMATION_TABLE *]
      [+0x000] PropertyItemSize : 0x245c8948 [Type: unsigned long]
      [+0x004] PropertyCount : 0x6c894808 [Type: unsigned long]
      [+0x008] Properties : 0x5718247489481024 [Type: PCPROPERTY_ITEM *]
      [+0x010] MethodItemSize : 0x55415441 [Type: unsigned long]
      [+0x014] MethodCount : 0x57415641 [Type: unsigned long]
      [+0x018] Methods : 0x4ce4334540ec8348 [Type: PCMETHOD_ITEM *]
      [+0x020] EventItemSize : 0x8b41f18b [Type: unsigned long]
      [+0x024] EventCount : 0xd8b48f4 [Type: unsigned long]
      [+0x028] Events : 0x7d2d8d4cfffd854 [Type: PCEVENT_ITEM *]
      [+0x030] Reserved : 0x66ffd79 [Type: unsigned long]
    [+0x010] PinSize : 0xd24aa9b0 [Type: unsigned long]
    [+0x014] PinCount : 0xfffff806 [Type: unsigned long]
    [+0x018] Pins : 0xfffff806d24aa740 [Type: PCPIN_DESCRIPTOR *]
      [+0x000] MaxGlobalInstanceCount : 0x57555340 [Type: unsigned long]
      [+0x004] MaxFilterInstanceCount : 0x83485741 [Type: unsigned long]
      [+0x008] MinFilterInstanceCount : 0x8b4848ec [Type: unsigned long]
      [+0x010] AutomationTable : 0xa5158b48ed33c000 [Type: PCAUTOMATION_TABLE *]
      [+0x018] KsPinDescriptor [Type: KSPIN_DESCRIPTOR]
```

Tip: Use the [x \(Examine Symbols\)](#) command to display the address of an item of interest.

```
0: kd> x /d HdAudio!CazMixertopoMiniport*
...
fffff806`d24992b8 HdAudio!CAzMixertopoMiniport::`vftable' = <no type information>
...
```

[dt \(Display Type\)](#)

[Send comments about this topic to Microsoft](#)

dv (Display Local Variables)

5/31/2017 • 1 min to read • [Edit Online](#)

The **dv** command displays the names and values of all local variables in the current scope.

```
dv [Flags] [Pattern]
```

Parameters

Flags

Causes additional information to be displayed. Any of the following case-sensitive *Flags* can be included:

/f <addr>

Lets you specify an arbitrary function address so that you can see what parameters and locals exist for any code anywhere. It turns off the value display and implies **/V**. The **/f** flag must be the last flag. A parameter filter pattern can still be specified after it if the string is quoted.

/i

Causes the display to specify the kind of variable: local, global, parameter, function, or unknown.

/t

Causes the display to include the data type for each local variable.

/v

Causes the display to include the virtual memory address or register location of each local variable.

/V

Same as **/v**, and also includes the address of the local variable relative to the relevant register.

/a

Sorts the output by address, in ascending order.

/A

Sorts the output by address, in descending order.

/n

Sorts the output by name, in ascending order.

/N

Sorts the output by name, in descending order.

/z

Sorts the output by size, in ascending order.

/Z

Sorts the output by size, in descending order.

Pattern

Causes the command to only display local variables that match the specified *Pattern*. The pattern may contain a variety of wildcards and specifiers; see [String Wildcard Syntax](#) for details. If *Pattern* contains spaces, it must be enclosed in quotation marks. If *Pattern* is omitted, all local variables will be displayed.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For details on displaying and changing local variables and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

In verbose mode, the addresses of the variables are displayed as well. (This can also be done with the [x \(Examine Symbols\)](#) command.)

Data structures and unfamiliar data types are not displayed in full; rather, their type name is displayed. To display the entire structure, or display a particular member of the structure, use the [dt \(Display Type\)](#) command.

The *local context* determines which set of local variables will be displayed. By default, this context matches the current position of the program counter. For information about how this can be changed, see [Local Context](#).

[Send comments about this topic to Microsoft](#)

dx (Display Debugger Object Model Expression)

5/31/2017 • 21 min to read • [Edit Online](#)

The **dx** command displays a C++ expression using the NatVis extension model. For more information about NatVis, see [Create custom views of native objects in the debugger](#).

```
dx [-g|-gc #][-c #][-n|-v]-r[#] Expression[,<FormatSpecifier> ]  
dx [{-?}|{-h}]
```

Parameters

Expression

A C++ expression to be displayed.

-g

Display as a data grid objects which are iterable. Each iterated element is a row in the grid and each display child of those elements is a column. This allows you to view something such as an array of structs, where each array element is displayed in a row and each field of the struct is displayed in a column.

Left clicking a column name (where there is an available DML link) will sort by that column. If already sorted by that column, the sort order will be inverted.

Any object which is iterable will have a right click context menu item added via DML called 'Display as Grid'. Right clicking an object in the output window and selecting this will display the object in the grid view instead of the standard tree view.

A (+) displayed by a column name offers both a right click and left click behavior.

- Left click takes that column and explodes it into its own table. You see the original rows plus the children of the expanded column.
- Right click provides "Expand Into Grid" which takes the column and adds it back to the current table as right most columns.

-gc #

Display as a grid and restrict grid cell sizes to specified number of (#) characters.

-c #

Displays container continuation (skipping # elements of the container). This option is typically used in custom output automation scenarios and provides a "..." continuation element at the bottom of the listing.

-n

There are two ways that data can be rendered. Using the NatVis visualization (the default) or using the underlying native C/C++ structures. Specify the -n parameter to render the output using just the native C/C++ structures and not the NatVis visualizations.

-v

Display verbose information that includes methods and other non-typical objects.

-r#

Recursively display subtypes (fields) up to # levels. If # is not specified, a recursion level of one, is the default value.

[<FormatSpecifier>]

Use any of the following format specifiers to modify the default rendering.

,x	Display ordinals in hexadecimal
,d	Display ordinals in decimal
,o	Display ordinals in octal
,b	Display ordinals in binary
,en	Display enums by name only (no value)
,c	Display as single character (not a string)
.s	Display 8-bit strings as ASCII quoted
,sb	Display 8-bit strings as ASCII unquoted
,s8	Display 8-bit strings as UTF-8 quoted
,s8b	Display 8-bit strings as UTF-8 unquoted
,su	Display 16-bit strings as UTF-16 quoted
,sub	Display 16-bit strings as UTF-16 unquoted
,!	Display objects in raw mode only (e.g.: no NatVis)
,#	Specify length of pointer/array/container as the literal value # (replace with numeric)
,[<expression>]	Specify length of pointer/array/container as the expression <expression>
,nd	Do not find the derived (runtype) type of the object. Display static value only

dx {-?}

Display command line help.

dx {-h}

Displays help for objects available in the debugger.

Command line usage example

The .dx settings command can be used to display information about the Debug Settings object. For more information about the debug settings objects, see [.settings](#) .

```
kd> dx -r1 Debugger.Settings
Debugger.Settings :
  Display      :
  EngineInitialization :
  Extensions    :
  Input         :
  Sources       :
  Symbols       :
  AutoSaveSettings : false
```

Use the `-r1` recursion option to view the other Debugger objects - Sessions, Settings and State.

```
kd> dx -r1 Debugger
Debugger :
  Sessions :
  Settings :
  State   :
```

Specify the `Debugger.Sessions` object with the `-r3` recursion option to travel further down the object chain.

```
kd> dx -r3 Debugger.Sessions
Debugger.Sessions :
  [0]           : Remote KD: KdSrv:Server=@{<Local>},Trans=@{1394:Channel=0}
  Processes :
    [0]           : <Unknown Image>
    [4]           : <Unknown Image>
    [304]         : smss.exe
    [388]         : csrss.exe
    [456]         : wininit.exe
    [468]         : csrss.exe
    [528]         : services.exe
    [536]         : lsass.exe
    [544]         : winlogon.exe
    [620]         : svchost.exe
    ...
    ...
```

Add the `x` format specifier to display the ordinal values in hexadecimal.

```
kd> dx -r3 Debugger.Sessions,x
Debugger.Sessions,x :
  [0x0]           : Remote KD: KdSrv:Server=@{<Local>},Trans=@{1394:Channel=0}
  Processes :
    [0x0]           : <Unknown Image>
    [0x4]           : <Unknown Image>
    [0x130]         : smss.exe
    [0x184]         : csrss.exe
    [0x1c8]         : wininit.exe
    [0x1d4]         : csrss.exe
    [0x210]         : services.exe
    [0x218]         : lsass.exe
    [0x220]         : winlogon.exe
    [0x26c]         : svchost.exe
    [0x298]         : svchost.exe
    [0x308]         : dwm.exe
    [0x34c]         : nvsvc.exe
    [0x37c]         : nvsvc.exe
    [0x384]         : svchost.exe
    ...
    ...
```

This example uses an active debug session to list the call stack of the first thread in the first process.

```
kd> dx -r1 Debugger.Sessions.First().Processes.First().Threads.First().Stack.Frames
Debugger.Sessions.First().Processes.First().Threads.First().Stack.Frames :
[0x0] : nt!RtlpBreakWithStatusInstruction
[0x1] : nt!KdCheckForDebugBreak + 0x7a006
[0x2] : nt!KiUpdateRunTime + 0x42
[0x3] : nt!KiUpdateTime + 0x129
[0x4] : nt!KeClockInterruptNotify + 0x1c3
[0x5] : hal!HalpTimerClockInterruptEpilogCommon + 0xa
[0x6] : hal!HalpTimerClockInterruptCommon + 0x3e
[0x7] : hal!HalpTimerClockInterrupt + 0x1cb
[0x8] : nt!KiIdleLoop + 0x1a
```

Use the **-g** option to display output as a data grid. Click on a column to sort.

```
kd> dx -g @$curprocess.Modules
```

	BaseAddress	Name	Size
[0x0] : \SystemRoot\System32\drivers\ksecd.dll	0xffffffff8017ca0000	\SystemRoot\System32\drivers\ksecd.dll	0x26000
[0x1] : \SystemRoot\System32\drivers\Clipnp.sys	0xffffffff8017ca30000	\SystemRoot\System32\drivers\clipnp.sys	0x41000

[0x10] : \SystemRoot\System32\drivers\pdc.sys	0xffffffff8017ca7000	\SystemRoot\System32\drivers\pdc.sys	0x1b000

Use the **-h** option to display information about objects.

```
kd> dx -h Debugger.State
Debugger.State [State pertaining to the current execution of the debugger (e.g.: user variables)]
    DebuggerVariables [Debugger variables which are owned by the debugger and can be referenced by a pseudo-
register prefix of @$]
    PseudoRegisters [Categorized debugger managed pseudo-registers which can be referenced by a pseudo-
register prefix of @$]
    UserVariables [User variables which are maintained by the debugger and can be referenced by a
pseudo-register prefix of @$]
```

Working around symbol file limitations with casting

When displaying information about various Windows system variables, there are times where not all of the type information is available in the public symbols. This example illustrates this situation.

```
0: kd> dx nt!PsIdleProcess
Error: No type (or void) for object at Address 0xffff800e1d50128
```

The dx command supports the ability to reference the address of a variable which does not have type information. Such "address of" references are treated as "void *" and can be cast as such. This means that if the data type is known, the following syntax can be used to display type information for the variable.

```
dx (Datatype *)&VariableName
```

For example for a nt!PsIdleProcess which has a data type of nt!_EPROCESS, use this command.

```
dx (nt!_EPROCESS *)&nt!PsIdleProcess
(nt!_EPROCESS *)&nt!PsIdleProcess : 0xffff800e1d50128 [Type: _EPROCESS *]
[+0x000] Pcb [Type: _KPROCESS]
[+0x2c8] ProcessLock [Type: _EX_PUSH_LOCK]
[+0x2d0] CreateTime : {4160749568} [Type: _LARGE_INTEGER]
[+0x2d8] RundownProtect [Type: _EX_RUNDOWN_REF]
[+0x2e0] UniqueProcessId : 0x1000 [Type: void *]
[+0x2e8] ActiveProcessLinks [Type: _LIST_ENTRY]
[+0x2f8] Flags2 : 0x218230 [Type: unsigned long]
[+0x2f8 ( 0: 0)] JobNotReallyActive : 0x0 [Type: unsigned long]
```

The `dx` command does not support switching expression evaluators with the `@@` MASM syntax. For more information about expression evaluators, see [Evaluating Expressions](#).

Custom NatVis object example

Create a simple C++ application that has an instance of the class `CDog`.

```
class CDog
{
public:
    CDog(){m_age = 8; m_weight = 30;}
    long m_age;
    long m_weight;
};

int main()
{
    CDog MyDog;
    printf_s("%d, %d\n", MyDog.m_age, MyDog.m_weight);
    return 0;
}
```

Create a file named `Dog.natvis` that contains this XML:

```
<?xml version="1.0" encoding="utf-8"?>
<AutoVisualizer xmlns="http://schemas.microsoft.com/vstudio/debugger/natvis/2010">
    <Type Name="CDog">
        <DisplayString>{{Age = {m_age} years. Weight = {m_weight} pounds.}}</DisplayString>
    </Type>
</AutoVisualizer>
```

Copy `Dog.natvis` to the `Visualizers` folder in your installation directory for Debugging Tools for Windows. For example:

`C:\Program Files\Debugging Tools for Windows (x64)\Visualizers`

Run your program, and break in at the main function. Take a step so that the variable `MyDog` gets initialized.

Display `MyDog` using `??` and again using `dx`.

```
0:000> ??MyDog
class CDog
    +0x000 m_age : 0n8
    +0x004 m_weight : 0n30
0:000> *
0:000> dx -r1 MyDog
.....
MyDog : {Age = 8 years. Weight = 30 pounds.} [Type: CDog]
```

LINQ

Using LINQ With The dx Command

LINQ syntax can be used with the dx command to search and manipulate data. LINQ is conceptually similar to the Structured Query Language (SQL) that is used to query databases. You can use a number of LINQ methods to search, filter and parse debug data. The LINQ C# method syntax is used. For more information on LINQ and the LINQ C# syntax, see the following MSDN topics:

[LINQ \(Language-Integrated Query\)](#)

[Getting Started with LINQ in C#](#)

Function Objects (Lambda Expressions)

Many of the methods that are used to query data are based on the concept of repeatedly running a user provided function across objects in a collection. To support the ability to query and manipulate data in the debugger, the dx command supports lambda expressions using the equivalent C# syntax. A lambda expression is defined by usage of the => operator as follows:

(arguments) => (result)

To see how LINQ is used with dx, try this simple example to add together 5 and 7.

```
kd> dx ((x, y) => (x + y))(5, 7)
```

The dx command echos back the lambda expression and displays the result of 12.

```
((x, y) => (x + y))(5, 7) : 12
```

This example lambda expression combines the strings "Hello" and "World".

```
kd> dx ((x, y) => (x + y))("Hello", "World")
((x, y) => (x + y))("Hello", "World") : HelloWorld
```

Debugger Objects Examples

Debugger objects are projected into a namespace rooted at "Debugger". Processes, modules, threads, stacks, stack frames, and local variables are all available to be used in a LINQ query.

LINQ commands such as the following can be used .All, .Any, .Count, .First, .Flatten, .GroupBy, .Last, .OrderBy, .OrderByDescending, .Select, and .Where. These methods follow (as closely as possible) the C# LINQ method form.

This example shows the top 5 processes running the most threads:

```

0: kd> dx -r2 Debugger.Sessions.First().Processes.Select(p => new { Name = p.Name, ThreadCount =
p.Threads.Count() }).OrderByDescending(p => p.ThreadCount),5
Debugger.Sessions.First().Processes.Select(p => new { Name = p.Name, ThreadCount = p.Threads.Count()
}).OrderByDescending(p => p.ThreadCount),5

:
[0x4]      :
  Name      : <Unknown Image>
  ThreadCount : 0x73
[0x708]      :
  Name      : explorer.exe
  ThreadCount : 0x2d
[0x37c]      :
  Name      : svchost.exe
  ThreadCount : 0x2c
[0x6b0]      :
  Name      : MsMpEng.exe
  ThreadCount : 0x22
[0x57c]      :
  Name      : svchost.exe
  ThreadCount : 0x15
[...]

```

This example shows the devices in the plug and play device tree grouped by the name of the physical device object's driver. Not all of the output is shown.

```

kd> dx -r2 Debugger.Sessions.First().Devices.DeviceTree.Flatten(n => n.Children).GroupBy(n =>
n.PhysicalDeviceObject->Driver->DriverName.ToDisplayString())
Debugger.Sessions.First().Devices.DeviceTree.Flatten(n => n.Children).GroupBy(n => n.PhysicalDeviceObject-
>Driver->DriverName.ToDisplayString())

:
["\"\\Driver\\PnpManager\"] :
[0x0]      : HTREE\\ROOT\\0
[0x1]      : ROOT\\volmgr\\0000 (volmgr)
[0x2]      : ROOT\\BasicDisplay\\0000 (BasicDisplay)
[0x3]      : ROOT\\CompositeBus\\0000 (CompositeBus)
[0x4]      : ROOT\\vdrvroot\\0000 (vdrvroot)
...

```

Tab Auto Completion

Contextual TAB key auto completion is aware of the LINQ query methods and will work for parameters of lambdas.

As an example, type (or copy and paste) the following text into the debugger. Then hit the TAB key several times to cycle through potential completions.

```

dx -r2 Debugger.Sessions.First().Processes.Select(p => new {Name = p.Name, ThreadCount = p.Threads.Count()
}).OrderByDescending(p => p.

```

Press the TAB key until ".Name" appears. Add a closing parenthesis ")" and press enter to execute the command.

```
kd> dx -r2 Debugger.Sessions.First().Processes.Select(p => new {Name = p.Name, ThreadCount = p.Threads.Count() }).OrderByDescending(p => p.Name)
Debugger.Sessions.First().Processes.Select(p => new {Name = p.Name, ThreadCount = p.Threads.Count() }).OrderByDescending(p => p.Name) :
[0x274]      :
  Name        : winlogon.exe
  ThreadCount : 0x4
[0x204]      :
  Name        : wininit.exe
  ThreadCount : 0x2
[0x6c4]      :
  Name        : taskhostex.exe
  ThreadCount : 0x8
...
...
```

This example shows completion with a key comparator method. The substitution will show string methods, since the key is a string.

```
dx -r2 Debugger.Sessions.First().Processes.Select(p => new {Name = p.Name, ThreadCount = p.Threads.Count() }).OrderByDescending(p => p.Name, (a, b) => a.
```

Press the TAB key until ".Length" appears. Add a closing parenthesis ")" and press enter to execute the command.

```
kd> dx -r2 Debugger.Sessions.First().Processes.Select(p => new {Name = p.Name, ThreadCount = p.Threads.Count() }).OrderByDescending(p => p.Name, (a, b) => a.Length)
Debugger.Sessions.First().Processes.Select(p => new {Name = p.Name, ThreadCount = p.Threads.Count() }).OrderByDescending(p => p.Name, (a, b) => a.Length) :
[0x544]      :
  Name        : spoolsv.exe
  ThreadCount : 0xc
[0x4d4]      :
  Name        : svchost.exe
  ThreadCount : 0xa
[0x438]      :
  Name        : svchost.exe
```

User Defined Variables

A user defined variable can be defined by prefixing the variable name with @\$. A user defined variable can be assigned to anything dx can utilize, for example, lambdas, the results of LINQ queries, etc.

You can create and set the value of a user variable like this.

```
kd> dx @$String1="Test String"
```

You can display the defined user variables using *Debugger.State.UserVariables* or *@\$vars*.

```
kd> dx Debugger.State.UserVariables
Debugger.State.UserVariables :
  mySessionVar      :
  String1          : Test String
```

You can remove a variable using .Remove.

```
kd> dx @$vars.Remove("String1")
```

This example shows how to define a user variable to reference Debugger.Sessions.

```
kd> dx @$mySessionVar = Debugger.Sessions
```

The user defined variable can then be used as shown below.

```
kd> dx -r2 @$mySessionVar
@$mySessionVar  :
[0x0]          : Remote KD:
KdSrv:Server=@{<Local>},Trans=@{COM:Port=\\.\com3,Baud=115200,Timeout=4000}
    Processes    :
    Devices
```

User Defined Variables - Anonymous Types

This creation of dynamic objects is done using the C# anonymous type syntax (new { ... }). For more information see about anonymous types, see [Anonymous Types \(C# Programming Guide\)](#). This example create an anonymous type with an integer and string value.

```
kd> dx -r1 new { MyInt = 42, MyString = "Hello World" }
new { MyInt = 42, MyString = "Hello World" } :
    MyInt          : 42
    MyString       : Hello World
```

System Defined Variables

The following system defined variables can be used in any LINQ dx query.

- @\$cursession - The current session
- @\$curprocess - The current process
- @\$curthread - The current thread

This example show the use of the system defined variables.

```
kd> dx @$curprocess.Threads.Count()
@$curprocess.Threads.Count() : 0x4
```

```
kd> dx -r1 @$curprocess.Threads
@$curprocess.Threads :
[0x4adc]      :
[0x1ee8]      :
[0x51c8]      :
[0x62d8]      :
...
```

Supported LINQ Syntax - Query Methods

Any object which dx defines as iterable (be that a native array, a type which has NatVis written describing it as a container, or a debugger extension object) has a series of LINQ (or LINQ equivalent) methods projected onto it. Those query methods are described below. The signatures of the arguments to the query methods are listed after all of the query methods.

Filtering Methods

.Where (PredicateMethod)	Returns a new collection of objects containing every object in the input collection for which the predicate method returned true.
----------------------------	---

Projection Methods

.Flatten ([KeyProjectorMethod])	Takes an input container of containers (a tree) and flattens it into a single container which has every element in the tree. If the optional key projector method is supplied, the tree is considered a container of keys which are themselves containers and those keys are determined by a call to the projection method.
.Select (KeyProjectorMethod)	Returns a new collection of objects containing the result of calling the projector method on every object in the input collection.

Grouping Methods

.GroupBy (KeyProjectorMethod, [KeyComparatorMethod])	Returns a new collection of collections by grouping all objects in the input collection having the same key as determined by calling the key projector method. An optional comparator method can be provided.
Join (InnerCollection, Outer key selector method, Inner key selector method, Result selector method, [ComparatorMethod])	Joins two sequences based on key selector functions and extracts pairs of values. An optional comparator method can also be specified.
Intersect (InnerCollection, [ComparatorMethod])	Returns the set intersection, which means elements that appear in each of two collections. An optional comparator method can also be specified.
Union (InnerCollection, [ComparatorMethod])	Returns the set union, which means unique elements that appear in either of two collections. An optional comparator method can also be specified.

Data Set Methods

Contains (Object, [ComparatorMethod])	Determines whether a sequence contains a specified element. An optional comparator method can be provided that will be called each time the element is compared against an entry in the sequence.
Distinct ([ComparatorMethod])	Removes duplicate values from a collection. An optional comparator method can be provided to be called each time objects in the collection must be compared.
Except (InnerCollection, [ComparatorMethod])	Returns the set difference, which means the elements of one collection that do not appear in a second collection. An optional comparator method can be specified.
Concat (InnerCollection)	Concatenates two sequences to form one sequence.

Ordering Methods

.OrderBy (KeyProjectorMethod, [KeyComparatorMethod])	Sorts the collection in ascending order according to a key as provided by calling the key projection method on every object in the input collection. An optional comparator method can be provided.
.OrderByDescending (KeyProjectorMethod, [KeyComparatorMethod])	Sorts the collection in descending order according to a key as provided by calling the key projection method on every object in the input collection. An optional comparator method can be provided.

Aggregating Methods

Count ()	A method that returns the number of elements in the collection.
Sum ([ProjectionMethod])	Calculates the sum of the values in a collection. Can optionally specify a projector method to transform the elements before summation occurs.

Skip Methods

Skip (Count)	Skips elements up to a specified position in a sequence.
SkipWhile (PredicateMethod)	Skips elements based on a predicate function until an element does not satisfy the condition.

Take Methods

Take (Count)	Takes elements up to a specified position in a sequence.
TakeWhile (PredicateMethod)	Takes elements based on a predicate function until an element does not satisfy the condition.

Comparison Methods

SequenceEqual (InnerCollection, [ComparatorMethod])	Determines whether two sequences are equal by comparing elements in a pair-wise manner. An optional comparator can be specified.
---	--

Error Handling Methods

AllNonError (PredicateMethod)	Returns whether all non-error elements of a collection satisfy a given condition.
FirstNonError ([PredicateMethod])	Returns the first element of a collection that isn't an error.

LastNonError ([PredicateMethod])	Returns the last element of a collection that isn't an error.
----------------------------------	---

Other Methods

.All (PredicateMethod)	Returns whether the result of calling the specified predicate method on every element in the input collection is true.
.Any (PredicateMethod)	Returns whether the result of calling the specified predicate method on any element in the input collection is true.
.First ([PredicateMethod])	Returns the first element in the collection. If the optional predicate is passed, returns the first element in the collection for which a call to the predicate returns true.
.Last ([PredicateMethod])	Returns the last element in the collection. If the optional predicate is passed, returns the last element in the collection for which a call to the predicate returns true.
Min([KeyProjectorMethod])	Returns the minimum element of the collection. An optional projector method can be specified to project each method before it is compared to others.
Max([KeyProjectorMethod])	Returns the maximum element of the collection. An optional projector method can be specified to project each method before it is compared to others.
Single([PredicateMethod])	Returns the only element from the list (or an error if the collection contains more than one element). If a predicate is specified, returns the single element that satisfies that predicate (if more than one element satisfies it, the function returns an error instead).

Signatures of the Arguments

KeyProjectorMethod : (obj => arbitrary key)	Takes an object of the collection and returns a key from that object.
KeyComparatorMethod: ((a, b) => integer value)	Takes two keys and compares them returning: -1 if (a < b) 0 if (a == b) 1 if (a > b)
PredicateMethod: (obj => boolean value)	Takes an object of the collection and returns true or false based on whether that object meets certain criteria.

Supported LINQ Syntax - String Manipulation

All string objects have the following methods projected into them, so that they are available for use:

Query Relevant Methods & Properties

.Contains (OtherString)	Returns a boolean value indicating whether the input string contains OtherString.
.EndsWith (OtherString)	Returns a boolean value indicating whether the input string ends with OtherString.
Length	A property which returns the length of the string.
.StartsWith (OtherString)	Returns a boolean value indicating whether the input string starts with OtherString.
.Substring (StartPos, [Length])	Returns a substring within the input string starting at the given starting position. If the optional length is supplied, the returned substring will be of the specified length; otherwise – it will go to the end of the string.

Miscellaneous Methods

.IndexOf (OtherString)	Returns the index of the first occurrence of OtherString within the input string.
.LastIndexOf (OtherString)	Returns the index of the last occurrence of OtherString within the input string.

Formatting Methods

.PadLeft (TotalWidth)	Adds spaces as necessary to the left side of the string in order to bring the total length of the string to the specified width.
.PadRight (TotalWidth)	Adds spaces as necessary to the right side of the string in order to bring the total length of the string to the specified width.
.Remove (StartPos, [Length])	Removes characters from the input string starting at the specified starting position. If the optional length parameter is supplied, that number of characters will be removed; otherwise – all characters to the end of the string will be removed.
.Replace (SearchString, ReplaceString)	Replaces every occurrence of SearchString within the input string with the specified ReplaceString.

String Object Projections

In addition to the methods which are projected directly onto string objects, any object which itself has a string conversion has the following method projected onto it, making it method available for use:

```
.ToDisplayString()
```

Returns a string conversion of the object. This is the string conversion which would be shown in a dx invocation for the object. You can provide a formatting specifier to format the output of ToDisplayString.

The following examples illustrate the use of format specifiers.

```
kd> dx (10).ToDisplayString("d")
(10).ToDisplayString("d") : 10

kd> dx (10).ToDisplayString("x")
(10).ToDisplayString("x") : 0xa

kd> dx (10).ToDisplayString("o")
(10).ToDisplayString("o") : 012

kd> dx (10).ToDisplayString("b")
(10).ToDisplayString("b") : 0y1010
```

Debugging Plug and Play

This section illustrates how the built in debugger objects used with LINQ queries, can be used to debug plug and play objects.

View all devices

Use *Flatten* on the device tree to view all devices.

```
1: kd> dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children)
@$cursession.Devices.DeviceTree.Flatten(n => n.Children)
[0x0]      : HTREE\ROOT\0
[0x1]      : ROOT\volmgr\0000 (volmgr)
[0x2]      : ROOT\BasicDisplay\0000 (BasicDisplay)
[0x3]      : ROOT\CompositeBus\0000 (CompositeBus)
[0x4]      : ROOT\vdrvroot\0000 (vdrvroot)
[0x5]      : ROOT\spaceport\0000 (spaceport)
[0x6]      : ROOT\KDNIC\0000 (kdnic)
[0x7]      : ROOT\UMBUS\0000 (umbus)
[0x8]      : ROOT\ACPI_HAL\0000
...
```

Grid Display

As with other dx commands, you can right click on a command after it was executed and click "Display as grid" or add "-g" to the command to get a grid view of the results.

```
# 0: kd> dx -g @$cursession.Devices.DeviceTree.Flatten(n => n.Children)
=====
=====
=====
# = = (+) DeviceNodeObject = InstancePath
= ServiceName = (+) PhysicalDeviceObject = State
= (+) Resoures = (+) Children =
=====
=====
=====
= [0x0] : HTREE\ROOT\0 - {...} - HTREE\ROOT\0
- 0xfffffb6075614be40 : Device for "\Driver\PnpManager" -
DeviceNodeStarted (776) - {...} - [object Object] =
= [0x1] : ROOT\volmgr\0000 (volmgr) - {...} - ROOT\volmgr\0000
- volmgr - 0xfffffb607561fbe40 : Device for "\Driver\PnpManager" -
DeviceNodeStarted (776) - {...} - [object Object] =
= [0x2] : ROOT\BasicDisplay\0000 (BasicDisplay) - {...} -
ROOT\BasicDisplay\0000 - BasicDisplay -
0xfffffb607560739b0 : Device for "\Driver\PnpManager" - DeviceNodeStarted (776) - {...}
- [object Object] =
= [0x3] : ROOT\CompositeBus\0000 (CompositeBus) - {...} -
ROOT\CompositeBus\0000 - CompositeBus -
0xfffffb607561f9060 : Device for "\Driver\PnpManager" - DeviceNodeStarted (776) - {...}
- [object Object] =
...
...
```

View Devices by State

Use *Where* to specify a specific device state.

```
dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.State <operator> <state number>)
```

For example to view devices in state DeviceNodeStarted use this command.

```
1: kd> dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.State == 776)
@$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.State == 776)
[0x0] : HTREE\ROOT\0
[0x1] : ROOT\volmgr\0000 (volmgr)
[0x2] : ROOT\BasicDisplay\0000 (BasicDisplay)
[0x3] : ROOT\CompositeBus\0000 (CompositeBus)
[0x4] : ROOT\vdrvroot\0000 (vdrvroot)
...
```

View Not Started Devices

Use this command to view devices not in state DeviceNodeStarted.

```
1: kd> dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.State != 776)
@$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.State != 776)
[0x0] : ACPI\PNP0C01\1
[0x1] : ACPI\PNP0000\4&215d0f95&0
[0x2] : ACPI\PNP0200\4&215d0f95&0
[0x3] : ACPI\PNP0100\4&215d0f95&0
[0x4] : ACPI\PNP0800\4&215d0f95&0
[0x5] : ACPI\PNP0C04\4&215d0f95&0
[0x6] : ACPI\PNP0700\4&215d0f95&0 (fdc)
[0x7] : ACPI\PNP0C02\1
[0x8] : ACPI\PNP0C02\2
```

View Devices by Problem Code

Use the `DeviceNodeObject.Problem` object to view devices that have specific problem codes.

```
dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.DeviceNodeObject.Problem <operator> <problemCode>)
```

For example, to view devices that have a non zero problem code use this command. This provides similar information to "[!devnode 0 21](#)".

```
1: kd> dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.DeviceNodeObject.Problem != 0)
@$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.DeviceNodeObject.Problem != 0)
[0x0]      : HTREE\ROOT\0
[0x1]      : ACPI\PNP0700\4&215d0f95&0 (fdc)
```

View All Devices Without a Problem

Use this command to view all devices without a problem

```
1: kd> dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.DeviceNodeObject.Problem == 0)
@$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.DeviceNodeObject.Problem == 0)
[0x0]      : ROOT\volmgr\0000 (volmgr)
[0x1]      : ROOT\BasicDisplay\0000 (BasicDisplay)
[0x2]      : ROOT\CompositeBus\0000 (CompositeBus)
[0x3]      : ROOT\vdrvroot\0000 (vdrvroot)
...
```

View All Devices With a Specific Problem

Use this command to view devices with a problem state of 0x16.

```
1: kd> dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.DeviceNodeObject.Problem == 0x16)
@$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.DeviceNodeObject.Problem == 0x16)
[0x0]      : HTREE\ROOT\0
[0x1]      : ACPI\PNP0700\4&215d0f95&0 (fdc)
```

View Devices by Function Driver

Use this command to view devices by function driver.

```
dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.ServiceName <operator> <serviceName>)
```

To view devices using a certain function driver, such as atapi, use this command.

```
1: kd> dx @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.ServiceName == "atapi")
@$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n => n.ServiceName == "atapi")
[0x0]      : PCIIDE\IDEChannel\4&10bf2f88&0&0 (atapi)
[0x1]      : PCIIDE\IDEChannel\4&10bf2f88&0&1 (atapi)
```

Viewing a List of Boot Start Drivers

To view the list of what winload loaded as boot start drivers, you need to be in a context where you have access

to the LoaderBlock and early enough the LoaderBlock is still around. For example, during nt!IoInitializeBootDrivers. A breakpoint can be set to stop in this context.

```
1: kd> g
Breakpoint 0 hit
nt!IoInitializeBootDrivers:
8225c634 8bff      mov     edi,edi
```

Use the ?? command to display the boot driver structure.

```
1: kd> ?? LoaderBlock->BootDriverListHead
struct _LIST_ENTRY
[ 0x808c9960 - 0x808c8728 ]
+0x000 Flink      : 0x808c9960 _LIST_ENTRY [ 0x808c93e8 - 0x808a2e18 ]
+0x004 Blink      : 0x808c8728 _LIST_ENTRY [ 0x808a2e18 - 0x808c8de0 ]
```

Use the Debugger.Utility.Collections.FromListEntry debugger object to view of the data, using the starting address of the nt!_LIST_ENTRY structure.

```
1: kd> dx Debugger.Utility.Collections.FromListEntry(*(nt!_LIST_ENTRY *)0x808c9960,
"nt!_BOOT_DRIVER_LIST_ENTRY", "Link")
Debugger.Utility.Collections.FromListEntry(*(nt!_LIST_ENTRY *)0x808c9960, "nt!_BOOT_DRIVER_LIST_ENTRY",
"Link")
[0x0]      [Type: _BOOT_DRIVER_LIST_ENTRY]
[0x1]      [Type: _BOOT_DRIVER_LIST_ENTRY]
[0x2]      [Type: _BOOT_DRIVER_LIST_ENTRY]
[0x3]      [Type: _BOOT_DRIVER_LIST_ENTRY]
[0x4]      [Type: _BOOT_DRIVER_LIST_ENTRY]
[0x5]      [Type: _BOOT_DRIVER_LIST_ENTRY]
...
...
```

Use the -g option to create a grid view of the data.

```
dx -r1 -g Debugger.Utility.Collections.FromListEntry(*(nt!_LIST_ENTRY *)0x808c9960,
"nt!_BOOT_DRIVER_LIST_ENTRY", "Link")
```

View devices by Capability

View devices by capability using the DeviceNodeObject.CapabilityFlags object.

```
dx -r1 @$cursession.Devices.DeviceTree.Flatten(n => n.Children).Where(n =>
(n.DeviceNodeObject.CapabilityFlags & <flag>) != 0)
```

This table summarizes the use of the dx command with common device capability flags.

Removable

```
0: kd> dx -r1
@$cursession.Devices.DeviceTree.Flatten(n =>
n.Children).Where(n =>
(n.DeviceNodeObject.CapabilityFlags & 0x10) != 0)
@$cursession.Devices.DeviceTree.Flatten(n =>
n.Children).Where(n =>
(n.DeviceNodeObject.CapabilityFlags & 0x10) != 0)
[0x0] : SWD\PRINTENUM\{2F8DBBB6-F246-4D84-BB1D-

e, ea, eb, ed, eD, ef, ep, eq, eu, ew, eza (Enter Values)

5/31/2017 • 2 min to read • [Edit Online](#)

The **e*** commands enter into memory the values that you specify.

This command should not be confused with the [~E \(Thread-Specific Command\)](#) qualifier.

```
e{b|d|D|f|p|q|w} Address [Values]
e{a|u|za|zu} Address "String"
e Address [Values]
```

Parameters

Syntax eD ef

Address

Specifies the starting address where to enter values. The debugger replaces the value at *Address* and each subsequent memory location until all *Values* have been used.

Values

Specifies one or more values to enter into memory. Multiple numeric values should be separated with spaces. If you do not specify any values, the current address and the value at that address will be displayed, and you will be prompted for input.

String

Specifies a string to be entered into memory. The **ea** and **eza** commands will write this to memory as an ASCII string; the **eu** and **ezu** commands will write this to memory as a Unicode string. The **eza** and **ezu** commands write a terminal **NULL**; the **ea** and **eu** commands do not. *String* must be enclosed in quotation marks.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

This command exists in the following forms. The second characters of the **ed** and **eD** commands are case-sensitive.

COMMAND	ENTER
e	This enters data in the same format as the most recent e command. (If the most recent e command was ea , eza , eu , or ezu , the final parameter will be <i>String</i> and may not be omitted.)
ea	ASCII string (not NULL-terminated).
eb	Byte values.
ed	Double-word values (4 bytes).
eD	Double-precision floating-point numbers (8 bytes).
ef	Single-precision floating-point numbers (4 bytes).
ep	Pointer-sized values. This command is equivalent to ed or eq , depending on whether the target computer's processor architecture is 32-bit or 64-bit, respectively.
eq	Quad-word values (8 bytes).
eu	Unicode string (not NULL-terminated).
ew	Word values (2 bytes).
eza	NULL-terminated ASCII string.
ezu	NULL-terminated Unicode string.

Numeric values will be interpreted as numbers in the current radix (16, 10, or 8). To change the default radix, use the **n (Set Number Base)** command. The default radix can be overridden by specifying the **0x** prefix (hexadecimal), the **0n** prefix (decimal), the **0t** prefix (octal), or the **0y** prefix (binary).

Note The default radix behaves differently when C++ expressions are being used. See [Evaluating Expressions](#) for details.

When entering byte values with the **eb** command, you can use single straight quotation marks to specify characters. If you want to include multiple characters, each must be surrounded with its own quotation marks. This allows you to enter a character string that is not terminated by a null character. For example:

```
eb 'h' 'e' 'l' 'l' 'o'
```

C-style escape characters (such as '\0' or '\n') may not be used with these commands.

If you omit the *Values* parameter, you will be prompted for input. The address and its current contents will be displayed, and an **Input>** prompt will appear. You can then do any of the following:

- Enter a new value, by typing the value and pressing ENTER.
- Preserve the current value in memory by pressing SPACE followed by ENTER.
- Exit from the command by pressing ENTER.

[Send comments about this topic to Microsoft](#)

f, fp (Fill Memory)

5/31/2017 • 2 min to read • [Edit Online](#)

The **f** and **fp** commands fill the specified memory range with a repeating pattern.

These commands should not be confused with the [~F \(Freeze Thread\)](#) command.

```
f Range Pattern
fp [MemoryType] PhysicalRange Pattern
```

Parameters

Range

Specifies the range in virtual memory to fill. For more syntax details, see [Address and Address Range Syntax](#).

PhysicalRange

(Kernel mode only) Specifies the range in physical memory to fill. The syntax of *PhysicalRange* is the same as that of a virtual memory range, except that no symbol names are permitted.

MemoryType

(Kernel mode only) Specifies the type of physical memory, which can be one of the following:

[c]

Cached memory.

[uc]

Uncached memory.

[wc]

Write-combined memory.

Pattern

Specifies one or more byte values with which to fill memory.

Environment

Modes	f : user mode, kernel mode fp : kernel mode only
Targets	live, crash dump
Platforms	all

Additional Information

For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

This command fills the memory area specified by *range* with the specified *pattern*, repeated as many times as necessary.

The *pattern* parameter must be input as a series of bytes. These can be entered as numeric or as ASCII characters.

Numeric values will be interpreted as numbers in the current radix (16, 10, or 8). To change the default radix, use the **n (Set Number Base)** command. The default radix can be overridden by specifying the **0x** prefix (hexadecimal), the **0n** prefix (decimal), the **0t** prefix (octal), or the **0y** prefix (binary).

Note The default radix behaves differently when C++ expressions are being used. For more information, see the [Evaluating Expressions](#) topic.

If ASCII characters are used, each character must be enclosed in single straight quotation marks. C-style escape characters (such as '\0' or '\n') may not be used.

If multiple bytes are specified, they must be separated by spaces.

If *pattern* has more values than the number of bytes in the range, the debugger ignores the extra values.

Here are some examples. Assuming the current radix is 16, the following command will fill memory locations 0012FF40 through 0012FF5F with the pattern "ABC", repeated several times:

```
0:000> f 0012ff40 L20 'A' 'B' 'C'
```

The following command has the exact same effect:

```
0:000> f 0012ff40 L20 41 42 43
```

The following examples show how you can use the physical memory types (**c**, **uc**, and **wc**) with the **fp** command in kernel mode:

```
kd> fp [c] 0012ff40 L20 'A' 'B' 'C'
```

```
kd> fp [uc] 0012ff40 L20 'A' 'B' 'C'
```

```
kd> fp [wc] 0012ff40 L20 'A' 'B' 'C'
```

[Send comments about this topic to Microsoft](#)

g (Go)

5/31/2017 • 1 min to read • [Edit Online](#)

The **g** command starts executing the given process or thread. Execution will halt at the end of the program, when *BreakAddress* is hit, or when another event causes the debugger to stop.

User-Mode Syntax

```
[~Thread] g[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]
```

Kernel-Mode Syntax

```
g[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]
```

Parameters

Thread

(User mode only) Specifies the thread to execute. For syntax details, see [Thread Syntax](#).

a

Causes any breakpoint created by this command to be a processor breakpoint (like those created by **ba**) rather than a software breakpoint (like those created by **bp** and **bm**). If *BreakAddress* is not specified, no breakpoint is created and the **a** flag has no effect.

StartAddress

Specifies the address where execution should begin. If this is not specified, the debugger passes execution to the address specified by the current value of the instruction pointer. For more syntax details, see [Address and Address Range Syntax](#).

BreakAddress

Specifies the address for a breakpoint. If *BreakAddress* is specified, it must specify an instruction address (that is, the address must contain the first byte of an instruction). Up to ten break addresses, in any order, can be specified at one time. If *BreakAddress* cannot be resolved, it is stored as an [unresolved breakpoint](#). For more syntax details, see [Address and Address Range Syntax](#).

BreakCommands

Specifies one or more commands to be automatically executed when the breakpoint specified by *BreakAddress* is hit. The *BreakCommands* parameter must be preceded by a semicolon. If multiple *BreakAddress* values are specified, *BreakCommands* applies to all of them.

Note The *BreakCommands* parameter is only available when you are embedding this command within a command string used by another command -- for example, within another breakpoint command or within an except or event setting. On a command line, the semicolon will terminate the **g** command, and any additional commands listed after the semicolon will be executed immediately after the **g** command is done.

Environment

Modes

user mode, kernel mode

Targets	live debugging only
Platforms	all

Additional Information

For other methods of issuing this command and an overview of related commands, see [Controlling the Target](#).

Remarks

If *Thread* is specified, then the **g** command is executed with the specified thread unfrozen and all others frozen. For example, if the **~123g**, **~#g**, or **~*g** command is specified, the specified threads are unfrozen and all others are frozen.

[Send comments about this topic to Microsoft](#)

gc (Go from Conditional Breakpoint)

5/31/2017 • 1 min to read • [Edit Online](#)

The **gc** command resumes execution from a conditional breakpoint in the same fashion that was used to hit the breakpoint (stepping, tracing, or freely executing).

```
gc
```

Environment

Modes	user mode, kernel mode
Targets	live debugging only
Platforms	all

Additional Information

For an overview of related commands, see [Controlling the Target](#).

Remarks

When a [conditional breakpoint](#) includes an execution command at the end, this should be the **gc** command.

For example, the following is a proper conditional breakpoint formulation:

```
0:000> bp Address "j (Condition) 'OptionalCommands'; 'gc' "
```

When this breakpoint is encountered and the expression is false, execution will resume using the same execution type that was previously used. For example, if you used a **g (Go)** command to reach this breakpoint, execution would resume freely. But if you reached this breakpoint while stepping or tracing, execution would resume with a step or a trace.

On the other hand, the following is an improper breakpoint formulation, since execution will always resume freely even if you had been stepping before reaching the breakpoint:

```
0:000> bp Address "j (Condition) 'OptionalCommands'; 'g' "
```

[Send comments about this topic to Microsoft](#)

gh (Go with Exception Handled)

5/31/2017 • 2 min to read • [Edit Online](#)

The **gh** command marks the given thread's exception as having been handled and allows the thread to restart execution at the instruction that caused the exception.

User-Mode Syntax

```
[~Thread] gh[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]
```

Kernel-Mode Syntax

```
gh[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]
```

Parameters

Thread

(User mode only) Specifies the thread to execute. This thread must have been stopped by an exception. For syntax details, see [Thread Syntax](#).

a

Causes any breakpoint created by this command to be a processor breakpoint (like those created by **ba**) rather than a software breakpoint (like those created by **bp** and **bm**). If *BreakAddress* is not specified, no breakpoint is created and the **a** flag has no effect.

StartAddress

Specifies the address at which execution should begin. If this is not specified, the debugger passes execution to the address where the exception occurred. For more syntax details, see [Address and Address Range Syntax](#).

BreakAddress

Specifies the address for a breakpoint. If *BreakAddress* is specified, it must specify an instruction address (that is, the address must contain the first byte of an instruction). Up to ten break addresses, in any order, can be specified at one time. If *BreakAddress* cannot be resolved, it is stored as an [unresolved breakpoint](#). For more syntax details, see [Address and Address Range Syntax](#).

BreakCommands

Specifies one or more commands to be automatically executed when the breakpoint specified by *BreakAddress* is hit. The *BreakCommands* parameter must be preceded by a semicolon. If multiple *BreakAddress* values are specified, *BreakCommands* applies to all of them.

Note The *BreakCommands* parameter is only available when you are embedding this command within a command string used by another command -- for example, within another breakpoint command or within an except or event setting. On a command line, the semicolon will terminate the **gh** command, and any additional commands listed after the semicolon will be executed immediately after the **gh** command is done.

Environment

Modes	user mode, kernel mode
-------	------------------------

Targets	live debugging only
Platforms	all

Additional Information

For other methods of issuing this command and an overview of related commands, see [Controlling the Target](#).

Remarks

If you use the *BreakAddress* parameter to set a breakpoint, this new breakpoint will only be triggered by the current thread. Other threads that execute the code at that location will not be stopped.

If *Thread* is specified, then the **gh** command is executed with the specified thread unfrozen and all others frozen. For example, if the **~123gh**, **~#gh**, or **~*gh** command is specified, the specified threads are unfrozen and all others are frozen.

[Send comments about this topic to Microsoft](#)

gn, gN (Go with Exception Not Handled)

5/31/2017 • 2 min to read • [Edit Online](#)

The **gn** and **gN** commands continue execution of the given thread without marking the exception as having been handled. This allows the application's exception handler to handle the exception.

User-Mode Syntax

```
[~Thread] gn[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]  
[~Thread] gN[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]
```

Kernel-Mode Syntax

```
gn[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]  
gN[a] [= StartAddress] [BreakAddress ... [; BreakCommands]]
```

Parameters

Thread

(User mode only) Specifies the thread to execute. This thread must have been stopped by an exception. For syntax details, see [Thread Syntax](#).

a

Causes any breakpoint created by this command to be a processor breakpoint (like those created by **ba**) rather than a software breakpoint (like those created by **bp** and **bm**). If *BreakAddress* is not specified, no breakpoint is created and the **a** flag has no effect.

StartAddress

Specifies the address where execution should begin. If this is not specified, the debugger passes execution to the address where the exception occurred. For more syntax details, see [Address and Address Range Syntax](#).

BreakAddress

Specifies the address for a breakpoint. If *BreakAddress* is specified, it must specify an instruction address (that is, the address must contain the first byte of an instruction). Up to ten break addresses, in any order, can be specified at one time. If *BreakAddress* cannot be resolved, it is stored as an [unresolved breakpoint](#). For more syntax details, see [Address and Address Range Syntax](#).

BreakCommands

Specifies one or more commands to be automatically executed when the breakpoint specified by *BreakAddress* is hit. The *BreakCommands* parameter must be preceded by a semicolon. If multiple *BreakAddress* values are specified, *BreakCommands* applies to all of them.

Note The *BreakCommands* parameter is only available when you are embedding this command within a command string used by another command -- for example, within another breakpoint command or within an except or event setting. On a command line, the semicolon will terminate the command, and any additional commands listed after the semicolon will be executed immediately after the **gn** or **gN** command is done.

Environment

Modes	user mode, kernel mode

Targets	live debugging only
Platforms	all

Additional Information

For other methods of issuing this command and an overview of related commands, see [Controlling the Target](#).

Remarks

If the debugger is not stopped at a breakpoint, **gn** and **gN** behave identically. If the debugger is stopped at a breakpoint, **gn** will not work; you must capitalize the "N" to execute this command. This is a safety precaution, since it is rarely wise to continue a breakpoint unhandled.

If you use the *BreakAddress* parameter to set a breakpoint, this new breakpoint will only be triggered by the current thread. Other threads that execute the code at that location will not be stopped.

If *Thread* is specified, then the **gn** command is executed with the specified thread unfrozen and all others frozen. For example, if the **~123gn**, **~#gn**, or **~*gn** command is specified, the specified threads are unfrozen and all others are frozen.

[Send comments about this topic to Microsoft](#)

gu (Go Up)

5/31/2017 • 1 min to read • [Edit Online](#)

The **gu** command causes the target to execute until the current function is complete.

User-Mode Syntax

```
[~Thread] gu
```

Kernel-Mode Syntax

```
gu
```

Parameters

Thread

(User mode only) Specifies the thread to execute. This thread must have been stopped by an exception. For syntax details, see [Thread Syntax](#).

Environment

Modes	user mode, kernel mode
Targets	live debugging only
Platforms	all

Additional Information

For other methods of issuing this command and an overview of related commands, see [Controlling the Target](#).

Remarks

The **gu** command executes the target until the current function call returns.

If the current function is called recursively, the **gu** command will not halt execution until the *current instance* of the current function returns. In this way, **gu** differs from **g @\$ra**, which will halt any time the return address of this function is hit.

Note The **gu** command distinguishes different instances of a function by measuring the call stack depth. Executing this command in assembly mode after the arguments have been pushed to the stack and just before the call is made may cause this measurement to be incorrect. Function returns that are optimized away by the compiler may similarly cause this command to stop at the wrong instance of this return. These errors are rare, and can only happen during recursive function calls.

If *Thread* is specified, then the **gu** command is executed with the specified thread unfrozen and all others frozen. For example, if the **~123gu**, **~#gu**, or **~*gu** command is specified, the specified threads are unfrozen and all others are frozen.

Send comments about this topic to Microsoft

ib, iw, id (Input from Port)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ib**, **iw**, and **id** commands read and display a byte, word, or double word from the selected port.

```
ib Address
iw Address
id Address
```

Parameters

Address

The address of the port.

Environment

Modes	Kernel mode only
Targets	Live debugging only
Platforms	x86-based computer only

Remarks

The **ib** command reads a single byte, the **iw** command reads a word, and the **id** command reads a double word.

Make sure that reading an I/O port does not affect the behavior of the device that you are reading from. Some devices change state after a read-only port has been read. You should also not try to read a word or double-word from a port that does not allow values of this length.

See also

[ob, od, ow \(Output to Port\)](#)

[Send comments about this topic to Microsoft](#)

j (Execute If - Else)

5/31/2017 • 1 min to read • [Edit Online](#)

The **j** command conditionally executes one of the specified commands, depending on the evaluation of a given expression.

```
j Expression Command1 ; Command2
j Expression 'Command1' ; 'Command2'
```

Parameters

Expression

The expression to evaluate. If this expression evaluates to a nonzero value, *Command1* is executed. If this expression evaluates to zero, *Command2* is executed. For more information about the syntax of this expression, see [Numerical Expression Syntax](#).

Command1

The command string to be executed if the expression in *Expression* evaluates to a nonzero value (TRUE). You can combine multiple commands by surrounding the command string with single straight quotation marks (') and separating commands by using semicolons. If the command string is a single command, the single quotation marks are optional.

Command2

The command string to be executed if the expression in *Expression* evaluates to zero (FALSE). You can combine multiple commands by surrounding the command string with single straight quotation marks (') and separating commands by using semicolons. If the command string is a single command, the single quotation marks are optional.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

You cannot add a semicolon or additional commands after the **j** command. If a semicolon appears after *Command2*, everything after the semicolon is ignored.

The following command displays the value of **eax** if **MySymbol** is equal to zero and displays the values of **ebx** and **ecx** otherwise.

```
0:000> j (MySymbol=0) 'r eax'; 'r ebx; r ecx'
```

You could omit the single quotation marks around **r eax**, but they make the command easier to read. If you want

to omit one of the commands, you can include empty quotation marks or omit the parameter for that command, as in the following commands.

```
0:000> j (MySymbol=0) ''; 'r ebx; r ecx'  
0:000> j (MySymbol=0) ; 'r ebx; r ecx'
```

You can also use the **j** command inside other commands. For example, you can use a **j** command to create conditional breakpoints.

```
0:000> bp `mysource.cpp:143` "j (poi(MyVar)>0n20) ''; 'gc' "
```

For more information about the syntax for conditional breakpoints, see [Setting a Conditional Breakpoint](#).

[z \(Execute While\)](#)

[Send comments about this topic to Microsoft](#)

k, kb, kc, kd, kp, kP, kv (Display Stack Backtrace)

5/31/2017 • 5 min to read • [Edit Online](#)

The **k***** commands display the stack frame of the given thread, together with related information..

User-Mode, x86 Processor

```
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] [FrameCount]
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] = BasePtr [FrameCount]
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] = BasePtr StackPtr InstructionPtr
[~Thread] kd [WordCount]
```

Kernel-Mode, x86 Processor

```
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] [FrameCount]
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr FrameCount
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] = BasePtr StackPtr InstructionPtr
[Processor] kd [WordCount]
```

User-Mode, x64 Processor

```
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] [FrameCount]
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr FrameCount
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr InstructionPtr FrameCount
[~Thread] kd [WordCount]
```

Kernel-Mode, x64 Processor

```
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] [FrameCount]
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr FrameCount
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr InstructionPtr FrameCount
[Processor] kd [WordCount]
```

User-Mode, ARM Processor

```
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] [FrameCount]
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr FrameCount
[~Thread] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr InstructionPtr FrameCount
[~Thread] kd [WordCount]
```

Kernel-Mode, ARM Processor

```
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] [FrameCount]
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr FrameCount
[Processor] k[b|p|P|v] [c] [n] [f] [L] [M] = StackPtr InstructionPtr FrameCount
[Processor] kd [WordCount]
```

Parameters

Thread

Specifies the thread whose stack is to be displayed. If you omit this parameter, the stack of the current thread is displayed. For more information about thread syntax, see [Thread Syntax](#). You can specify threads only in user mode.

Processor

Specifies the processor whose stack is to be displayed. For more information about processor syntax, see [Multiprocessor Syntax](#).

b

Displays the first three parameters that are passed to each function in the stack trace.

c

Displays a clean stack trace. Each display line includes only the module name and the function name.

p

Displays all of the parameters for each function that is called in the stack trace. The parameter list includes each parameter's data type, name, and value. The p option is case sensitive. This parameter requires full symbol information.

P

Displays all of the parameters for each function that is called in the stack trace, like the p parameter. However, for P, the function parameters are printed on a second line of the display, instead of on the same line as the rest of the data.

v

Displays frame pointer omission (FPO) information. On x86-based processors, the display also includes calling convention information.

n

Displays frame numbers.

f

Displays the distance between adjacent frames. This distance is the number of bytes that separate the frames on the actual stack.

L

Hides source lines in the display. L is case sensitive.

M

Displays output using [Debugger Markup Language](#). Each frame number in the display is a link that you can click to set the local context and display local variables. For information about the local context, see [.frame](#).

FrameCount

Specifies the number of stack frames to display. You should specify this number in hexadecimal format, unless you have changed the radix by using the [n \(Set Number Base\)](#) command. The default value is 20 (0x14), unless you have changed the default value by using the [.kframes \(Set Stack Length\)](#) command.

BasePtr

Specifies the base pointer for the stack trace. The *BasePtr* parameter is available only if there is an equal sign (=) after the command.

StackPtr

Specifies the stack pointer for the stack trace. If you omit *StackPtr* and *InstructionPtr*, the command uses the stack pointer that the rsp (or esp) register specifies and the instruction pointer that the rip (or eip) register specifies.

InstructionPtr

Specifies the instruction pointer for the stack trace. If you omit *StackPtr* and *InstructionPtr*, the command uses the stack pointer that the *rsp* (or *esp*) register specifies and the instruction pointer that the *rip* (or *eip*) register specifies.

WordCount

Specifies the number of *DWORD_PTR* values in the stack to dump. The default value is 20 (0x14), unless you changed the default value by using the [.kframes \(Set Stack Length\)](#) command.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

Remarks

When you issue the **k**, **kb**, **kp**, **kP**, or **kv** command, a stack trace is displayed in a tabular format. If line loading is enabled, source modules and line numbers are also displayed.

The stack trace includes the base pointer for the stack frame, the return address, and function names.

If you use the **kp** or **kP** command, the full parameters for each function that is called in the stack trace are displayed. The parameter list includes each parameter's data type, name, and value.

This command might be slow. For example, when **MyFunction1** calls **MyFunction2**, the debugger must have full symbol information for **MyFunction1** to display the parameters that are passed in this call. This command does not fully display internal Microsoft Windows routines that are not exposed in public symbols.

If you use the **kb** or **kv** command, the first three parameters that are passed to each function are displayed. If you use the **kv** command, FPO data is also displayed.

On an x86-based processor, the **kv** command also displays calling convention information.

When you use the **kv** command, the FPO information is added at the end of the line in the following format.

FPO TEXT	MEANING
FPO: [non-Fpo]	No FPO data for the frame.
FPO: [N1,N2,N3]	<p><i>N1</i> is the total number of parameters.</p> <p><i>N2</i> is the number of <i>DWORD</i> values for the local variables.</p> <p><i>N3</i> is the number of registers that are saved.</p>

FPO TEXT	MEANING
FPO: [N1,N2] TrapFrame @ Address	<i>N1</i> is the total number of parameters. <i>N2</i> is the number of DWORD values for the locals. <i>Address</i> is the address of the trap frame.
FPO: TaskGate Segment:0	<i>Segment</i> is the segment selector for the task gate.
FPO: [EBP 0xBase]	<i>Base</i> is the base pointer for the frame.

The **kd** command displays the raw stack data. Each DWORD value is displayed on a separate line. Symbol information is displayed for those lines together with associated symbols. This format creates a more detailed list than the other **k|*** commands. The **kd** command is equivalent to a [dds \(Display Memory\)](#) command that uses the stack address as its parameter.

If you use the **k** command at the beginning of a function (before the function prolog has been executed), you receive incorrect results. The debugger uses the frame register to compute the current backtrace, and this register is not set correctly for a function until its prolog has been executed.

In user mode, the stack trace is based on the stack of the current thread. For more information about threads, see [Controlling Processes and Threads](#).

In kernel mode, the stack trace is based on the current [register context](#). You can set the register context to match a specific thread, context record, or trap frame.

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

[Send comments about this topic to Microsoft](#)

|+, |- (Set Source Options)

5/31/2017 • 1 min to read • [Edit Online](#)

The **|+** and **|-** commands set the source line options that control source display and program stepping options.

```
l+option  
l-Option  
l{+|-}
```

Parameters

+ or **-**

Specifies whether a given option is to be turned on (plus sign [+]) or turned off (minus sign [-]).

Option

One of the following options. The options must be in lowercase letters.

|

Displays source line numbers at the command prompt. You can disable source line display through **|-ls** or **.prompt_allow -src**. To make the source line numbers visible, you must enable source line display through both mechanisms.

o

Hides all messages (other than the source line and line number) when you are stepping through code. (The **s** option must also be active for the **o** option to have any effect.)

s

Displays source lines and source line numbers at the command prompt.

t

Starts [source mode](#). If this mode is not set, the debugger is in [assembly mode](#).

Turns on or turns off all options.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about source debugging and related commands, see [Debugging in Source Mode](#). For more information about assembly debugging and related commands, see [Debugging in Assembly Mode](#).

Remarks

If you omit *Option*, the previously set options are displayed. In this case, the **|+** and **|-** commands have identical

effects. However, you must include a plus sign (+) or minus sign (-) for the **I** command to work.

You can include only one *Option* every time that you issue this command. If you list more than one option, only the first option is detected. However, by repeatedly issuing this command, you can turn on or off as many options as you want. (In other words, **I+Ist** does not work, but **I+I; I+s; I+t** does achieve the effect that you want.)

When you specify the **s** option, source lines and line numbers are displayed when you step through code, regardless of whether you specified the **I** option. The **o** option has no effect unless you specify the **s** option.

Source line options do not take effect unless you enable line number loading by using the [.lines \(Toggle Source Line Support\) command](#) or the [-lines command-line option](#). By default, if you have not used these commands, WinDbg turns on source line support and CDB turns it off.

[Send comments about this topic to Microsoft](#)

!ld (Load Symbols)

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ld** command loads symbols for the specified module and updates all module information.

```
!ld ModuleName [/f FileName]
```

Parameters

ModuleName

Specifies the name of the module whose symbols are to be loaded. *ModuleName* can contain a variety of wildcard characters and specifiers.

/f *FileName*

Changes the name selected for the match. By default the module name is matched, but when **/f** is used the file name is matched instead of the module name. *FileName* can contain a variety of wildcard characters and specifiers. For more information on the syntax of wildcard characters and specifiers, see [String Wildcard Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The debugger's default behavior is to use *lazy symbol loading* (also known as [deferred symbol loading](#)). This means that symbols are not actually loaded until they are needed.

The **!ld** command, on the other hand, forces all symbols for the specified module to be loaded.

Additional Information

For more information about deferred (lazy) symbol loading, see [Deferred Symbol Loading](#). For more information about other symbol options, see [Setting Symbol Options](#).

[Send comments about this topic to Microsoft](#)

!m (List Loaded Modules)

5/31/2017 • 4 min to read • [Edit Online](#)

The **!m** command displays the specified loaded modules. The output includes the status and the path of the module.

```
!mOptions [a Address] [m Pattern | M Pattern]
```

Parameters

Options

Any combination of the following options:

D

Displays output using [Debugger Markup Language](#).

O

Displays only loaded modules.

I

Displays only modules whose symbol information has been loaded.

V

Causes the display to be verbose. The display includes the symbol file name, the image file name, checksum information, version information, date stamps, time stamps, and information about whether the module is managed code (CLR). This information is not displayed if the relevant headers are missing or paged out.

U

(Kernel mode only) Displays only user-mode symbol information.

K

(Kernel mode only) Displays only kernel-mode symbol information.

E

Displays only modules that have a symbol problem. These symbols include modules that have no symbols and modules whose symbol status is C, T, #, M, or Export. For more information about these notations, see [Symbol Status Abbreviations](#).

C

Displays checksum data.

1M

Reduces the output so that nothing is included except the names of the modules. This option is useful if you are using the [.foreach](#) token to pipe the command output into another command's input.

SM

Sorts the display by module name instead of by the start address.

In addition, you can include only one of the following options. If you do not include any of these options, the display includes the symbol file name.

I

Displays the image file name.

f

Displays the full image path. (This path always matches the path that is displayed in the initial load notification, unless you issued a [.reload -s](#) command.) When you use f, symbol type information is not displayed.

n

Displays the image name. When you use n, symbol type information is not displayed.

p

Displays the mapped image name. When you use p, symbol type information is not displayed.

t

Displays the file time stamps. When you use t, symbol type information is not displayed.

a *Address*

Specifies an address that is contained in this module. Only the module that contains this address is displayed. If Address contains an expression, it must be enclosed in parentheses.

m *Pattern*

Specifies a pattern that the module name must match. Pattern can contain a variety of wildcard characters and specifiers. For more information about the syntax of this information, see [String Wildcard Syntax](#).

Note In most cases, the module name is the file name without the file name extension. For example, if you want to display information about the Flpydisk.sys driver, use the lm mflpydisk command, not lm mflpydisk.sys. In some cases, the module name differs significantly from the file name.

M *Pattern*

Specifies a pattern that the image path must match. Pattern can contain a variety of wildcard characters and specifiers. For more information about the syntax of this information, see [String Wildcard Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **lm** command lists all of the modules and the status of symbols for each module.

Microsoft Windows Server 2003 and later versions of Windows maintain an unloaded module list for user-mode processes. When you are debugging a user-mode process or dump file, the **lm** command also shows these unloaded modules.

This command shows several columns or fields, each with a different title. Some of these titles have specific meanings:

- *module name* is typically the file name without the file name extension. In some cases, the module name differs significantly from the file name.
- The symbol type immediately follows the module name. This column is not labeled. For more information about the various status values, see [Symbol Status Abbreviations](#). If you have loaded symbols, the symbol file name follows this column.
- The first address in the module is shown as start. The first address after the end of the module is shown

as end. For example, if start is "faab4000" and end is "faab8000", the module extends from 0xFAAB4000 to 0xFAAB7FFF, inclusive.

- **lmv** only: The image path column shows the name of the executable file, including the file name extension. Typically, the full path is included in user mode but not in kernel mode.
- **lmv** only: The loaded symbol image file value is the same as the image name, unless Microsoft CodeView symbols are present.
- **lmv** only: The mapped memory image file value is typically not used. If the debugger is mapping an image file (for example, during minidump debugging), this value is the name of the mapped image.

The following code example shows the **lm** command with a Windows Server 2003 target computer. This example includes the **m** and **s*** options, so only modules that begin with "s" are displayed.

```
kd> lm m s*
start   end     module name
f9f73000 f9f7fd80  sysaudio    (deferred)
fa04b000 fa09b400  srv        (deferred)
faab7000 faac8500  sr         (deferred)
facac000 facbae00  serial     (deferred)
fb008000 fb00ba80  serenum    e:\mysymbols\SereEnum.pdb\.....
fb24f000 fb250000  swenum     (deferred)

Unloaded modules:
f9f53000 f9f61000  swmidi.sys
fb0ae000 fb0b0000  splitter.sys
fb040000 fb043000  Sfloppy.SYS
```

Examples

The following two examples show the **lm** command once without any options and once with the **sm** option. Compare the sort order in the two examples.

Example 1:

```
0:000> lm
start   end     module name
01000000 0100d000  stst      (deferred)
77c10000 77c68000  msvcrt    (deferred)
77dd0000 77e6b000  ADVAPI32  (deferred)
77e70000 77f01000  RPCRT4   (deferred)
7c800000 7c8f4000  kernel32  (deferred)
7c900000 7c9b0000  ntdll     (private pdb symbols) c:\db20sym\ntdll.pdb
```

Example 2:

```
0:000> lmsm
start   end     module name
77dd0000 77e6b000  ADVAPI32  (deferred)
7c800000 7c8f4000  kernel32  (deferred)
77c10000 77c68000  msvcrt    (deferred)
7c900000 7c9b0000  ntdll     (private pdb symbols) c:\db20sym\ntdll.pdb
77e70000 77f01000  RPCRT4   (deferred)
01000000 0100d000  stst      (deferred)
```

[Send comments about this topic to Microsoft](#)

In (List Nearest Symbols)

5/31/2017 • 1 min to read • [Edit Online](#)

The **In** command displays the symbols at or near the given address.

```
In Address
In /D Address
```

Parameters

Address

Specifies the address where the debugger should start to search for symbols. The nearest symbols, either before or after *Address*, are displayed. For more information about the syntax, see [Address and Address Range Syntax](#).

/D

Specifies that the output is displayed using [Debugger Markup Language \(DML\)](#). The DML output includes a link that you can use to explore the module that contains the nearest symbol. It also includes a link that you can use to set a breakpoint.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

You can use the **In** command to help determine what a pointer is pointing to. This command can also be useful when you are looking at a corrupted stack to determine which procedure made a call.

If source line information is available, the **In** display also includes the source file name and line number information.

If you are using a [source server](#), the **In** command displays information that is related to the source server.

[Send comments about this topic to Microsoft](#)

Is, Isa (List Source Lines)

5/31/2017 • 1 min to read • [Edit Online](#)

The **Is** and **Isa** commands display a series of lines from the current source file and advance the current source line number.

```
ls [.] [first] [, count]
lsa [.] address [, first [, count]]
```

Parameters

- Causes the command to look for the source file that the debugger engine or the [.srcpath \(Set Source Path\)](#) command are using. If the period (.) is not included, **Is** uses the file that was most recently loaded with the [!sf \(Load Source File\)](#) command.

address

Specifies the address where the source display is to begin.

For more information about the syntax, see [Address and Address Range Syntax](#).

first

Specifies the first line to display. The default value is the current line.

count

Specifies the quantity of lines to display. The default value is 20 (0x14), unless you have changed the default value by using the [!sp -a](#) command.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

After you run the **Is** or **Isa** command, the current line is redefined as the final line that is displayed plus one. The current line is used in future **Is**, **Isa**, and **Isc** commands.

See also

[Isc \(List Current Source\)](#)

[!sf, !sf- \(Load or Unload Source File\)](#)

[Send comments about this topic to Microsoft](#)

lsc (List Current Source)

5/31/2017 • 1 min to read • [Edit Online](#)

The **lsc** command displays the current source file name and line number.

```
lsc
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

See also

[ls, lsa \(List Source Lines\)](#)

[lsf, lsf- \(Load or Unload Source File\)](#)

[Send comments about this topic to Microsoft](#)

Ise (Launch Source Editor)

5/31/2017 • 1 min to read • [Edit Online](#)

The **Ise** command opens an editor for the current source file.

```
Ise
```

Environment

Modes	User-mode, kernel-mode
Targets	Live, crash dump
Platforms	All

Remarks

The **Ise** command opens an editor for the current source file. This command is equivalent to clicking **Edit this file** in the shortcut menu of the [Source window](#) in WinDbg.

The editor is opened on the computer that the target is running on, so you cannot use the **Ise** command from a remote client.

The WinDiff editor registry information or the value of the WINDBG_INVOKE_EDITOR environment variable determine which editor is opened. For example, consider the following value of WINDBG_INVOKE_EDITOR.

```
c:\my\path\myeditor.exe -file %f -line %l
```

This value indicates that Myeditor.exe opens to the one-based line number of the current source file. The **%l** option indicates that line numbers should be read as one-based, and **%f** indicates that the current source file should be used. You could also include **%L** to indicate that line numbers are zero-based or **%p** to indicate that the current source file should be used.

[Send comments about this topic to Microsoft](#)

!sf, !sf- (Load or Unload Source File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **!sf** and **!sf-** commands load or unload a source file.

```
!sf Filename  
!sf- Filename
```

Parameters

Filename

Specifies the file to load or unload. If this file is not located in the directory where the debugger was opened from, you must include an absolute or relative path. The file name must follow Microsoft Windows file name conventions.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **!sf** command loads a source file.

The **!sf-** command unloads a source file. You can use this command to unload files that you previously loaded with **!sf** or automatically loaded source files. You cannot use **!sf-** to unload files that were loaded through WinDbg's [File | Open Source File](#) command or files that a WinDbg workspace loaded.

In CDB or KD, you can view source files in the [Debugger Command window](#). In WinDbg, source files are loaded as new [Source windows](#).

For more information about source files, source paths, and other ways to load source files, see [Source Path](#).

See also

[!s, !sa \(List Source Lines\)](#)

[!sc \(List Current Source\)](#)

[Send comments about this topic to Microsoft](#)

Lsp (Set Number of Source Lines)

5/31/2017 • 1 min to read • [Edit Online](#)

The **Lsp** command controls how many source lines are displayed while you step through or execute code or use the [Is and Isa commands](#).

```
lsp [-a] LeadingLines TrailingLines
lsp [-a] TotalLines
lsp [-a]
```

Parameters

-a

Sets or displays the number of lines that **Is** and **Isa** show. If you omit **-a**, **Lsp** sets or displays the number of lines that are shown while you step through and execute code.

LeadingLines

Specifies the number of lines to show before the current line.

TrailingLines

Specifies the number of lines to show after the current line.

TotalLines

Specifies the total number of lines to show. This number is divided evenly between leading and trailing lines. (If this number is odd, more trailing lines are displayed.)

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

When you use the **Lsp** command together with no parameters, **Lsp** displays the current leading line and trailing line values that you used while stepping. When you use this command together with only the **-a** parameter, **Lsp** displays the values that you used while stepping and for the [Is and Isa commands](#).

When you step through a program or break in after program execution, the previous **Lsp** command determines the number of leading and trailing lines that are displayed. When you use **Isa**, the previous **Lsp -a** command determines the number of leading and trailing lines that are displayed. When you use **Is**, all lines appear as a single block, so the previous **Lsp -a** command determines the total number of lines that are displayed.

Additional Information

For more information about source debugging and related commands, see [Debugging in Source Mode](#).

[Send comments about this topic to Microsoft](#)

m (Move Memory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **m** command copies the contents of memory from one location to another.

Do not confuse this command with the [~m \(Resume Thread\)](#) command.

```
m Range Address
```

Parameters

Range

Specifies the memory area to copy. For more information about the syntax of this parameter, see [Address and Address Range Syntax](#).

Address

Specifies the starting address of the destination memory area. For more information about the syntax of this parameter, see [Address and Address Range Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

The memory area that *Address* specifies can be part of the memory area that *Range* specifies. Overlapping moves are handled correctly.

[Send comments about this topic to Microsoft](#)

n (Set Number Base)

5/31/2017 • 1 min to read • [Edit Online](#)

The **n** command sets the default number base (radix) to the specified value or displays the current number base.

Do not confuse this command with the [~n \(Suspend Thread\)](#) command.

```
n [Radix]
```

Parameters

Radix

Specifies the default number base that is used for numeric display and entry. You can use one of the following values.

VALUE	DESCRIPTION
8	Octal
10	Decimal
16	Hexadecimal

If you omit *Radix*, the current default number base is displayed.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The current radix affects the input and output of MASM expressions. It does not affect the input or output of C++ expressions. For more information about these expressions, see [Evaluating Expressions](#).

The default radix is set to 16 when the debugger is started.

In all MASM expressions, numeric values are interpreted as numbers in the current radix (16, 10, or 8). You can override the default radix by specifying the **0x** prefix (hexadecimal), the **0n** prefix (decimal), the **0t** prefix (octal), or the **0y** prefix (binary).

[Send comments about this topic to Microsoft](#)

ob, ow, od (Output to Port)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ob**, **ow**, and **od** commands send a byte, word, or double word to the selected port.

```
ob Address Value
ow Address Value
od Address Value
```

Parameters

Address

Specifies the address of the port.

Value

Specifies the hexadecimal value to write to the port.

Environment

Modes	Kernel mode only
Targets	Live debugging only
Platforms	x86-based only

Remarks

The **ob** command writes a single byte, the **ow** command writes a word, and the **od** command writes a double word.

Make sure that you do not send a word or a double-word to a port that does not support this size.

See also

[ib, id, iw \(Input from Port\)](#)

[Send comments about this topic to Microsoft](#)

p (Step)

5/31/2017 • 2 min to read • [Edit Online](#)

The **p** command executes a single instruction or source line and optionally displays the resulting values of all registers and flags. When subroutine calls or interrupts occur, they are treated as a single step.

User-Mode

```
[~Thread] p[r] [= StartAddress] [Count] ["Command"]
```

Kernel-Mode

```
p[r] [= StartAddress] [Count] ["Command"]
```

Parameters

Thread

Specifies the threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **pr**, **tr**, or **.prompt_allow -reg** commands. All three of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other three commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where execution should begin. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of instructions or source lines to step through before stopping. Each step is displayed as a separate action in the [Debugger Command window](#). The default value is one.

Command

Specifies a debugger command to execute after the step is performed. This command is executed before the standard **p** results are displayed. If you also use *Count*, the specified command is executed after all stepping is complete (but before the results from the final step are displayed).

Environment

Modes	User mode, kernel mode
Targets	Live debugging only

Additional Information

For more information about issuing the **p** command and an overview of related commands, see [Controlling the Target](#).

Remarks

When you specify *Count*, each instruction is displayed as it is stepped through.

If the debugger encounters a **call** instruction or interrupt while stepping, the called subroutine will execute completely unless a breakpoint is encountered. Control is returned to the debugger at the next instruction after the call or interrupt.

Each step executes a single assembly instruction or a single source line, depending on whether the debugger is in assembly mode or source mode. Use the **I+t** and **I-t** commands or the buttons on the WinDbg toolbar to switch between these modes.

When you are quickly stepping many times in WinDbg, the debugging information windows are updated after each step. If this update causes slower response time, use [.suspend_ui \(Suspend WinDbg Interface\)](#) to temporarily suspend the refreshing of these windows.

[Send comments about this topic to Microsoft](#)

pa (Step to Address)

5/31/2017 • 2 min to read • [Edit Online](#)

The **pa** command executes the program until the specified address is reached, displaying each step.

User-Mode

```
[~Thread] pa [r] [= StartAddress] StopAddress ["Command"]
```

Kernel-Mode

```
pa [r] [= StartAddress] StopAddress ["Command"]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **par**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other three commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. Otherwise, the debugger begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

StopAddress

Specifies the address where execution will stop. This address must match the exact address of an instruction.

Command

Specifies a debugger command to execute after the step is performed. This command is executed before the standard **pa** results are displayed. If you also use **StopAddress**, the specified command is executed after **StopAddress** is reached (but before the results from the final step are displayed).

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **pa** command causes the target to begin executing. This execution continues until the specified instruction is reached or a breakpoint is encountered.

Note If you use this command in kernel mode, execution stops when an instruction is encountered at the specified virtual address in any virtual address space.

During this execution, all steps are displayed explicitly. Called functions are treated as a single unit. Therefore, the display of this command is similar to what you see if you execute **p (Step)** repeatedly until the program counter reaches the specified address.

For example, the following command explicitly steps through the target code until the return address of the current function is reached.

```
0:000> pa @$ra
```

The following example demonstrates using the **pa** command along with the **kb** command to display the stack trace:

```
0:000> pa 70b5d2f1 "kb"
```

[Send comments about this topic to Microsoft](#)

pc (Step to Next Call)

5/31/2017 • 1 min to read • [Edit Online](#)

The **pc** command executes the program until a call instruction is reached.

User-Mode

```
[~Thread] pc [r] [= StartAddress] [Count]
```

Kernel-Mode

```
pc [r] [= StartAddress] [Count]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **pcr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other three commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. Otherwise, the debugger begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of **call** instructions that the debugger must encounter for this command to stop. The default value is one.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **pc** command causes the target to begin executing. This execution continues until a **call** instruction is reached or a breakpoint is encountered.

If the program counter is already on a **call** instruction, the entire call is executed. After this call is returned, execution continues until another **call** is reached. This execution, rather than tracing, of the call is the only difference between **pc** and **tc (Trace to Next Call)**.

In source mode, you can associate one source line with multiple assembly instructions. The **pc** command does not stop at a **call** instruction that is associated with the current source line.

[Send comments about this topic to Microsoft](#)

pct (Step to Next Call or Return)

5/31/2017 • 1 min to read • [Edit Online](#)

The **pct** command executes the program until it reaches a call instruction or a return instruction.

User-Mode

```
[~Thread] pct [r] [= StartAddress] [Count]
```

Kernel-Mode

```
pct [r] [= StartAddress] [Count]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display through the **pctr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other three commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. Otherwise, the debugger begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of **call** or **return** instructions that must be encountered for this command to stop. The default value is one.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **pct** command causes the target to begin executing. This execution continues until a call or **return** instruction is reached or a breakpoint is encountered.

If the program counter is already on a **call** or **return** instruction, the entire call or return is executed. After this call or return is returned, execution continues until another **call** or **return** is reached. This execution, rather than tracing, of the call is the only difference between **pct** and **tct (Trace to Next Call or Return)**.

In source mode, you can associate one source line with multiple assembly instructions. The **pct** command does not stop at a **call** or **return** instruction that is associated with the current source line.

[Send comments about this topic to Microsoft](#)

ph (Step to Next Branching Instruction)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ph** command executes the program until any kind of branching instruction is reached, including conditional or unconditional branches, calls, returns, and system calls.

User-Mode

```
[~Thread] ph [r] [= StartAddress] [Count]
```

Kernel-Mode

```
ph [r] [= StartAddress] [Count]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **phr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other three commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. Otherwise, the debugger begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of branching instructions that must be encountered for this command to stop. The default value is one.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **ph** command causes the target to begin executing. This execution continues until a branching instruction is reached or a breakpoint is encountered.

If the program counter is already on a branching instruction, the entire branching instruction is executed. After this branching instruction is returned, execution continues until another branching instruction is reached. This execution, rather than tracing, of the call is the only difference between **ph** and **th (Trace to Next Branching Instruction)**.

In source mode, you can associate one source line with multiple assembly instructions. The **ph** command does not stop at a branching instruction that is associated with the current source line.

[Send comments about this topic to Microsoft](#)

pt (Step to Next Return)

5/31/2017 • 2 min to read • [Edit Online](#)

The **pt** command executes the program until a return instruction is reached.

User-Mode

```
[~Thread] pt [r] [= StartAddress] [Count] ["Command"]
```

Kernel-Mode

```
pt [r] [= StartAddress] [Count] ["Command"]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **ptr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other three commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. Otherwise, the debugger begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of **return** instructions that must be encountered for this command to stop. The default value is one.

Command

Specifies a debugger command to execute after the step is performed. This command is executed before the standard **pt** results are displayed. If you also use *Count*, the specified command is executed after all stepping is complete (but before the results from the final step are displayed).

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **pt** command causes the target to begin executing. This execution continues until a **return** instruction is reached or a breakpoint is encountered.

If the program counter is already on a **return** instruction, the entire return is executed. After this return is returned, execution continues until another **return** is reached. This execution, rather than tracing, of the call is the only difference between **pt** and [tt \(Trace to Next Return\)](#).

In source mode, you can associate one source line with multiple assembly instructions. The **pt** command does not stop at a **return** instruction that is associated with the current source line.

The following example demonstrates using the **pt** command along with the **kb** command to display the stack trace:

```
0:000> pt "kb"
```

[Send comments about this topic to Microsoft](#)

q, qq (Quit)

5/31/2017 • 1 min to read • [Edit Online](#)

The **q** and **qq** commands end the debugging session. (In CDB and KD, this command also exits the debugger itself. In WinDbg, this command returns the debugger to dormant mode.)

```
q
qq
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

In user-mode debugging, the **q** command ends the debugging session and closes the target application.

In kernel-mode debugging, the **q** command saves the log file and ends the debugging session. The target computer remains locked.

If this command does not work in KD, press **CTRL+R+ENTER** on the debugger keyboard, and then retry the **q** command. If this action does not work, you must use **CTRL+B+ENTER** to exit the debugger.

The **qq** command behaves exactly like the **q** command, unless you are performing remote debugging. During remote debugging, the **q** command has no effect, but the **qq** command ends the debugging server. For more information about this effect, see [Remote Debugging Through the Debugger](#).

[Send comments about this topic to Microsoft](#)

qd (Quit and Detach)

5/31/2017 • 1 min to read • [Edit Online](#)

The **qd** command ends the debugging session and leaves any user-mode target application running. (In CDB and KD, this command also exits the debugger itself. In WinDbg, this command returns the debugger to dormant mode.)

```
qd
```

Environment

Modes	User mode only
Targets	Live debugging only
Platforms	All

Remarks

The **qd** command detaches from a target application and ends the debugging session, leaving the target still running. However, this command is supported only on Microsoft Windows XP and later versions of Windows. On Windows 2000, **qd** generates a warning message and has no effect.

When you are performing remote debugging through the debugger, you cannot use the **qd** command from a debugging client.

[Send comments about this topic to Microsoft](#)

r (Registers)

5/31/2017 • 6 min to read • [Edit Online](#)

The **r** command displays or modifies registers, floating-point registers, flags, pseudo-registers, and fixed-name aliases.

User-Mode

```
[~Thread] r[M Mask|F|X|?] [ Register[:[Num]Type] [= [Value]] ]  
r.
```

Kernel-Mode

```
[Processor] r[M Mask|F|X|Y|YI|?] [ Register[:[Num]Type] [= [Value]] ]  
r.
```

Parameters

Processor

Specifies the processor that the registers are read from. The default value is zero. If you specify *Processor*, you cannot include the *Register* parameter--all registers are displayed. For more information about the syntax, see [Multiprocessor Syntax](#). You can specify processors only in kernel mode.

Thread

Specifies the thread that the registers are read from. If you do not specify a thread, the current thread is used. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

M Mask

Specifies the mask to use when the debugger displays the registers. The "M" must be an uppercase letter. *Mask* is a sum of bits that indicate something about the register display. The meaning of the bits depends on the processor and the mode (see the tables in the following Remarks section for more information). If you omit **M**, the default mask is used. You can set or display the default mask by using the [Rm \(Register Mask\)](#) command.

F

Displays the floating-point registers. The "F" must be an uppercase letter. This option is equivalent to **M 0x4**.

X

Displays the SSE XMM registers. This option is equivalent to **M 0x40**.

Y

Displays the AVX YMM registers. This option is equivalent to **M 0x200**.

YI

Displays the AVX YMM integer registers. This option is equivalent to **M 0x400**.

?

(Pseudo-register assignment only) Causes the pseudo-register to acquire typed information. Any type is permitted. For more information about the **r?** syntax, see [Debugger Command Program Examples](#).

Register

Specifies the register, flag, pseudo-register, or fixed-name alias to display or modify. You must not precede

this parameter with at (@) sign. For more information about the syntax, see [Register Syntax](#).

Num

Specifies the number of elements to display. If you omit this parameter but you include *Type*, the full register length is displayed.

Type

Specifies the data format to display each register element in. You can use *Type* only with 64-bit and 128-bit vector registers. You can specify multiple types.

You can specify one or more of the following values.

TYPE	DISPLAY FORMAT
ib	Signed byte
ub	Unsigned byte
iw	Signed word
uw	Unsigned word
id	Signed DWORD
ud	Unsigned DWORD
iq	Signed quad-word
uq	Unsigned quad-word
f	32-bit floating-point
d	64-bit floating-point

Value

Specifies the value to assign to the register. For more information about the syntax, see [Numerical Expression Syntax](#).

.

Displays the registers used in the current instruction. If no registers are used, no output is displayed.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

Remarks

If you do not specify *Register*, the **r** command displays all the non-floating-point registers, and the **rF** command displays all the floating-point registers. You can change this behavior by using the [rm \(Register Mask\)](#) command.

If you specify *Register* but you omit the equal sign (=) and the *Value* parameter, the command displays the current value of the register.

If you specify *Register* and an equal sign (=) but you omit *Value*, the command displays the current value of the register and prompts for a new value.

If you specify *Register*, the equal sign (=), and *Value*, the command changes the register to contain the value. (If *quiet mode* is active, you can omit the equal sign. You can turn on quiet mode by using the [sq \(Set Quiet Mode\)](#) command. In kernel mode, you can also turn on quiet mode by using the KDQUIET environment variable.)

You can specify multiple registers, separated by commas.

In user mode, the **r** command displays registers that are associated with the current thread. For more information about the threads, see [Controlling Processes and Threads](#).

In kernel mode, the **r** command displays registers that are associated with the current *register context*. You can set the register context to match a specific thread, context record, or trap frame. Only the most important registers for the specified register context are actually displayed, and you cannot change their values. For more information about register context, see [Register Context](#).

When you specify a floating-point register by name, the **F** option is not required. When you specify a single floating-point register, the raw hexadecimal value is displayed in addition to the decimal value.

The following *Mask* bits are supported for an x86-based processor or an x64-based processor.

BIT	VALUE	DESCRIPTION
0 1	0x1 0x2	Displays the basic integer registers. (Setting one or both of these bits has the same effect.)
2	0x4	Displays the floating-point registers.
3	0x8	Displays the segment registers.
4	0x10	Displays the MMX registers.

BIT	VALUE	DESCRIPTION
5	0x20	Displays the debug registers. In kernel mode, setting this bit also displays the CR4 register.
6	0x40	Displays the SSE XMM registers.
7	0x80	(Kernel mode only) Displays the control registers, for example CR0, CR2, CR3 and CR8.
8	0x100	(Kernel mode only) Displays the descriptor and task state registers.
9	0x200	Displays the AVX YMM registers in floating point.
10	0x400	Displays the AVX YMM registers in decimal integers.
11	0x800	Displays the AVX XMM registers in decimal integers.

The following *Mask* bits are supported for an Itanium-based processor.

BIT	VALUE	DESCRIPTION
0 1	0x1 0x2	Displays the basic integer registers. (Setting one or both of these bits has the same effect.)
2	0x4	Displays the floating-point registers.
3	0x8	Displays the high, floating-point registers (f32 to f127).
4	0x10	Displays the user debug registers.
5	0x20	(Kernel mode only) Displays the KSPECIAL_REGISTERS.

The following code examples show **r** commands for an x86-based processor.

In kernel mode, the following command shows the registers for processor 2.

```
1: kd> 2r
```

In user mode, the following command shows the registers for thread 2.

```
0:000> ~2 r
```

In user mode, the following command displays all of the **eax** registers that are associated with all threads (in thread index order).

```
0:000> ~* r eax
```

The following command sets the **eax** register for the current thread to 0x000000FF.

```
0:000> r eax=0x000000FF
```

The following command sets the **st0** register to 1.234e+10 (the **F** is optional).

```
0:000> rF st0=1.234e+10
```

The following command displays the zero flag.

```
0:000> r zf
```

The following command displays the **xmm0** register as 16 unsigned bytes and then displays the full contents of the **xmm1** register in double-precision floating-point format.

```
0:000> r xmm0:16ub, xmm1:d
```

If the current syntax is C++, you must precede registers by an at sign (@). Therefore, you could use the following command to copy the **ebx** register to the **eax** register.

```
0:000> r eax = @ebx
```

The following command displays pseudo-registers in the same way that the **r** command displays registers.

```
0:000> r $teb
```

You can also use the **r** command to create *fixed-name aliases*. These aliases are not registers or pseudo-registers, even though they are associated with the **r** command. For more information about these aliases, see [Using Aliases](#).

Here is an example of the **r.** command on an x86-based processor. The last entry of the call stack precedes the command itself.

```
01004af3 8bec      mov      ebp,esp
0:000> r.
ebp=0006ffc0  esp=0006ff7c
```

Here is an example of the **r.** command on an Itanium-based processor.

```
e0000000`83066cf0      ld8.acq r25 = [r45] e0000000`fffff0b18=??????????????????  
1: kd> r.  
r25=ffffffff`d0000006  r45=e0000000`fffff0b18
```

[Send comments about this topic to Microsoft](#)

rdmsr (Read MSR)

5/31/2017 • 1 min to read • [Edit Online](#)

The **rdmsr** command reads a [Model-Specific Register \(MSR\)](#) value from the specified address.

```
rdmsr Address
```

Parameters

Address

Specifies the address of the MSR.

Environment

Modes	Kernel mode only
Targets	Live debugging only
Platforms	All

Remarks

The **rdmsr** command can display MSR's on x86-based, Itanium-based, and x64-based platforms. The MSR definitions are platform-specific.

See also

[wrmsr \(Write MSR\)](#)

[Send comments about this topic to Microsoft](#)

rm (Register Mask)

5/31/2017 • 2 min to read • [Edit Online](#)

The **rm** command modifies or displays the register display mask. This mask controls how registers are displayed by the **r (Registers)** command.

```
rm
rm ?
rm Mask
```

Parameters

?

Displays a list of possible *Mask* bits.

Mask

Specifies the mask to use when the debugger displays the registers. *Mask* is a sum of bits that indicate something about the register display. The meaning of the bits depends on the processor and the mode. For more information; see the tables in the following Remarks section.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The "m" in the command name must be a lowercase letter.

If you use **rm** with no parameters, the current value is displayed, along with an explanation about its bits.

To display the basic integer registers, you must set bit 0 (0x1) or bit 1 (0x2). By default, 0x1 is set for 32-bit targets and 0x2 is set for 64-bit targets. You cannot set these two bits at the same time--if you try to set both bits, 0x2 overrides 0x1.

You can override the default mask by using the **r (Registers)** command together with the **M** option.

The following *Mask* bits are supported for an x86-based processor or an x64-based processor.

BIT	VALUE	DESCRIPTION
0 1	0x1 0x2	Displays the basic integer registers. (Setting one or both of these bits has the same effect.)

BIT	VALUE	DESCRIPTION
2	0x4	Displays the floating-point registers.
3	0x8	Displays the segment registers.
4	0x10	Displays the MMX registers.
5	0x20	Displays the debug registers. In kernel mode, setting this bit also displays the CR4 register.
6	0x40	Displays the SSE XMM registers.
7	0x80	(Kernel mode only) Displays the control registers, for example CR0, CR2, CR3 and CR8.
8	0x100	(Kernel mode only) Displays the descriptor and task state registers.
9	0x200	Displays the AVX YMM registers in floating point.
10	0x400	Displays the AVX YMM registers in decimal integers.
11	0x800	Displays the AVX XMM registers in decimal integers.

The following *Mask* bits are supported for an Itanium-based processor.

BIT	VALUE	DESCRIPTION
0 1	0x1 0x2	Displays the basic integer registers. (Setting one or both of these bits has the same effect.)
2	0x4	Displays the floating-point registers.
3	0x8	Displays the high, floating-point registers (f32 to f127).

BIT	VALUE	DESCRIPTION
4	0x10	Displays the user debug registers.
5	0x20	(Kernel mode only) Displays the KSPECIAL_REGISTERS.

[Send comments about this topic to Microsoft](#)

s (Search Memory)

5/31/2017 • 6 min to read • [Edit Online](#)

The **s** command searches through memory to find a specific byte pattern.

Do not confuse this command with the [~s \(Change Current Processor\)](#), [~s \(Set Current Thread\)](#), [|s \(Set Current Process\)](#), or [||s \(Set Current System\)](#) commands.

```
s [-[[Flags]Type]] Range Pattern
s -[[Flags]]v Range Object
s -[[Flags]]sa Range
s -[[Flags]]su Range
```

Parameters

[Flags]

Specifies one or more search options. Each flag is a single letter. You must enclose the flags in a single set of brackets ([]). You cannot add spaces between the brackets, except between **n** or **l** and its argument. For example, if you want to specify the **s** and **w** options, use the command **s -[sw]Type Range Pattern**.

You can specify one or more of the following flags:

s

Saves all of the results of the current search. You can use these results to repeat the search later.

r

Restricts the current search to the results from the last saved search. You cannot use the **s** and **r** flags in the same command. When you use **r**, the value of *Range* is ignored, and the debugger searches only those hits that were saved by the previous **s** command.

n Hits

Specifies the number of hits to save when you use the **s** flag. The default value is 1024 hits. If you use **n** together with other flags, **n** must be the last flag, followed by its *Hits* argument. The space between **n** and *Hits* is optional, but you cannot add any other spaces within the brackets. If any later search that uses the **s** flag discovers more than the specified number of hits, the **Overflow error** message is displayed to notify you that not all hits are being saved.

l Length

Causes a search for arbitrary ASCII or Unicode strings to return only strings that are at least *Length* characters long. The default length is 3. This value affects only searches that use the **-sa** or **-su** flags.

w

Searches only writeable memory regions. You must enclose the "w" in brackets.

1

Displays only the addresses of search matches in the search output. This option is useful if you are using the [.foreach](#) token to pipe the command output into another command's input.

Type

Specifies the memory type to search for. Add a hyphen (-) in front of *Type*. You can use one of the following *Type* values.

TYPE	DESCRIPTION
b	Byte (8 bits)
w	WORD (16 bits)
d	DWORD (32 bits)
q	QWORD (64 bits)
a	ASCII string (not necessarily a null-terminated string)
u	Unicode string (not necessarily a null-terminated string)

If you omit *Type*, byte values are used. However, if you use *Flags*, you cannot omit *Type*.

sa

Searches for any memory that contains printable ASCII strings. Use the **I Length** flag to specify a minimum length of such strings. The default minimum length is 3 characters.

su

Searches for any memory that contains printable Unicode strings. Use the **I Length** flag to specify a minimum length of such strings. The default minimum length is 3 characters.

Range

Specifies the memory area to search through. This range cannot be more than 256 MB long unless you use the **L?** syntax. For more information about this syntax, see [Address and Address Range Syntax](#).

Pattern

Specifies one or more values to search for. By default, these values are byte values. You can specify different types of memory in *Type*. If you specify a WORD, DWORD, or QWORD value, enclose it in single quotation marks (for example, **'Tag7'**). If you specify a string, enclose it in double quotation marks (for example, **"This string"**).

-v

Searches for objects of the same type as the specified *Object*.

Object

Specifies the address of an object or the address of a pointer to an object. The debugger then searches for objects of the same type as the object that *Object* specifies.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

If the debugger finds the byte pattern that you specify, the debugger displays the first memory address in the *Range* memory area where the pattern was found. The debugger displays an excerpt of memory that begins at that location in a format that matches the specified *Type* memory type. If *Type* is **a** or **u**, the memory contents and the corresponding ASCII or Unicode characters are displayed.

You must specify the *Pattern* parameter as a series of bytes, unless you specify a different *Type* value. You can enter byte values as numeric or ASCII characters:

- Numeric values are interpreted as numbers in the current radix (16, 10, or 8). To change the default radix, use the **n (Set Number Base)** command. You can override the default radix by specifying the **0x** prefix (hexadecimal), the **0n** prefix (decimal), the **0t** prefix (octal), or the **0y** prefix (binary). **Note** The default radix behaves differently when you use C++ expressions. For more information about these expressions and the radix, see [Evaluating Expressions](#).
- You must enclose ASCII characters in single straight quotation marks. You cannot use C-style escape characters (such as '\0' or '\n').

If you specify multiple bytes, you must separate them by spaces.

The **s-a** and **s-u** commands search for specified ASCII and Unicode strings, respectively. These strings do not have to be null-terminated.

The **s-sa** and **s-su** commands search for unspecified ASCII and Unicode strings. These are useful if you are checking a range of memory to see whether it contains any printable characters. The flags options allow you to specify a minimum length of string to find.

Example: The following command finds ASCII strings that are of length ≥ 3 in the range beginning at 0000000140000000 and ending 400 bytes later.

```
s-sa 0000000140000000 L400
```

The following command finds ASCII strings that are of length ≥ 4 in the range beginning at 0000000140000000 and ending 400 bytes later

```
s -[14]sa 0000000140000000 L400
```

The following command does the same thing, but it limits the search to writeable memory regions.

```
s -[w14]sa 0000000140000000 L400
```

The following command does the same thing, but displays only the address of the match, rather than the address and the value.

```
s -[1w14]sa 0000000140000000 L400
```

The **s-v** command searches for objects of the same data type as the *Object* object. You can use this command only if the desired object is a C++ class or another object that is associated with virtual function tables (Vtables). The **s-v** command searches the *Range* memory area for the addresses of this class's Vtables. If multiple Vtables exist in this class, the search algorithm looks for all of these pointer values, separated by the proper number of bytes. If

any matches are found, the debugger returns the base address of the object and full information about this object--similar to the output of the **dt (Display Type)** command.

Example: Assume the current radix is 16. The following three command all do the same thing: search memory locations 0012FF40 through 0012FF5F for "Hello".

```
0:000> s 0012ff40 L20 'H' 'e' 'l' 'l' 'o'
```

```
0:000> s 0012ff40 L20 48 65 6c 6c 6f
```

```
0:000> s -a 0012ff40 L20 "Hello"
```

These commands locate each appearance of "Hello" and return the address of each such pattern--that is, the address of the letter "H".

The debugger returns only patterns that are completely contained in the search range. Overlapping patterns are found correctly. (In other words, the pattern "QQQ" is found three times in "QQQQQ".)

The following example shows a search that uses the *Type* parameter. This command searches memory locations 0012FF40 through 0012FF5F for the double-word 'VUTS':

```
0:000> s -d 0012ff40 L20 'VUTS'
```

On little-endian computers, 'VUTS' is the same as the byte pattern 'S' 'T' 'U' 'V'. However, searches for WORDs, DWORDs, and QWORDs return only results that are correctly byte-aligned.

[Send comments about this topic to Microsoft](#)

so (Set Kernel Debugging Options)

5/31/2017 • 1 min to read • [Edit Online](#)

The **so** command sets or displays the kernel debugging options.

```
so [Options]
```

Parameters

Options

One or more of the following options:

NOEXTWARNING

Does not issue a warning when the debugger cannot find an extension command.

NOVERSIONCHECK

Does not check the version of debugger extension DLLs.

If you omit *Options*, the current options are displayed.

Environment

Modes	Kernel mode only
Targets	Live, crash dump
Platforms	All

Remarks

You can also set kernel debugging options using the `_NT_DEBUG_OPTIONS` environment variable.

[Send comments about this topic to Microsoft](#)

sq (Set Quiet Mode)

5/31/2017 • 1 min to read • [Edit Online](#)

The **sq** command turns quiet mode on or off.

```
sq
sq{e|d}
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **sqe** command turns quiet mode on, and the **sqd** command turns it off. The **sq** command turns on and off quiet mode. Each of these commands also displays the new quiet mode status.

You can set quiet mode in KD or kernel-mode WinDbg by using the KDQUIET [environment variable](#). (Note that quiet mode exists in both user-mode and kernel-mode debugging, but the KDQUIET environment variable is only recognized in kernel mode.)

Quiet mode has three distinct effects:

- The debugger does not display messages every time that an extension DLL is loaded or unloaded.
- The **r (Registers)** command no longer requires an equal sign (=) in its syntax.
- When you break into a target computer while kernel debugging, the long warning message is suppressed.

Do not confuse quiet mode with the effects of the **-myob command-line option** (in CDB and KD) or the **-Q command-line option** (in WinDbg).

[Send comments about this topic to Microsoft](#)

ss (Set Symbol Suffix)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ss** command sets or displays the current suffix value that is used for symbol matching in numeric expressions.

```
ss [a|w|n]
```

Parameters

a

Specifies that the symbol suffix should be "A", matching many ASCII symbols.

w

Specifies that the symbol suffix should be "W", matching many Unicode symbols.

n

Specifies that the debugger should not use a symbol suffix. (This parameter is the default behavior.)

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about symbol matching, see [Symbol Syntax and Symbol Matching](#).

Remarks

If you specify the **ss** command together with no parameters, the current state of the suffix value is displayed.

[Send comments about this topic to Microsoft](#)

sx, sxd, sxe, sxi, sxn, sxr, sx- (Set Exceptions)

5/31/2017 • 4 min to read • [Edit Online](#)

The **sx**/* commands control the action that the debugger takes when an exception occurs in the application that is being debugged, or when certain events occur.

```
sx

sx{e|d|i|n} [-c "Cmd1"] [-c2 "Cmd2"] [-h] {Exception|Event|*}

sx- [-c "Cmd1"] [-c2 "Cmd2"] {Exception|Event|*}

sxr
```

Parameters

-c "Cmd1"

Specifies a command that is executed if the exception or event occurs. This command is executed when the first chance to handle this exception occurs, regardless of whether this exception breaks into the debugger. You must enclose the *Cmd1* string in quotation marks. This string can include multiple commands, separated by semicolons. The space between the -c and the quoted command string is optional.

-c2"Cmd2"

Specifies a command that is executed if the exception or event occurs and is not handled on the first chance. This command is executed when the second chance to handle this exception occurs, regardless of whether this exception breaks into the debugger. You must enclose the *Cmd2* string in quotation marks. This string can include multiple commands, separated by semicolons. The space between the -c2 and the quoted command string is optional.

-h

Changes the specified event's handling status instead of its break status. If *Event* is **cc**, **hc**, **bpec**, or **ssec**, you do not have to use the **-h** option.

Exception

Specifies the exception number that the command acts on, in the current radix.

Event

Specifies the event that the command acts on. These events are identified by short abbreviations. For a list of the events, see [Controlling Exceptions and Events](#).

Affects all exceptions that are not otherwise explicitly named for **sx**. For a list of explicitly named exceptions, see [Controlling Exceptions and Events](#).

Environment

Modes	User mode, kernel mode
Targets	Live debugging only

Platforms	All
-----------	-----

Additional Information

For more information about break status and handling status, descriptions of all event codes, a list of the default status for all events, and other methods of controlling this status, see [Controlling Exceptions and Events](#).

Remarks

The **sx** command displays the list of exceptions for the current process and the list of all nonexception events and displays the default behavior of the debugger for each exception and event.

The **sxe**, **sxd**, **sxn**, and **sxi** commands control the debugger settings for each exception and event.

The **sxr** command resets all of the exception and event filter states to the default settings. Commands are cleared, break and continue options are reset to their default settings, and so on.

The **sx-** command does not change the handling status or the break status of the specified exception or event. This command can be used if you wish to change the first-chance command or second-chance command associated with a specific event, but do not wish to change anything else.

If you include the **-h** option (or if the **cc**, **hc**, **bpec**, or **ssec** events are specified), the **sxe**, **sxd**, **sxn**, and **sxi** commands control the [handling status](#) of the exception or event. In all other cases, these commands control the [break status](#) of the exception or event.

When you are setting the break status, these commands have the following effects.

COMMAND	STATUS NAME	DESCRIPTION
sxe	Break (Enabled)	When this exception occurs, the target immediately breaks into the debugger before any other error handlers are activated. This kind of handling is called <i>first chance</i> handling.
sxd	Second chance break (Disabled)	The debugger does not break for a first-chance exception of this type (although a message is displayed). If other error handlers do not address this exception, execution stops and the target breaks into the debugger. This kind of handling is called <i>second chance</i> handling.
sxn	Output (Notify)	When this exception occurs, the target application does not break into the debugger at all. However, a message is displayed that notifies the user of this exception.

COMMAND	STATUS NAME	DESCRIPTION
sxi	Ignore	When this exception occurs, the target application does not break into the debugger at all, and no message is displayed.

When you are setting the handling status, these commands have the following effects:

COMMAND	STATUS NAME	DESCRIPTION
sxe	Handled	The event is considered handled when execution resumes.
sxd,sxn,sxi	Not Handled	The event is considered not handled when execution resumes.

You can use the **-h** option together with exceptions, not events. Using this option with **ch**, **bpe**, or **sse** sets the handling status for **hc**, **bpec**, or **ssec**, respectively. If you use the **-h** option with any other event, it has no effect.

Using the **-c** or **-c2** options with **hc**, **bpec**, or **ssec** associates the specified commands with **ch**, **bpe**, or **sse**, respectively.

In the following example, the **sxe** command is used to set the break status of access violation events to break on the first chance, and to set the first-chance command that will be executed at that point to **r eax**. Then the **sx-** command is used to alter the first-chance command to **r ebx**, without changing the handling status. Finally, a portion of the **sx** output is shown, indicating the current settings for access violation events:

```
0:000> sxe -c "r eax" av
0:000> sx- -c "r ebx" av
0:000> sx
av - Access violation - break - not handled
Command: "r ebx"
. . .
```

[Send comments about this topic to Microsoft](#)

t (Trace)

5/31/2017 • 2 min to read • [Edit Online](#)

The **t** command executes a single instruction or source line and optionally displays the resulting values of all registers and flags. When subroutine calls or interrupts occur, each of their steps is also traced.

User-Mode

```
[~Thread] t [r] [= StartAddress] [Count] ["Command"]
```

Kernel-Mode

```
t [r] [= StartAddress] [Count] ["Command"]
```

Parameters

Thread

Specifies threads to thaw. All other threads are frozen. For more information about this syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the [pr](#), [tr](#), or [.prompt_allow -reg](#) commands. All three of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the [l-os](#) command. This setting is separate from the other three commands. To control which registers and flags are displayed, use the [rm \(Register Mask\)](#) command.

StartAddress

Specifies the address where execution should begin. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of instructions or source lines to trace through before stopping. Each step is displayed as a separate action in the [Debugger Command window](#). The default value is one.

Command

Specifies a debugger command to execute after the trace is performed. This command is executed before the standard **t** results are displayed. If you also use *Count*, this command is executed after all tracing is complete (but before the results from the final trace are displayed).

Environment

Modes	User mode, kernel mode
Targets	Live debugging only

Additional Information

For more information about how to issue the **t** command and an overview of related commands, see [Controlling the Target](#).

Remarks

When you specify *Count*, each instruction is displayed as it is stepped through.

Each trace executes a single assembly instruction or a single source line, depending on whether the debugger is in assembly mode or source mode. Use the **I+t** and **I-t** commands or the buttons on the WinDbg toolbar to switch between these modes.

If you want to trace most function calls but skip certain calls, you can use [.step_filter \(Set Step Filter\)](#) to indicate which calls to step over.

You can use the **t** command to trace instructions in ROM.

When you are quickly tracing many times in WinDbg, the debugging information windows are updated after each trace. If this update causes slower response time, use [.suspend_ui \(Suspend WinDbg Interface\)](#) to temporarily suspend the updating of these windows.

[Send comments about this topic to Microsoft](#)

ta (Trace to Address)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ta** command executes the program until the specified address is reached, displaying each step (including steps within called functions).

User-Mode

```
[~Thread] ta [r] [= StartAddress] StopAddress
```

Kernel-Mode

```
ta [r] [= StartAddress] StopAddress
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **tar**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and use of any of them overrides any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other four commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

StopAddress

Specifies the address at which execution stops. This address must match the exact address of an instruction.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **ta** command causes the target to begin executing. This execution continues until the specified instruction is reached or a breakpoint is encountered.

Note If you use the **ta** command in kernel mode, execution stops when an instruction is encountered at the specified virtual address in any virtual address space.

During this execution, all steps are displayed explicitly. If a function is called, the debugger also traces through that function. Therefore, the display of this command resembles what you see if you executed **t (Trace)** repeatedly until the program counter reached the specified address.

For example, the following command explicitly traces through the target code until the return address of the current function is reached.

```
0:000> ta @$ra
```

[Send comments about this topic to Microsoft](#)

tb (Trace to Next Branch)

5/31/2017 • 2 min to read • [Edit Online](#)

The **tb** command executes the program until a branch instruction is reached.

```
tb [r] [= StartAddress] [Count]
```

Parameters

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **tbr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other four commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger starts execution. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of branches to allow. Every time that a branch is encountered, the instruction address and the instruction are displayed. If you omit *Count*, the default number is 1.

Environment

Modes	x86-based: Kernel mode only Itanium-based: User mode, kernel mode x64-based: User mode, kernel mode
Targets	Live debugging only
Platforms	x86-based (GenuineIntel processor family 6 and later), Itanium-based, x64-based

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **tb** command causes the target to begin executing. This execution continues until a branch command is reached.

Execution stops at any branch command that is to be taken. This stopping of execution is always based on the *disassembly* code, even when the debugger is in source mode.

Branch instructions include calls, returns, jumps, counted loops, and while loops. If the debugger encounters an unconditional branch, or a conditional branch for which the condition is true, execution stops. If the debugger

encounters a conditional branch whose condition is false, execution continues.

When execution stops, the address of the branch instruction and any associated symbols are displayed. This information is followed by an arrow and then the address and instructions of the new program counter location.

The **tb** command works only on the current processor. If you use **tb** on a multiprocessor system, execution stops when a branch command is reached or when another processor's event occurs, whichever comes first.

Usually, branch tracing is enabled after the processor control block (PRCB) has been initialized. (The PRCB is initialized early in the boot process.) However, if you have to use the **tb** command before this point, you can use **.force_tb (Forcibly Allow Branch Tracing)** to enable branch tracing earlier. Use the **.force_tb** command cautiously, because it can corrupt your processor state.

[Send comments about this topic to Microsoft](#)

tc (Trace to Next Call)

5/31/2017 • 1 min to read • [Edit Online](#)

The **tc** command executes the program until a call instruction is reached.

User-Mode

```
[~Thread] tc [r] [= StartAddress] [Count]
```

Kernel-Mode

```
tc [r] [= StartAddress] [Count]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **tcr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other four commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of **call** instructions that the debugger must encounter for the **tc** command to end. The default value is one.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **tc** command causes the target to begin executing. This execution continues until the debugger reaches a **call** instruction or encounters a breakpoint.

If the program counter is already on a **call** instruction, the debugger traces into the call and continues executing until it encounters another **call**. This tracing, rather than execution, of the call is the only difference between **tc** and **pc (Step to Next Call)**.

In source mode, you can associate one source line with multiple assembly instructions. This command does not stop at a **call** instruction that is associated with the current source line.

[Send comments about this topic to Microsoft](#)

tct (Trace to Next Call or Return)

5/31/2017 • 1 min to read • [Edit Online](#)

The **tct** command executes the program until it reaches a call instruction or return instruction.

User-Mode

```
[~Thread] tct [r] [= StartAddress] [Count]
```

Kernel-Mode

```
tct [r] [= StartAddress] [Count]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **tctr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-0s** command. This setting is separate from the other four commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of **call** or **return** instructions that the debugger must encounter for the **tct** command to end. The default value is one.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **tct** command causes the target to begin executing. This execution continues until the debugger reaches a **call** or **return** instruction or encounters a breakpoint.

If the program counter is already on a **call** or **return** instruction, the debugger traces into the call or return and continues executing until it encounters another **call** or **return**. This tracing, rather than execution, of the call is the only difference between **tct** and **pct (Step to Next Call or Return)**.

In source mode, you can associate one source line with multiple assembly instructions. This command does not stop at a **call** or **return** instruction that is associated with the current source line.

[Send comments about this topic to Microsoft](#)

th (Trace to Next Branching Instruction)

5/31/2017 • 1 min to read • [Edit Online](#)

The **th** command executes the program until it reaches any kind of branching instruction, including conditional or unconditional branches, calls, returns, and system calls.

User-Mode

```
[~Thread] th [r] [= StartAddress] [Count]
```

Kernel-Mode

```
th [r] [= StartAddress] [Count]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **thr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other four commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of branching instructions that the debugger must encounter for the **th** command to end. The default value is one.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **th** command causes the target to begin executing. Execution continues until the debugger reaches a branching instruction or encounters a breakpoint.

If the program counter is already on a branching instruction, the debugger traces into the branching instruction and continues executing until another branching instruction is reached. This tracing, rather than execution, of the call is the only difference between **th** and **ph (Step to Next Branching Instruction)**.

th is available for all live sessions. This availability is the primary difference between **th** and **tb (Trace to Next Branch)**.

In source mode, you can associate one source line with multiple assembly instructions. This command does not stop at a branching instruction that is associated with the current source line.

[Send comments about this topic to Microsoft](#)

tt (Trace to Next Return)

5/31/2017 • 1 min to read • [Edit Online](#)

The **tt** command executes the program until a return instruction is reached.

User-Mode

```
[~Thread] tt [r] [= StartAddress] [Count]
```

Kernel-Mode

```
tt [r] [= StartAddress] [Count]
```

Parameters

Thread

Specifies threads to continue executing. All other threads are frozen. For more information about the syntax, see [Thread Syntax](#). You can specify threads only in user mode.

r

Turns on and off the display of registers and flags. By default, the registers and flags are displayed. You can disable register display by using the **ttr**, **pr**, **tr**, or **.prompt_allow -reg** commands. All of these commands control the same setting and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other four commands. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

StartAddress

Specifies the address where the debugger begins execution. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

Count

Specifies the number of **return** instructions that the debugger must encounter for the **th** command to end. The default value is one.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands, see [Controlling the Target](#).

Remarks

The **tt** command causes the target to begin executing. This execution continues until the debugger reaches a **return** instruction or encounters a breakpoint

If the program counter is already on a **return** instruction, the debugger traces into the return and continues executing until another **return** is reached. This tracing, rather than execution, of the call is the only difference between **tt** and **pt (Step to Next Return)**.

In source mode, you can associate one source line with multiple assembly instructions. This command does not stop at a **return** instruction that is associated with the current source line.

[Send comments about this topic to Microsoft](#)

u, ub, uu (Unassemble)

5/31/2017 • 1 min to read • [Edit Online](#)

The **u*** commands display an assembly translation of the specified program code in memory.

Do not confuse this command with the [~u \(Unfreeze Thread\)](#) command.

```
u[u|b] Range
u[u|b] Address
u[u|b]
```

Parameters

Range

Specifies the memory range that contains the instructions to disassemble. For more information about the syntax, see [Address and Address Range Syntax](#). If you use the **b** flag, you must specify *Range* by using the "Address **L**Length" syntax, not the "Address1 Address2" syntax.

Address

Specifies the beginning of the memory range to disassemble. Eight instructions (on an x86-based processor) or nine instructions (on an Itanium-based processor) are unassembled. For more information about the syntax, see [Address and Address Range Syntax](#).

b

Determines the memory range to disassemble by counting backward. If **ub** *Address* is used, the disassembled range will be the eight or nine byte range ending with *Address*. If a range is specified using the syntax **ub** *Address* **L***Length*, the disassembled range will be the range of the specified length ending at *Address*.

u

Specifies that the disassembly will continue even if there is a memory read error.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about assembly debugging and related commands, see [Debugging in Assembly Mode](#).

Remarks

If you do not specify a parameter for the **u** command, the disassembly begins at the current address and extends eight instructions (on an x86-based or x64-based processor) or nine instructions (on an Itanium-based processor). When you use **ub** without a parameter, the disassembly includes the eight or nine instructions before the current address.

Do not confuse this command with the [up \(Unassemble from Physical Memory\)](#). The **u** command disassembles only virtual memory, while the **up** command disassembles only physical memory.

[Send comments about this topic to Microsoft](#)

uf (Unassemble Function)

5/31/2017 • 1 min to read • [Edit Online](#)

The **uf** command displays an assembly translation of the specified function in memory.

```
uf [Options] Address
```

Parameters

Options

One or more of the following options:

/c

Displays only the call instructions in a routine instead of the full disassembly. Call instructions can be useful for determination of caller and callee relationships from disassembled code.

/D

Creates linked callee names for navigation of the call graph.

/m

Relaxes the blocking requirements to permit multiple exits.

/o

Sorts the display by address instead of by function offset. This option presents a memory-layout view of a full function.

/O

Creates linked call lines for accessing call information and creating breakpoints.

/i

Displays the number of instructions in a routine.

Address

Specifies the address of the function to disassemble. For more information about the syntax, see [Address and Address Range Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about assembly debugging and related commands, see [Debugging in Assembly Mode](#).

Remarks

The display shows the whole function, according to the function order.

[Send comments about this topic to Microsoft](#)

up (Unassemble from Physical Memory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **up** command displays an assembly translation of the specified program code in physical memory.

```
up Range
up Address
up
```

Parameters

Range

Specifies the memory range in physical memory that contains the instructions to disassemble. For more information about the syntax, see [Address and Address Range Syntax](#).

Address

Specifies the beginning of the memory range in physical memory to disassemble. Eight instructions (on an x86-based processor) or nine instructions (on an Itanium-based processor) are unassembled. For more information about the syntax, see [Address and Address Range Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about assembly debugging and related commands, see [Debugging in Assembly Mode](#).

Remarks

If you do not specify a parameter for the **up** command, the disassembly begins at the current address and extends eight instructions (on an x86-based processor) or nine instructions (on an Itanium-based processor).

Do not confuse this command with the [u \(Unassemble\)](#). The **up** command disassembles only physical memory, while the **u** command disassembles only virtual memory.

[Send comments about this topic to Microsoft](#)

ur (Unassemble Real Mode BIOS)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ur** command displays an assembly translation of the specified 16-bit real-mode code.

```
ur Range
ur Address
ur
```

Parameters

Range

Specifies the memory range that contains the instructions to disassemble. For more information about the syntax, see [Address and Address Range Syntax](#).

Address

Specifies the beginning of the memory range to disassemble. Eight instructions (on an x86-based processor) or nine instructions (on an Itanium-based processor) are unassembled. For more information about the syntax, see [Address and Address Range Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how to debug BIOS code, see [Debugging BIOS Code](#).

Remarks

If you do not specify *Range* or *Address*, the disassembly begins at the current address and extends eight instructions (on an x86-based processor) or nine instructions (on an Itanium-based processor).

If you are examining 16-bit real-mode code on an x86-based processor, both the **ur** command and the **u (Unassemble)** command give correct results.

However, if real-mode code exists in a location where the debugger is not expecting it (for example, a non-x86 computer that is running or emulating x86-based BIOS code from a plug-in card), you must use **ur** to correctly disassemble this code.

If you use **ur** on 32-bit or 64-bit code, the command tries to disassemble the code as if it were 16-bit code. This situation produces meaningless results.

[Send comments about this topic to Microsoft](#)

ux (Unassemble x86 BIOS)

5/31/2017 • 1 min to read • [Edit Online](#)

The **ux** command displays the instruction set of the x86-based BIOS code.

```
ux [Address]
```

Parameters

Address

Specifies the memory offset within the x86-based BIOS code. If you omit this parameter or specify zero, the default offset is the beginning of the BIOS.

Environment

Modes	Kernel mode only
Targets	Live debugging only
Platforms	x86-based only

Additional Information

For more information about how to debug BIOS code, see [Debugging BIOS Code](#).

Remarks

The debugger displays the instructions that are generated from the first eight lines of code, beginning at the *Address* offset.

To make the **ux** command work correctly, HAL symbols must be available to the debugger. If the debugger cannot find these symbols, the debugger displays a "couldn't resolve" error.

[Send comments about this topic to Microsoft](#)

vercommand (Show Debugger Command Line)

5/31/2017 • 1 min to read • [Edit Online](#)

The **vercommand** command displays the command that opened the debugger.

```
vercommand
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

[Send comments about this topic to Microsoft](#)

version (Show Debugger Version)

5/31/2017 • 1 min to read • [Edit Online](#)

The **version** command displays version information about the debugger and all loaded extension DLLs. This command also displays the current version of the operating system of the target computer.

Do not confuse this command with the [!version \(Show DLL Version\)](#) extension command.

```
version
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump

wrmsr (Write MSR)

5/31/2017 • 1 min to read • [Edit Online](#)

The **wrmsr** command writes a value to a Model-Specific Register (MSR) at the specified address.

```
wrmsr Address Value
```

Parameters

Address

Specifies the address of the MSR.

Value

Specifies the 64-bit hexadecimal value to write to the MSR.

Environment

Modes	Kernel mode only
Targets	Live debugging only
Platforms	All

Remarks

The **wrmsr** command can display MSR's on x86-based, Itanium-based, and x64-based platforms. The MSR definitions are platform-specific.

See also

[rdmsr \(Read MSR\)](#)

[Send comments about this topic to Microsoft](#)

wt (Trace and Watch Data)

5/31/2017 • 5 min to read • [Edit Online](#)

The **wt** command runs through the whole function and then displays statistics, when you execute this command at the beginning of a function call.

```
wt [WatchOptions] [= StartAddress] [EndAddress]
```

Parameters

WatchOptions

Specifies how to modify the display. You can use any of the following options.

OPTION	EFFECT
-l Depth	(User mode only) Specifies the maximum depth of the calls to display. Any calls that are at least <i>Depth</i> levels deeper than the starting point are executed silently.
-m Module	(User mode only) Restricts the display to code inside the specified module, plus the first level of calls made from that module. You can include multiple -m options to display code from multiple modules and no other modules.
-i Module	(User mode only) Ignores any code within the specified module. You can include multiple -i options to ignore code from multiple modules. If you use a -m option, the debugger ignores all -i options.
-ni	(User mode only) Does not display any entry into code that is being ignored because of an -m or -i option.
-nc	Does not display individual call information.
-ns	Does not display summary information.
-nw	Does not display warnings during the trace.
-oa	(User mode only) Displays the actual address of call sites.
-or	(User mode only) Displays the return register values of the called function, using the default radix as the base.

OPTION	EFFECT
-oR	(User mode only) Displays the return register values of the called function, in the appropriate type for each return value.

StartAddress

Specifies the address where the debugger begins execution. If you do not use *StartAddress*, execution begins at the instruction that the instruction pointer points to. For more information about the syntax, see [Address and Address Range Syntax](#).

EndAddress

Specifies the address where tracing ends. If you do not use *EndAddress*, a single instruction or function call is executed.

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	User mode: all Kernel mode: x86-based only

Additional Information

For more information about issuing the **wt** command and an overview of related commands, see [Controlling the Target](#).

Remarks

The **wt** command is useful if you want information about the behavior of a specific function, but you do not want to step through the function. Instead, go to the beginning of that function and then issue the **wt** command.

If the program counter is at a point that corresponds to a symbol (such as the beginning of a function or entry point into a module), the **wt** command traces until it reaches the current return address. If the program counter is on a **call** instruction, the **wt** command traces until it returns to the current location. This tracing is profiled in the [Debugger Command window](#) together with output that describes the various calls that the command encounters.

If the **wt** command is issued somewhere other than the beginning of a function, the command behaves like the **p (Step)** command. However, if you specify *EndAddress*, execution continues until that address is reached, even if this execution involves many program steps and function calls.

When you are debugging in source mode, you should trace into the function only to the point where you see the opening bracket of the function body. Then, you can use the **wt** command. (It is typically easier to insert a breakpoint at the first line of the function, or use [Debug | Run to Cursor](#), and then use the **wt** command.)

Because the output from **wt** can be long, you might want to use a log file to record your output.

The following example shows a typical log file.

```

0:000> l+                      Source options set to show source lines
Source options are f:
 1/t - Step/trace by source line
 2/l - List source line for LN and prompt
 4/s - List source code at prompt
 8/o - Only show source code at prompt
0:000> p                      Not yet at the function call: use "p"
> 44:      minorVariableOne = 12;
0:000> p

.....
ntdll!memcpy             24      1     40      19
ntdll!memset             2      29     29      29

```

23 system calls were executed

Calls	System Call
23	ntdll!KiFastSystemCall

In the listing of the trace, the first number specifies the number of instructions that were executed, the second number specifies the number of instructions executed by child processes of the function, and the third number (in brackets) specifies the depth of the function in the stack (taking the initial function as zero). The indentation of the function name shows the call depth.

In the preceding example, **MyModule!myFunction** executes 105 instructions before it calls several subroutines, including **printf** and **fgets**, and then executes 54545 additional instructions after calling those functions, but before issuing a few more calls. However, in the final count, the display shows that **myFunction** executes 112,379 instructions, because this count includes all of the instructions that **myFunction** and its children execute. (The *children* of **myFunction** are functions that are called from **myFunction**, either directly or indirectly.)

In the preceding example, note also that **ILT+1440 (_isatty)** is called 21 times. In the final count, the summary of this function's behavior shows the number of times that it was called, the smallest number of instructions in any single execution, the largest number of instructions in any single execution, and the average number of instructions per execution.

If any system calls are made, they appear in the counter and are listed again at the end of the command output.

[Send comments about this topic to Microsoft](#)

x (Examine Symbols)

5/31/2017 • 6 min to read • [Edit Online](#)

The **x** command displays the symbols in all contexts that match the specified pattern.

```
x [Options] Module!Symbol  
x [Options] *
```

Parameters

Options

Specifies symbol searching options. You can use one or more of the following options:

/0

Displays only the address of each symbol.

/1

Displays only the name of each symbol.

/2

Displays only the address and name of each symbol (not the data type).

/D

Displays the output using [Debugger Markup Language](#).

/t

Displays the data type of each symbol, if the data type is known.

/v

Displays the symbol type (local, global, parameter, function, or unknown) of each symbol. This option also displays the size of each symbol. The size of a function symbol is the size of the function in memory. The size of other symbols is the size of the data type that the symbol represents. Size is always measured in bytes and displayed in hexadecimal format.

/s *Size*

Display only those symbols whose size, in bytes, equals the value of *Size*. The *Size* of a function symbol is the size of the function in memory. The *Size* of other symbols is the size of the data type that the symbol represents. Symbols whose size cannot be determined are always displayed. *Size* must be a nonzero integer.

/q

Displays symbol names in quoted format.

/p

Omits the space before the opening parenthesis when the debugger displays a function name and its arguments. This kind of display can make it easier if you are copying function names and arguments from the **x** display to another location.

/f

Displays the data size of a function.

/d

Displays the data size of data.

/a

Sorts the display by address, in ascending order.

/A

Sorts the display by address, in descending order.

/n

Sorts the display by name, in ascending order.

/N

Sorts the display by name, in descending order.

/z

Sorts the display by size, in ascending order.

/Z

Sorts the display by size, in descending order.

Module

Specifies the module to search. This module can be an .exe, .dll, or .sys file. *Module* can contain a variety of wildcard characters and specifiers. For more information about the syntax, see [String Wildcard Syntax](#).

Symbol

Specifies a pattern that the symbol must contain. *Symbol* can contain a variety of wildcard characters and specifiers. For more information about the syntax, see [String Wildcard Syntax](#).

Because this pattern is matched to a symbol, the match is not case sensitive, and a single leading underscore (_) represents any quantity of leading underscores. You can add spaces within *Symbol*, so that you can specify symbol names that contain spaces (such as "operator new" or "Template<A, B>") without using wildcard characters.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The following command finds all of the symbols in MyModule that contain the string "spin".

```
0:000> x mymodule!*spin*
```

The following command quickly locates the "DownloadMinor" and "DownloadMajor" symbols in MyModule.

```
0:000> x mymodule!downloadm?or
```

You can also show all symbols in the MyModule by using the following command.

```
0:000> x mymodule!*
```

The preceding commands also force the debugger to reload symbol information from MyModule. If you want to reload the symbols in the module with a minimal display, use the following command.

```
0:000> x mymodule!*start*
```

A few symbols always contain the string "start". Therefore, the preceding command always displays some output to verify that the command works. But the preceding command avoids the excessive display length of **x mymodule!***.

The display shows the starting address of each symbol and the full symbol name. If the symbol is a function name, the display also includes a list of its argument types. If the symbol is a global variable, its current value is displayed.

There is one other special case of the **x** command. To display the addresses and names of all local variables for the current context, use the following command.

```
0:000> x *
```

Note In most cases, you cannot access local variables unless private symbols have been loaded. For more information about this situation, see [dbgerr005: Private Symbols Required](#). To display the values of local variables, use the **dv (Display Local Variables)** command.

The following example illustrates the **/0**, **/1**, and **/2** options.

```
0:000:x86> x /0 MyApp!Add*
00b51410
00b513d0

0:000:x86> x /1 MyApp!Add*
MyApp!AddThreeIntegers
MyApp!AddTwoIntegers

0:000:x86> x /2 MyApp!Add*
00b51410      MyApp!AddThreeIntegers
00b513d0      MyApp!AddTwoIntegers
```

The **/0**, **/1**, and **/2** options are useful if you want to use the output of the **x** command as input to the [.foreach](#) command.

```
.foreach ( place { x /0 MyApp!*MySym* } ) { .echo ${place}+0x18 }
```

The following example demonstrates the switch **/f** when used to filter functions on the module notepad.exe.

```
0:000> x /f /v notepad!*main*
prv func  00000001`00003340  249 notepad!WinMain (struct HINSTANCE__ *, struct HINSTANCE__ *, char *, int)
prv func  00000001`0000a7b0  1c notepad!WinMainCRTStartup$filt$0 (void)
prv func  00000001`0000a540  268 notepad!WinMainCRTStartup (void)
```

When you use the **/v** option, the first column of the display shows the symbol type (local, global, parameter, function, or unknown). The second column is the address of the symbol. The third column is the size of the symbol, in bytes. The fourth column shows the module name and symbol name. In some cases, this display is followed by an equal sign (=) and then the data type of the symbol. The source of the symbol (public or full symbol information) is also displayed.

```
kd> x /v nt!CmType*
global 806c9e68 0 nt!CmTypeName = struct _UNICODE_STRING []
global 806c9e68 150 nt!CmTypeName = struct _UNICODE_STRING [42]
global 806c9e68 0 nt!CmTypeName = struct _UNICODE_STRING []
global 805bd7b0 0 nt!CmTypeString = unsigned short *[]
global 805bd7b0 a8 nt!CmTypeString = unsigned short *[42]
```

In the preceding example, the size is given in hexadecimal format, while the data type is given in decimal format. Therefore, in the last line of the preceding example, the data type is an array of 42 pointers to unsigned short integers. The size of this array is $42 \times 4 = 168$, and 168 is displayed in hexadecimal format as 0xA8.

You can use the **/sSize** option to display only those symbols whose size, in bytes, is a certain value. For example, you can restrict the command in the preceding example to symbols that represent objects whose size is 0xA8.

```
kd> x /v /s a8 nt!CmType*
global 805bd7b0 a8 nt!CmTypeString = unsigned short *[42]
```

Working With Data Types

The **/t** option causes the debugger to display information about each symbol's data type. Note that for many symbols, this information is displayed even without the **/t** option. When you use **/t**, such symbols have their data type information displayed twice.

```
0:001> x prymes!__n*
00427d84 myModule!__nullstring = 0x00425de8 "(null)"
0042a3c0 myModule!_nstream = 512
Type information missing error for _nh_malloc
004021c1 myModule!MyStructInstance = struct MyStruct
00427d14 myModule!_NLG_Destination = <no type information>

0:001> x /t prymes!__n*
00427d84 char * myModule!__nullstring = 0x00425de8 "(null)"
0042a3c0 int myModule!_nstream = 512
Type information missing error for _nh_malloc
004021c1 struct MyStruct myModule!MyStructInstance = struct MyStruct
00427d14 <NoType> myModule!_NLG_Destination = <no type information>
```

The **x** command will display an instance of a type.

```
0:001> x foo!MyClassInstance
00f4f354          foo!MyClassInstance = 0x00f78768
```

The **x** command does not display anything based on just the name of a type.

```
0:001> x foo!MyClass
0:001>
```

To display type information using the name of a type, consider using [dt \(Display Type\)](#), it provides information for both types and instances of types:

```
0:001> dt foo!MyClass
+0x000 IntMemberVariable : Int4B
+0x004 FloatMemberVariable : Float
+0x008 BoolMemberVariable : Bool
+0x00c PtrMemberVariable : Ptr32 MyClass
```

Working With Templates

You can use wild cards with the x command to display template classes as shown in this sample.

```
0:001> x Fabric!Common::ConfigEntry*TimeSpan?
000007f6`466a2f9c Fabric!Common::ConfigEntry<Common:: TimeSpan>::ConfigEntry<Common:: TimeSpan> (void)
000007f6`466a3020 Fabric!Common::ConfigEntry<Common:: TimeSpan>::~ConfigEntry<Common:: TimeSpan> (void)
```

Consider using the [dt \(Display Type\)](#) command when working with templates, as the x command does not display individual template class items.

```
0:001> dt foo!Common::ConfigEntry<Common:: TimeSpan>
+0x000 __VFN_table : Ptr64
+0x008 componentConfig_ : Ptr64 Common::ComponentConfig
+0x010 section_      : std::basic_string<wchar_t, std::char_traits<wchar_t>, std::allocator<wchar_t> >
+0x038 key_          : std::basic_string<wchar_t, std::char_traits<wchar_t>, std::allocator<wchar_t> >
```

[Verifying Symbols](#)

[dv \(Display Local Variables\)](#)

[Send comments about this topic to Microsoft](#)

z (Execute While)

5/31/2017 • 2 min to read • [Edit Online](#)

The **z** command executes a command while a given condition is true.

User-Mode

```
Command ; z( Expression )
```

Kernel-Mode

```
Command ; [Processor] z( Expression )
```

Parameters

Command

Specifies the command to execute while the *Expression* condition evaluates to a nonzero value. This command is always executed at least once.

Processor

Specifies the processor that applies to the test. For more information about the syntax, see [Multiprocessor Syntax](#). You can specify processors only in kernel mode.

Expression

Specifies the condition to test. If this condition evaluates to a nonzero value, the *Command* command is executed again and then *Expression* is tested again. For more information about the syntax, see [Numerical Expression Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

In many debugger commands, the semicolon is used to separate unrelated commands. However, in the **z** command, a semicolon separates the "z" from the *Command* parameter.

The *Command* command is always executed at least once, and then *Expression* is tested. If the condition is a nonzero value, the command is again executed, and then *Expression* is tested again. (This behavior is similar to a C-language **do - while** loop, not a simple **while** loop.)

If there are several semicolons to the left of the "z", all commands to the left of the "z" repeat as long as the *Expression* condition is true. Such commands can be any debugger commands that permit a terminal semicolon.

If you add another semicolon and additional commands after the **z** command, these additional commands are executed after the loop is complete. We do not typically recommend a line that begins with "z" because it generates uninteresting output forever unless the condition becomes false because of some other action. Note that you can nest **z** commands.

To break a loop that is continuing for too long, use **CTRL+C** in CDB or KD, or use [Debug | Break](#) or **CTRL+BREAK** in WinDbg.

The following code example shows an unnecessarily complex way to zero the **eax** register.

```
0:000> reax = eax - 1 ; z(eax)
```

The following example increments the **eax** and **ebx** registers until one of them is at least 8 and then it increments the **ecx** register once.

```
0:000> reax=eax+1; rebx=ebx+1; z((eax<8)|(ebx<8)); recx=ecx+1
```

The following example uses C++ expression syntax and uses the pseudo-register **\$t0** as a loop variable.

```
0:000> .expr /s c++
Current expression evaluator: C++ - C++ source expressions
0:000> db pindexcreate[$t0].szKey; r$t0=@t0+1; z( @$t0 < cIndexCreate )
```

Meta-Commands

5/31/2017 • 1 min to read • [Edit Online](#)

This section of the reference discusses the various debugger *meta-commands* that can be used in CDB, KD, and WinDbg. These commands are preceded by a period (.).

[Send comments about this topic to Microsoft](#)

.abandon (Abandon Process)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.abandon** command ends the debugging session, but leaves the target application in a debugging state. This returns the debugger to dormant mode.

```
.abandon [/h]/[n]
```

Parameters

/h

Any outstanding debug event will be continued and marked as handled. This is the default.

/n

Any outstanding debug event will be continued unhandled.

Environment

This command is only supported in Windows XP and later versions of Windows.

Modes	user mode only
Targets	live debugging only
Platforms	all

Additional Information

If the target is left in a debugging state, a new debugger can be attached to it. See [Re-attaching to the Target Application](#) for details. However, after a process has been abandoned once, it can never be restored to a running state without a debugger attached.

[Send comments about this topic to Microsoft](#)

.allow_exec_cmds (Allow Execution Commands)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.allow_exec_cmds** command controls whether execution commands can be used.

```
.allow_exec_cmds 0
.allow_exec_cmds 1
.allow_exec_cmds
```

Parameters

0

Prevents execution commands from being used.

1

Allows execution commands to be used.

Environment

Modes	user mode and kernel mode
Targets	live debugging only
Platforms	all

Additional Information

For a complete list of execution commands, see [Controlling the Target](#).

Remarks

With no parameters, **.allow_exec_cmds** will display whether execution commands are currently permitted.

Execution commands include [g \(Go\)](#), [t \(Trace\)](#), [p \(Step\)](#), and any other command or WinDbg graphical interface action that would cause the target to execute.

[Send comments about this topic to Microsoft](#)

.allow_image_mapping (Allow Image Mapping)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.allow_image_mapping** command controls whether image files will be mapped.

```
.allow_image_mapping [/r] 0
.allow_image_mapping [/r] 1
.allow_image_mapping
```

Parameters

/r

Reloads all modules in the debugger's module list. This is equivalent to [.reload /d](#).

0

Prevents image files from being mapped.

1

Allows image files to be mapped.

Environment

Modes	user mode and kernel mode
Targets	live, crash dump
Platforms	all

Remarks

With no parameters, **.allow_image_mapping** will display whether image file mapping is currently allowed. By default, this mapping is allowed.

Image mapping is most common when a minidump is being debugged. Image mapping can also occur if DbgHelp is unable to access debug records (for example, during kernel debugging when memory has been paged out).

[Send comments about this topic to Microsoft](#)

.apply_dbp (Apply Data Breakpoint to Context)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.apply_dbp** command applies the current process' existing data breakpoints to the specified register context.

```
.apply_dbp [/m Context]
```

Parameters

/m Context

Specifies the address of a register context (CONTEXT structure) in memory to which to apply the current process' data breakpoints.

Environment

Modes	user mode and kernel mode
Targets	live target only
Platforms	all

Additional Information

For more information about breakpoints controlled by the processor, see [Processor Breakpoints \(ba Breakpoints\)](#). For more information about the register context (thread context), see [Register Context](#).

Remarks

Breakpoints that are controlled by the processor are called *data breakpoints* or *processor breakpoints*. These breakpoints are created by the **ba (Break on Access)** command.

These breakpoints are associated with a memory location in the address space of a specific process. The **.apply_dbp** command modifies the specified register context so that these data breakpoints will be active when this context is used.

If the **/m Address** parameter is not used, data breakpoints will be applied to the current register context.

This command can only be used if the target is in native machine mode. For example, if the target is running on a 64-bit machine emulating an x86 processor using [WOW64](#), this command cannot be used.

One example of a time this command is useful is when you are in an exception filter. The **.apply_dbp** command can update the exception filter's stored context. Data breakpoints will then be applied when the exception filter exits and the stored context is resumed. Without such a modification it is possible that data breakpoints would be lost.

[Send comments about this topic to Microsoft](#)

.asm (Change Disassembly Options)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.asm** command controls how disassembly code will be displayed.

```
.asm
.asm[-] Options
```

Parameters

- Causes the specified options to be disabled. If no minus sign is used, the specified options will be enabled.

Options

Can be any number of the following options:

ignore_output_width

Prevents the debugger from checking the width of lines in the disassembly display.

no_code_bytes

(x86 and x64 targets only) Suppresses the display of raw bytes.

source_line

Prefixes each line of disassembly with the line number of the source code.

verbose

(Itanium target only) Causes bundle-type information to be displayed along with the standard disassembly information.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For a description of assembly debugging and related commands, see [Debugging in Assembly Mode](#).

Remarks

Using **.asm** by itself displays the current state of the options.

This command affects the display of any disassembly instructions in the Debugger Command window. In WinDbg it also changes the contents of the Disassembly window.

[Send comments about this topic to Microsoft](#)

.attach (Attach to Process)

5/31/2017 • 2 min to read • [Edit Online](#)

The **.attach** command attaches to a new target application.

```
.attach [-premote RemoteOptions] AttachOptions PID
```

Parameters

RemoteOptions

Specifies a process server to attach to. The options are the same as those for the command line **-premote** option. See [Activating a Smart Client](#) for syntax details.

AttachOptions

Specifies how the attach is to be done. This can include any of the following options:

-b

(Windows XP and later) Prevents the debugger from requesting an initial break-in when attaching to a target process. This can be useful if the application is already suspended, or if you want to avoid creating a break-in thread in the target.

-e

(Windows XP and later) Allows the debugger to attach to a process that is already being debugged. See [Re-attaching to the Target Application](#) for details.

-k

(Windows XP and later) Begins a local kernel debugging session. See [Performing Local Kernel Debugging](#) for details.

-f

Freezes all threads in all target applications, except in the new target being attached to. These threads will remain frozen until an exception occurs in the newly-attached process. Note that an initial breakpoint qualifies as an exception. Individual threads can be unfrozen by using the [~u \(Unfreeze Thread\)](#) command.

-r

(Windows XP and later)

Causes the debugger to start the target process running when it attaches to it. This can be useful if the application is already suspended and you want it to resume execution.

-v

Causes the specified process to be debugged noninvasively.

PID

Specifies the process ID of the new target application.

Environment

Modes	user mode only
--------------	----------------

Targets	live debugging only
Platforms	all

Remarks

This command can be used when CDB is dormant, or if it is already debugging one or more processes. It cannot be used when WinDbg is dormant.

If this command is successful, the debugger will attach to the specified process the next time the debugger issues an execution command. If this command is used several times in a row, execution will have to be requested as many times as this command was used.

Because execution is not permitted during noninvasive debugging, the debugger is not able to noninvasively debug more than one process at a time. This also means that using the **.attach -v** command may render an already-existing invasive debugging session less useful.

Multiple target processes will always be executed together, unless some of their threads are frozen or suspended.

If you wish to attach to a new process and freeze all your existing targets, use the **-f** option. For example, you might be debugging a crash in a client application and want to attach to the server process without letting the client application continue running.

If the **-premote** option is used, the new process will be part of a new system. For details, see [Debugging Multiple Targets](#).

[Send comments about this topic to Microsoft](#)

.beep (Speaker Beep)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.beep** command makes noise on the computer speaker.

```
.beep
```

Environment

This command cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

[Send comments about this topic to Microsoft](#)

.bpcmds (Display Breakpoint Commands)

5/31/2017 • 2 min to read • [Edit Online](#)

The **.bpcmds** command displays the commands that were used to set each of the current breakpoints.

```
.bpcmds
```

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For more information about and examples of how to use breakpoints, other breakpoint commands and methods of controlling breakpoints, see [Using Breakpoints](#).

Remarks

If it is unclear whether a particular breakpoint is set at an address, at a symbolic reference, or at a symbol, use the **.bpcmds** command to shows which breakpoint command was used to create it. The command that was used to create a breakpoint determines its nature:

- The [bp \(Set Breakpoint\)](#) command sets a breakpoint at an address.
- The [bu \(Set Unresolved Breakpoint\)](#) command sets a breakpoint on a symbolic reference.
- The [bm \(Set Symbol Breakpoint\)](#) command sets a breakpoint on symbols that match a specified pattern. If the **/d** switch is included, it creates zero or more breakpoints on addresses (like **bp**), otherwise it creates zero or more breakpoints on symbolic references (like **bu**).
- The [ba \(Break on Access\)](#) command sets a data breakpoint at an address.

The output of **.bpcmds** reflects the current nature of each breakpoint. Each line of the **.bpcmds** display begins with the command used to create it (**bp**, **bu**, or **ba**) followed by the breakpoint ID, and then the location of the breakpoint.

If the breakpoint was created by **ba**, the access type and size are displayed as well.

If the breakpoint was created by **bm** without the **/d** switch, the display indicates the breakpoint type as **bu**, followed by the evaluated symbol enclosed in the **@!"** token (which indicates it is a literal symbol and not a numeric expression or register). If the breakpoint was created by **bm** with the **/d** switch, the display indicates the breakpoint type as **bp**.

Here is an example:

```
0:000> bp notepad!winmain

0:000> .bpcmds
bp0 0x00000001`00003340 ;

0:000> bu myprog!winmain
breakpoint 0 redefined

0:000> .bpcmds
bu0 notepad!winmain;

0:000> bu myprog!LoadFile

0:000> bp myprog!LoadFile+10

0:000> bm myprog!openf*
3: 00421200 @"myprog!openFile"
4: 00427800 @"myprog!openFilter"

0:000> bm /d myprog!closef*
5: 00421600 @"myprog!closeFile"

0:000> ba r2 myprog!LoadFile+2E

0:000> .bpcmds
bu0 notepad!winmain;
bu1 notepad!LoadFile;
bp2 0x0042cc10 ;
bu3 @"myprog!openFile";
bu4 @"myprog!openFilter";
bp5 0x00421600 ;
ba6 r2 0x0042cc2e ;
```

In this example, notice that the output of **.bpcmds** begins with the relevant command ("bu", "bp", or "ba"), followed by the breakpoint number (with no intervening space).

Notice that because breakpoint number 0 was originally set using **bp**, and then was redefined using **bu**, the display shows its type as "bu".

Notice also that breakpoints 3, 4, and 5, which were created by the **bm** commands shown in this example, are displayed as either type "bp" or type "bu", depending on whether the **/d** switch was included when **bm** was used.

[Send comments about this topic to Microsoft](#)

.bpsync (Synchronize Threads at Breakpoint)

5/31/2017 • 1 min to read • [Edit Online](#)

When a thread reaches a breakpoint, the **.bpsync** command freezes all other threads, until the thread to which the breakpoint applies has stepped through the breakpoint.

```
.bpsync 1
.bpsync 0
.bpsync
```

Parameters

1

Causes all threads to freeze when one thread has reached a breakpoint. After the thread to which the breakpoint applies has stepped through the breakpoint, the other threads are unfrozen.

0

Allows other threads to continue executing when one thread has reached a breakpoint. This is the default behavior.

Environment

Modes	user mode only
Targets	live, crash dump
Platforms	all

Remarks

With no parameters, the **.bpsync** command displays the current rule governing breakpoint synchronization behavior.

The **.bpsync** command applies both to software breakpoints (set with **bp**, **bu**, or **bm**) and to processor breakpoints (set with **ba**).

If there is a possibility of multiple threads running through the same code, the **.bpsync 1** command can be useful for capturing all breakpoint occurrences. Without this command, a breakpoint occurrence could be missed because the first thread to reach the breakpoint always causes the debugger to temporarily remove the breakpoint. In the short period when the breakpoint is removed, other threads could reach the same place in the code and not trigger the breakpoint as intended.

The temporary removal of breakpoints is a normal aspect of debugger operation. When the target reaches a breakpoint and is resumed, the debugger has to remove the breakpoint temporarily so that the target can execute the real code. After the real instruction has been executed, the debugger reinserts the break. To do this, the debugger restores the code (or turns off data breaks), does a single-step, and then puts the break back.

Note that if you use **.bpsync 1**, there is a risk of deadlocks among the threads that have been frozen.

[Send comments about this topic to Microsoft](#)

.breakin (Break to the Kernel Debugger)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.breakin** command switches from user-mode debugging to kernel-mode debugging. This command is particularly useful when you are controlling the user-mode debugger from the kernel debugger.

```
.breakin
```

Environment

Modes	user mode only
Targets	live debugging only
Platforms	all

Remarks

If kernel-mode debugging was enabled during the boot process and you are running a user-mode debugger, you can use the **.breakin** command to halt the operating system and transfer control to a kernel debugger.

The **.breakin** command causes a kernel-mode break in the debugger's process context. If a kernel debugger is attached, it will become active. The kernel debugger's [process context](#) will automatically be set to the process of the user-mode debugger, not the user-mode debugger's target process.

This command is primarily useful when debugging a user-mode problem requires retrieving information about the kernel state of the system. Resuming execution in the kernel debugger is necessary before the user-mode debugging session can continue.

When you are [controlling the user-mode debugger from the kernel debugger](#) and the user-mode debugger prompt is visible in the kernel debugger, this command will pause the user-mode debugger and make the kernel-mode debugging prompt appear.

If the system is unable to break into the kernel debugger, an error message is displayed.

This command is also useful if you use the kernel debugger to set a breakpoint in user space and that breakpoint is caught by a user-mode debugger instead of the kernel debugger. Issuing this command in the user-mode debugger will transfer control to the kernel debugger.

If the **.breakin** command is used on a system that was not booted with debugging enabled, it has no effect.

[Send comments about this topic to Microsoft](#)

.browse (Display Command in Browser)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.browse** command displays the output of a specified command in a new [Command Browser window](#).

```
.browse Command
```

Parameters

Command

The command to be executed and displayed in a new Command Browser window.

Remarks

The following example uses the **.browse** command to display the output of the [.chain /D](#) command in a Command Browser window.

```
.browse .chain /D
```

[Send comments about this topic to Microsoft](#)

.bugcheck (Display Bug Check Data)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.bugcheck** command displays the data from a bug check on the target computer.

```
.bugcheck
```

Environment

Modes	kernel mode only
Targets	live, crash dump
Platforms	all

Additional Information

For more information about bug checks, see [Bug Checks \(Blue Screens\)](#). For a description of individual bug checks, see the [Bug Check Code Reference](#) section.

Remarks

This command displays the current bug check data. (This bug check data will be accessible until the crashed machine is rebooted.)

You can also display bug check data on 32-bit systems by using **dd NT!KiBugCheckData L5**, or on 64-bit systems by using **dq NT!KiBugCheckData L5**. However, the **.bugcheck** command is more reliable, because it works in some scenarios that the [d* \(Display Memory\)](#) command will not (such as user-mode minidumps).

The [!analyze](#) extension command is also useful after a bug check occurs.

[Send comments about this topic to Microsoft](#)

.cache (Set Cache Size)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.cache** command sets the size of the cache used to hold data obtained from the target. Also sets a number of cache and memory options.

```
.cache Size  
.cache Option  
.cache
```

Parameters

Size

The size of the kernel debugging cache, in kilobytes. If *Size* is zero, the cache is disabled. The command output displays the cache size in bytes. (The default size is 1000 KB.)

Option

Can be any one of the following options:

hold

Automatic cache flushing is disabled.

unhold

Turns off the **hold** option. (This is the default setting.)

decodeptes

All transition page table entries (PTEs) will be implicitly decoded. (This is the default setting.)

nodecodeptes

Turns off the **decodeptes** option.

forcedecodeptes

All virtual addresses will be translated into physical addresses before access. This option also causes the cache to be disabled. Unless you are concerned with kernel-mode memory, it is more efficient to use **forcedecodeuser** instead.

forcedecodeuser

All user-mode virtual addresses will be translated into physical addresses before access. This option also causes the cache to be disabled.

Note You must activate **forcedecodeuser** (or **forcedecodeptes**) before using [.thread \(Set Register Context\)](#), [.context \(Set User-Mode Address Context\)](#), [.process \(Set Process Context\)](#), or [!session](#) during live debugging. If you use the **/p** option with **.thread** and **.process**, the **forcedecodeuser** option is automatically set. In any other case, you will need to use the **.cache forcedecodeuser** command explicitly.

noforcecodeptes

Turns off the **forcedecodeptes** and **forcedecodeuser** options. (This is the default setting.)

flushall

Deletes the entire virtual memory cache.

flushu

Deletes all entries of ranges with errors from the cache, as well as all user-mode entries.

flush *Address*

Deletes a 4096-byte block of the cache, beginning at *Address*.

Environment

Modes	kernel mode only
Targets	live debugging only
Platforms	all

Remarks

If **.cache** is used with no arguments, the current cache size, status, and options are displayed.

The **.cache forcedecodeuser** or **.cache forcedecodeptes** option will only last as long as the debugger remains broken into the target computer. If any stepping or execution of the target takes place, the **noforce decodeptes** state will again take effect. This prevents the debugger from interfering with execution or a reboot in an unproductive manner.

[Send comments about this topic to Microsoft](#)

.call (Call Function)

5/31/2017 • 4 min to read • [Edit Online](#)

The **.call** command causes the target process to execute a function.

```
.call [/v] Function( Arguments )
.call /s Prototype Function( Arguments )
.call /c
.call /C
```

Parameters

/v

Verbose information about the call and its arguments is displayed.

/s Prototype

Allows you to call the function that is specified by *Function* even though you do not have the correct symbols. In this case, you must have symbols for another function that has the same calling prototype as the function you are trying to call. The *Prototype* parameter is the name of this prototype function.

Function

Specifies the function being called. This can be the name of the function (preferably qualified with a module name), or any other expression that evaluates to the function address. If you need to call a constructor or destructor, you must supply the address -- or else use a C++ expression to evaluate named syntax for the operators (see [Numerical Expression Syntax](#) for details).

Arguments

Specifies the arguments passed to the function. If you are calling a method, the first argument must be **this**, and all other arguments follow it. Arguments should be separated with commas and should match the usual argument syntax. Variable-length argument lists are supported. Expressions within an argument are parsed by the C++ expression evaluator; see [C++ Numbers and Operators](#) for details. You cannot enter a literal string as an argument, but you can use a pointer to a string, or any other memory accessible to the target process.

/c

Clears any existing call on the current thread.

/C

Clears any existing call on the current thread, and resets the context of the current thread to the context stored by the outstanding call.

Environment

Modes	user mode only
Targets	live debugging only
Platforms	x86 and x64 only

Remarks

The specified function is called by the current thread of the current process.

Only the **cdecl**, **stdcall**, **fastcall**, and **thiscall** calling conventions are supported. Managed code cannot be called by this command.

After **.call** is used, the debugger will update the stack, change the instruction pointer to point to the beginning of the called function, and then stop. Use **g (Go)** to resume execution, or **~.g** to execute just the thread making the call.

When the function returns, a break occurs and the debugger displays the return value of the function. The return value is also stored in the **\$callret** pseudo-register, which acquires the type of the return value.

If you have broken into the target using CTRL+C or CTRL+BREAK, the current thread is an additional thread created to handle the breakin. If you issue a **.call** command at this point, the extra thread will be used for the called function.

If you have reached a predefined breakpoint, there is no extra breakin thread. If you use **.call** while at a breakpoint in user mode, you could use **g** to execute the entire process, or **~.g** to execute just the current thread. Using **g** may distort your program's behavior, since you have taken one thread and diverted it to this new function. On the other hand, this thread will still have its locks and other attributes, and thus **~.g** may risk deadlocks.

The safest way to use **.call** is to set a breakpoint in your code at a location where a certain function could be safely called. When that breakpoint is hit, you can use **.call** if you desire that function to run. If you use **.call** at a point where this function could not normally be called, a deadlock or target corruption could result.

It may be useful to add extra functions to your source code that are not called by the existing code, but are intended to be called by the debugger. For example, you could add functions that are used to investigate the current state of your code and its environment and store information about the state in a known memory location. Be sure not to optimize your code, or these functions may be removed by the compiler. Use this technique only as a last resort, because if your application crashes **.call** will not be available when debugging the dump file.

The **.call /c** and **.call /C** commands should only be used if an attempt to use **.call** has failed, or if you changed your mind before entering the **g** command. These should not be used casually, since abandoning an uncompleted call can lead to a corrupted target state.

The following code example shows how the **.call /s** command is used.

```
.call /s KnownFunction UnknownFunction( 1 )
```

In this example, you have private symbols for **KnownFunction**, which takes an integer as its only argument and returns, for example, a pointer to an array. You do not have symbols, or possibly you only have public symbols for **UnknownFunction**, but you do know that it takes an integer as its only argument and returns a pointer to an array. By using the **/s** option, you can specify that **UnknownFunction** will work the same way that **KnownFunction** does. Thus, you can successfully generate a call to **UnknownFunction**.

[Send comments about this topic to Microsoft](#)

.chain (List Debugger Extensions)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.chain** command lists all loaded debugger extensions in their default search order.

```
.chain  
.chain /D
```

Parameters

/D

Displays the output using [Debugger Markup Language](#). In the output, each listed module is a link that you can click to get information about the extensions that are implemented by the module.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For details on loading, unloading, and controlling extensions, see [Loading Debugger Extension DLLs](#). For details on executing extension commands and an explanation of the default search order, see [Using Debugger Extension Commands](#).

[Send comments about this topic to Microsoft](#)

.childdbg (Debug Child Processes)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.childdbg** command controls the debugging of child processes.

```
.childdbg 0
.childdbg 1
.childdbg
```

Parameters

0

Prevents the debugger from debugging child processes.

1

Causes the debugger to debug child processes.

Environment

This command is only supported in Windows XP and later versions of Windows.

Modes	user mode only
Targets	live debugging only
Platforms	x86, x64, and Itanium only

Remarks

Child processes are additional processes launched by the original target application.

With no parameters, **.childdbg** will display the current status of child-process debugging.

[Send comments about this topic to Microsoft](#)

.clients (List Debugging Clients)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.clients** command lists all debugging clients currently connected to the debugging session.

```
.clients
```

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For more details and other commands that can be used while performing remote debugging through the debugger, see [Controlling a Remote Debugging Session](#).

[Send comments about this topic to Microsoft](#)

.closehandle (Close Handle)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.closehandle** command closes a handle owned by the target application.

```
.closehandle Handle
.closehandle -a
```

Parameters

Handle

Specifies the handle to be closed.

-a

Causes all handles owned by the target application to be closed.

Environment

Modes	user mode only
Targets	live debugging only
Platforms	all

Remarks

You can use the **!handle** extension to display the existing handles.

[Send comments about this topic to Microsoft](#)

.cls (Clear Screen)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.cls** command clears the Debugger Command window display.

```
.cls
```

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

[Send comments about this topic to Microsoft](#)

.context (Set User-Mode Address Context)

5/31/2017 • 2 min to read • [Edit Online](#)

The **.context** command specifies which page directory of a process will be used for the user-mode address context, or displays the current user-mode address context.

```
.context [PageDirectoryBase]
```

Parameters

PageDirectoryBase

Specifies the base address for a page directory of a desired process. The user-mode address context will be set to this page directory. If *PageDirectoryBase* is zero, the user-mode address context will be set to the page directory for the current system state. If *PageDirectoryBase* is omitted, the current user-mode address context is displayed.

Environment

Modes	kernel mode only
Targets	live, crash dump
Platforms	all

Additional Information

For more information about the user-mode address context and other context settings, see [Changing Contexts](#).

Remarks

Generally, when you are doing kernel debugging, the only visible user-mode address space is the one associated with the current process.

The **.context** command instructs the kernel debugger to use the specified page directory as the *user-mode address context*. After this command is executed, the debugger will have access to this virtual address space. The page tables for this address space will be used to interpret all user-mode memory addresses. This allows you to read and write to this memory.

The [.process \(Set Process Context\)](#) command has a similar effect. However, the **.context** command sets the user-mode address context to a specific page directory, while the **.process** command sets the *process context* to a specific process. On an x86 processor, these two commands have essentially the same effect. However, on an Itanium processor, a single process may have more than one page directory. In this case, the **.process** command is more powerful, because it will allow access to all the page directories associated with a process. See [Process Context](#) for more details.

If you are doing live debugging, you should issue a [.cache forcedecodeuser](#) command in addition to the **.context** command. This forces the debugger to look up the physical addresses of the memory space needed. (This can be slow, because it often means a huge amount of data must be transferred across the debug cable.)

If you are doing crash dump debugging, the **.cache** command is not needed. However, you will not have access to

any portions of the virtual address space of the user-mode process that were paged to disk when the crash occurred.

Here is an example. Use the **!process** extension to find the directory base for the desired process:

```
kd> !process 0 0
**** NT ACTIVE PROCESS DUMP ****
PROCESS fe5039e0 SessionId: 0 Cid: 0008 Peb: 00000000 ParentCid: 0000
  DirBase: 00030000 ObjectTable: fe529b68 TableSize: 50.
  Image: System

...
PROCESS fe3c0d60 SessionId: 0 Cid: 0208 Peb: 7ffdf000 ParentCid: 00d4
  DirBase: 0011f000 ObjectTable: fe3d0f48 TableSize: 30.
  Image: regsvc.exe
```

Now use the **.context** command with this page directory base.

```
kd> .context 0011f000
```

This enables you to examine the address space in various ways. For example, here is the output of the **!peb** extension:

```
kd> !peb
PEB at 7FFDF000
  InheritedAddressSpace: No
  ReadImageFileExecOptions: No
  BeingDebugged: No
  ImageBaseAddress: 01000000
  Ldr.Initialized: Yes
  Ldr.InInitializationOrderModuleList: 71f40 . 77f68
  Ldr.InLoadOrderModuleList: 71ec0 . 77f58
  Ldr.InMemoryOrderModuleList: 71ec8 . 77f60
    01000000 C:\WINNT\system32\regsvc.exe
    77F80000 C:\WINNT\System32\ntdll.dll
    77DB0000 C:\WINNT\system32\ADVAPI32.dll
    77E80000 C:\WINNT\system32\KERNEL32.DLL
    77D40000 C:\WINNT\system32\RPCRT4.DLL
    77BE0000 C:\WINNT\system32\secur32.dll
  SubSystemData: 0
  ProcessHeap: 70000
  ProcessParameters: 20000
    WindowTitle: 'C:\WINNT\system32\regsvc.exe'
    ImageFile: 'C:\WINNT\system32\regsvc.exe'
    CommandLine: 'C:\WINNT\system32\regsvc.exe'
    DllPath:
'C:\WINNT\system32.;C:\WINNT\System32;C:\WINNT\system;C:\WINNT;C:\WINNT\system32;C:\WINNT;C:\WINNT\System32\W
bem;C:\PROGRA~1\COMMON~1\AUTODE~1'
    Environment: 0x10000
```

[Send comments about this topic to Microsoft](#)

.copysym (Copy Symbol Files)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.copysym** command copies the current symbol files to the specified directory.

```
.copysym [/l] Path
```

Parameters

/l

Causes each symbol file to be loaded as it is copied.

Path

Specifies the directory to which the symbol files should be copied. Copies do not overwrite existing files.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

Many times, symbols are stored on a network. The symbol access can often be slow, or you may need to transport your debugging session to another computer where you no longer have network access. In such scenarios, the **.copysym** command can be used to copy the symbols you need for your session to a local directory.

[Send comments about this topic to Microsoft](#)

.cordll (Control CLR Debugging)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.cordll** command controls managed code debugging and the Microsoft .NET common language runtime (CLR).

```
.cordll [Options]
```

Parameters

Options

One or more of the following options:

-l (lower-case L)

Loads the CLR debugging modules.

-I ** *Module*** (upper-case i)

Specifies the name or base address of the CLR module to be debugged. For more information, see Remarks.

-u

Unloads the CLR debugging modules.

-e

Enables CLR debugging.

-d

Disables CLR debugging.

-D

Disables CLR debugging and unloads the CLR debugging modules.

-N

Reloads the CLR debugging modules.

-lp ** *Path***

Specifies the directory path of the CLR debugging modules.

-se

Enables using the short name of the CLR debugging module, mscordacwks.dll.

-sd

Disables using the short name of the CLR debugging module, mscordacwks.dll. Instead, the debugger uses the long name of the CLR debugging module, mscordacwks_<spec>.dll. Turning off short name usage enables you to avoid having your local CLR used if you are concerned about mismatches.

-ve

Turns on verbose mode for CLR module loading.

-vd

Turns off verbose mode for CLR module loading.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

To debug a managed application, the debugger must load a data access component (DAC) that corresponds to the CLR that the application has loaded. However, in some cases, the application loads more than one CLR. In that case, you can use the **I** parameter to specify which DAC the debugger should load. Version 2 of the CLR is named `Mscorwks.dll`, and version 4 of the CLR is named `Clr.dll`. The following example shows how to specify that the debugger should load the DAC for version 2 (`mscorwks`).

```
.cordll -I mscorwks -lp c:\dacFolder
```

If you omit the **I** parameter, the debugger uses version 4 by default. For example, the following two commands are equivalent.

```
.cordll -lp c:\dacFolder
.cordll -I clr -lp c:\dacFolder
```

`Sos.dll` is a component that is used for debugging managed code. The current version of Debugging Tools for Windows does not include any version of `sos.dll`. For information about how to get `sos.dll`, see [Getting the SOS Debugging Extension \(`sos.dll`\)](#).

The **.cordll** command is supported in kernel-mode debugging. However, this command might not work unless the necessary memory is paged in.

See also

[Debugging Managed Code Using the Windows Debugger](#)

[SOS Debugging Extension](#)

[Send comments about this topic to Microsoft](#)

.crash (Force System Crash)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.crash** command causes the target computer to issue a bug check.

```
.crash
```

Environment

Modes	kernel mode only
Targets	live debugging only
Platforms	all

Additional Information

For an overview of related commands and a description of the options available after a system crash, see [Crashing and Rebooting the Target Computer](#).

Remarks

This command will immediately cause the target computer to crash.

If you are already in a bug check handler, do not use **.crash**. Use [g \(Go\)](#) instead to continue execution of the handler, which will generate a crash dump.

A kernel-mode dump file will be written if crash dumps have been enabled. See [Creating a Kernel-Mode Dump File](#) for details.

[Send comments about this topic to Microsoft](#)

.create (Create Process)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.create** command creates a new target application.

```
.create [-premote RemoteOptions] [-f] CommandLine
```

Parameters

RemoteOptions

Specifies a process server to which to attach. The options are the same as those for the command line **-premote** option. See [Activating a Smart Client](#) for syntax details.

-f

Freezes all threads in all target applications, except in the new target being created. These threads will remain frozen until an exception occurs in the newly-created process. Note that an initial breakpoint qualifies as an exception. Individual threads can be unfrozen by using the [~u \(Unfreeze Thread\)](#) command.

CommandLine

Specifies the complete command line for the new process. *CommandLine* may contain spaces, and must not be surrounded with quotes. All text after the **.create** command is taken as part of *CommandLine*; this command cannot be followed with a semicolon and additional debugger commands.

Environment

Modes	user mode only
Targets	live debugging only
Platforms	all

Remarks

This command can be used when CDB is dormant, or if it is already debugging one or more processes. It cannot be used when WinDbg is dormant.

If this command is successful, the debugger will create the specified process the next time the debugger issues an execution command. If this command is used several times in a row, execution will have to be requested as many times as this command was used.

Multiple target processes will always be executed together, unless some of their threads are frozen or suspended.

If you wish to create a new process and freeze all your existing targets, use the **-f** option.

If the **-premote** option is used, the new process will be part of a new system. For details, see [Debugging Multiple Targets](#).

[Send comments about this topic to Microsoft](#)

.createdir (Set Created Process Directory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.createdir** command controls the starting directory and handle inheritance for any processes created by the debugger.

```
.createdir [-i | -I] [Path]
```

Parameters

-i

Causes processes created by the debugger to inherit handles from the debugger. This is the default.

-I

Prevents processes created by the debugger from inheriting handles from the debugger.

Path

Specifies the starting directory for all child processes created by any target process. If *Path* contains spaces, it must be enclosed in quotation marks.

Environment

Modes	user mode only
Targets	live debugging only
Platforms	all

Remarks

If **.createdir** is used with no parameters, the current starting directory and handle inheritance status are displayed.

If **.createdir** has never been used, any created process will use its usual default directory as its starting directory. If you have already set a path with **.createdir** and want to return to the default status, use **.createdir ""** with nothing inside the quotation marks.

The **.createdir** setting affects all processes created by **.create (Create Process)**. It also affects processes created by WinDbg's **File | Open Executable** menu command, unless the **Start directory** text box is used to override this setting.

[Send comments about this topic to Microsoft](#)

.cxr (Display Context Record)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.cxr** command displays the context record saved at the specified address. It also sets the register context.

```
.cxr [Options] [Address]
```

Parameters

Options

Can be any combination of the following options:

/f ** Size**

Forces the context size to equal the value of *Size*, in bytes. This can be useful when the context does not match the actual target -- for example, when using an x86 context on a 64-bit target during [WOW64](#) debugging. If an invalid or inconsistent size is specified, the error "Unable to convert context to canonical form" will be displayed.

/w

Writes the current context to memory, and displays the address of the location where it was written.

Address

Address of the system context record.

Omitting the address does not display any context record information, but it does reset the register context.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

Remarks

The information from a context record can be used to assist in debugging a system halt where an unhandled exception has occurred and an exact stack trace is not available. The **.cxr** command displays the important registers for the specified context record.

This command also instructs the debugger to use the specified context record as the register context. After this command is executed, the debugger will have access to the most important registers and the stack trace for this thread. This register context persists until you allow the target to execute or use another register context command ([.thread](#), [.ecxr](#), [.trap](#), or **.cxr** again). In user mode, it will also be reset if you change the current process or thread. See [Register Context](#) for details.

The **.cxr** command is often used to debug bug check 0x1E. For more information and an example, see [Bug Check 0x1E \(KMODE_EXCEPTION_NOT_HANDLED\)](#).

The **.cxr /w** command writes the context to memory and displays the address where it has been stored. This address can be passed to [.apply_dbp \(Apply Data Breakpoint to Context\)](#) if you need to apply data breakpoints to this context.

[Send comments about this topic to Microsoft](#)

.dbgdbg (Debug Current Debugger)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.dbgdbg** command launches a new instance of CDB; this new debugger takes the current debugger as its target.

```
.dbgdbg
```

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

The **.dbgdbg** command is similar to the [CTRL+P \(Debug Current Debugger\)](#) control key. However, **.dbgdbg** is more versatile, because it can be used from WinDbg as well as KD and CDB, and it can be used to debug a debugging server on a remote computer.

[Send comments about this topic to Microsoft](#)

.detach (Detach from Process)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.detach** command ends the debugging session, but leaves any user-mode target application running.

```
.detach [ /h | /n ]
```

Parameters

/h

Any outstanding debug event will be continued and marked as handled. This is the default.

/n

Any outstanding debug event will be continued without being marked as handled.

Environment

For live user-mode debugging, this command is only supported in Windows XP and later versions of Windows.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

This command will end the debugging session in any of the following scenarios:

- When you are debugging a user-mode or kernel-mode dump file.
- (Windows XP and later) When you are debugging a live user-mode target.
- When you are noninvasively debugging a user-mode target.

If you are only debugging a single target, the debugger will return to dormant mode after it detaches.

If you are [debugging multiple targets](#), the debugging session will continue with the remaining targets.

[Send comments about this topic to Microsoft](#)

.dml_flow (Unassemble with Links)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.dml_flow** command displays a disassembled code block and provides links that you can use to construct a code flow graph.

```
.dml_flow Start Target
```

Parameters

Start

The address of an instruction from which the target address can be reached.

Target

An address in the code block to be disassembled.

Remarks

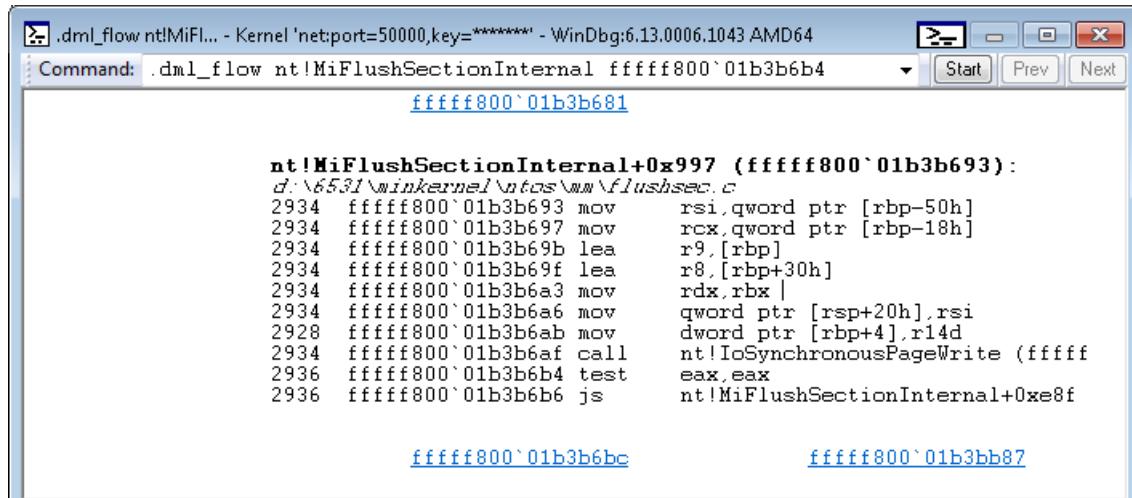

Consider the call stack shown in the following example.

```
0: kd> kL
Child-SP      RetAddr      Call Site
fffff880`0335c688 fffff800`01b41f1c nt!IoCallDriver
fffff880`0335c690 fffff800`01b3b6b4 nt!IoSynchronousPageWrite+0x1cc
fffff880`0335c700 fffff800`01b4195e nt!MiFlushSectionInternal+0x9b8
...
...
```

Suppose you want to examine all code paths from the start of **nt!MiFlushSectionInternal** to the code block that contains the return address, `fffff800`01b3b6b4`. The following command gets you started.

```
.browse .dml_flow nt!MiFlushSectionInternal fffff800`01b3b6b4
```

The output, in the [Command Browser window](#), is shown in the following image.

```
nt!MiFlushSectionInternal+0x997 (fffff800`01b3b693):
d:\6531\winkernel\ntos\mm\flushsec.c
2934  fffff800`01b3b693 mov    rsi,qword ptr [rbp-50h]
2934  fffff800`01b3b697 mov    rcx,qword ptr [rbp-18h]
2934  fffff800`01b3b69b lea    r9,[rbp]
2934  fffff800`01b3b69f lea    r8,[rbp+30h]
2934  fffff800`01b3b6a3 mov    rdx,rbx
2934  fffff800`01b3b6a6 mov    qword ptr [rsp+20h],rsi
2928  fffff800`01b3b6ab mov    dword ptr [rbp+4],r14d
2934  fffff800`01b3b6af call   nt!IoSynchronousPageWrite (fffff
2936  fffff800`01b3b6b4 test   eax,eax
2936  fffff800`01b3b6b6 js    nt!MiFlushSectionInternal+0xe8f

fffff800`01b3b6bc          fffff800`01b3b687
```

The preceding image shows the code block that contains the target address, `fffff800`01b3b6b4`. There is only one

link ([fffff800`01b3b681](#)) at the top of the image. That indicates that there is only one code block from which the current code block can be reached. If you click the link, you will see that code block disassembled, and you will see links that enable you to further explore the code flow graph.

The two links at the bottom of the preceding image indicate that there are two code blocks that can be reached from the current code block.

[Debugger Markup Language Commands](#)

[uf \(Unassemble Function\)](#)

[Send comments about this topic to Microsoft](#)

.dml_start (Display DML Starting Point)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.dml_start** command displays output that serves as a starting point for exploration using commands that support [Debugger Markup Language \(DML\)](#).

```
.dml_start
.dml_start filename
```

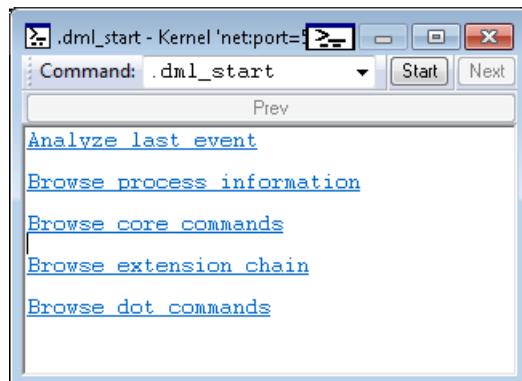

Parameters

filename

The name of a DML file to be displayed as the starting output.

Using the Default Starting Output

If *filename* is omitted, the debugger displays a default DML starting output as illustrated in the following image.

Each line of output in the preceding example is a link that you can click to invoke other commands.

Providing a DML File

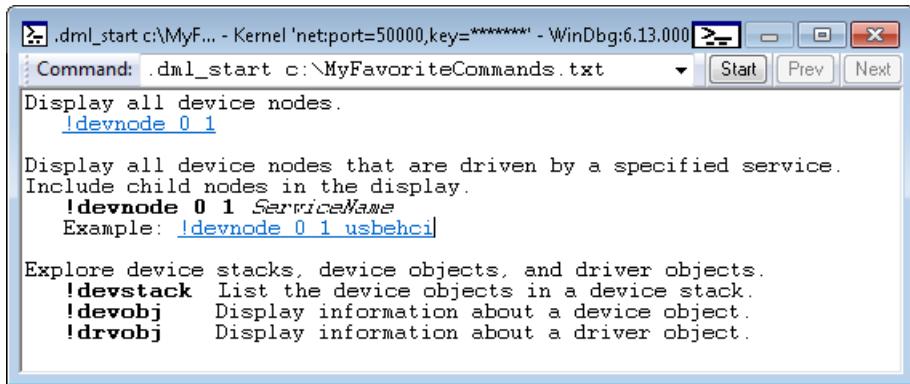

If you supply a path to a DML file, the file is used as the starting output. For example, suppose the file `c:\MyFavoriteCommands.txt` contains the following text and DML tags.

```
Display all device nodes.
<link cmd="!devnode 0 1">!devnode 0 1</link>

Display all device nodes that are driven by a specified service.
Include child nodes in the display.
<b>!devnode 0 1</b> <i>ServiceName</i>
Example: <link cmd="!devnode 0 1 usbehci">!devnode 0 1 usbehci</link>

Explore device stacks, device objects, and driver objects.
<b>!devstack</b> List the device objects in a device stack.
<b>!devobj</b> Display information about a device object.
<b>!drvobj</b> Display information about a driver object.
```

The command **.dml_start c:\MyFavoriteCommands.txt** will display the file as shown in the following image.

The screenshot shows the WinDbg Command Browser window with the title ".dml_start c:\MyF... - Kernel 'net:port=50000,key=*****' - WinDbg:6.13.000". The command input field contains ".dml_start c:\MyFavoriteCommands.txt". The main pane displays the following text:

```
Display all device nodes.
!devnode 0 1

Display all device nodes that are driven by a specified service.
Include child nodes in the display.
!devnode 0 1 ServiceName
Example: !devnode 0 1 usbehci

Explore device stacks, device objects, and driver objects.
!devstack List the device objects in a device stack.
!devobj Display information about a device object.
!drvobj Display information about a driver object.
```

Remarks

For information about DML tags that can be used in DML files, see [dml.doc](#) in the installation folder for Debugging Tools for Windows.

DML output often works well in the [Command Browser window](#). To display a DML file in the Command Browser window, use **.browse .dml_start filename**.

See also

[Debugger Markup Language Commands](#)

.browse

[Send comments about this topic to Microsoft](#)

.dump (Create Dump File)

5/31/2017 • 6 min to read • [Edit Online](#)

The **.dump** command creates a user-mode or kernel-mode crash dump file.

```
.dump Options FileName  
.dump /?
```

Parameters

Options

Represents one or more of the following options

/o

Overwrites an existing dump file with the same name. If this option is not used and there is a file with the same file name, the dump file is not written.

/f[FullOptions]

(Kernel mode:) Creates a [complete memory dump](#).

(User mode:) Creates a [full user-mode dump](#). Despite their names, the largest minidump file actually contains more information than a full user-mode dump. For example, **.dump /mf** or **.dump /ma** creates a larger and more complete file than **.dump /f**. In user mode, **.dump /m[MiniOptions]** is always preferable to **.dump /f**.

You can add the following *FullOptions* to change the contents of the dump file; the option is case-sensitive.

FullOption	Effect
y	Adds AVX register information to the dump file.

/m[MiniOptions]

Creates a [small memory dump](#) (in kernel mode) or a [minidump](#) (in user mode). If neither **/f** nor **/m** is specified, **/m** is the default.

In user mode, **/m** can be followed with additional *MiniOptions* specifying extra data that is to be included in the dump. If no *MiniOptions* are included, the dump will include module, thread, and stack information, but no additional data. You can add any of the following *MiniOptions* to change the contents of the dump file; they are case-sensitive.

MINIOPTION	EFFECT
a	Creates a minidump with all optional additions. The /ma option is equivalent to /mfFhut -- it adds full memory data, handle data, unloaded module information, basic memory information, and thread time information to the minidump. Any failure to read inaccessible memory results in termination of the minidump generation.

MINIOPTION	EFFECT
A	The /mA option is equivalent to /ma except that it ignores any failure to read inaccessible memory and continues generating the minidump.
f	Adds full memory data to the minidump. All accessible committed pages owned by the target application will be included.
F	Adds all basic memory information to the minidump. This adds a stream to the minidump that contains all basic memory information, not just information about valid memory. This allows the debugger to reconstruct the complete virtual memory layout of the process when the minidump is being debugged.
h	Adds data about the handles associated with the target application to the minidump.
u	Adds unloaded module information to the minidump. This is available only in Windows Server 2003 and later versions of Windows.
t	Adds additional thread information to the minidump. This includes thread times, which can be displayed by using the !runaway extension or the .ttime (Display Thread Times) command when debugging the minidump.
i	Adds <i>secondary memory</i> to the minidump. Secondary memory is any memory referenced by a pointer on the stack or backing store, plus a small region surrounding this address.
p	Adds process environment block (PEB) and thread environment block (TEB) data to the minidump. This can be useful if you need access to Windows system information regarding the application's processes and threads.
w	Adds all committed read-write private pages to the minidump.
d	Adds all read-write data segments within the executable image to the minidump.
c	Adds code sections within images.

MINIOPTION	EFFECT
r	Deletes from the minidump those portions of the stack and store memory that are not useful for recreating the stack trace. Local variables and other data type values are deleted as well. This option does not make the minidump smaller (because these memory sections are simply zeroed), but it is useful if you want to protect the privacy of other applications.
R	Deletes the full module paths from the minidump. Only the module names will be included. This is a useful option if you want to protect the privacy of the user's directory structure.
y	Adds AVX register information to the dump file.

These *MiniOptions* can only be used when creating a user-mode minidump. They should follow the **/m** specifier.

/u

Appends the date, time, and PID to the dump file names. This ensures that dump file names are unique.

/a

Generates dumps for all currently-debugged processes. If **/a** is used, the **/u** option should also be used to ensure that each file has a unique name.

/b[a]

Creates a .cab file. If this option is included, *FileName* is interpreted as the CAB file name, not the dump file name. A temporary dump file will be created, this file will be packaged into a CAB, and then the dump file will be deleted. If the **b** option is followed by **a**, all symbol and image files also will be packaged into the CAB.

/c "Comment"

Specifies a comment string that will be written to the dump file. If *Comment* contains spaces, it must be enclosed in double quotes. When the dump file is loaded, the *Comment* string will be displayed.

/xc Address

(User mode minidumps only) Adds a context record to the dump file. *Address* must specify the address of the context record.

/xr Address

(User mode minidumps only) Adds an exception record to the dump file. *Address* must specify the address of the exception record.

/xp Address

(User mode minidumps only) Adds a context record and an exception record to the dump file. *Address* must specify the address of an EXCEPTION_POINTERS structure which contains pointers to the context record and the exception record.

/xt ThreadID

(User mode minidumps only) Specifies the thread ID of the system thread that will be used as the exception thread for this dump file.

/kpmf File

(Only when creating a kernel-mode Complete Memory Dump) Specifies a file that contains physical memory page data.

/j Address

Adds the JIT_DEBUG_INFO structure to the dump file in user mode. *Address* must specify the address of the JIT_DEBUG_INFO structure. This address is normally provided via the %p parameter when the jdinfo command is used as part of a just in time postmortem debugging process. For more information, see [.jdinfo \(Use JIT_DEBUG_INFO\)](#) and [Enabling Postmortem Debugging](#).

FileName

Specifies the name of the dump file. You can specify a full path and file name or just the file name. If the file name contains spaces, *FileName* should be enclosed in quotation marks. If no path is specified, the current directory is used.

-?

Displays help for this command. This text is different in kernel mode and in user mode.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For a description of kernel-mode dump files and an explanation of their use, see [Kernel-Mode Dump Files](#). For a description of user-mode dump files and an explanation of their use, see [User-Mode Dump Files](#).

Remarks

This command can be used in a variety of situations:

- During live user-mode debugging, this command directs the target application to generate a dump file, but the target application does not terminate.
- During live kernel-mode debugging, this command directs the target computer to generate a dump file, but the target computer does not crash.
- During crash dump debugging, this command creates a new crash dump file from the old one. This is useful if you have a large crash dump file and want to create a smaller one.

You can control what type of dump file will be produced:

- In kernel mode, to produce a [complete memory dump](#), use the **/f** option. To produce a [small memory dump](#), use the **/m** option (or no options). The **.dump** command cannot produce a [kernel memory dump](#).
- In user mode, **.dump /m[*MiniOptions*]** is the best choice. Although "m" stands for "minidump", the dump files created by using this *MiniOption* can vary in size from very small to very large. By specifying the proper *MiniOptions* you can control exactly what information is included. For example, **.dump /ma** produces a dump with a great deal of information. The older command, **.dump /f**, produces a moderately large "standard dump" file and cannot be customized.

You cannot specify which process is dumped. All running processes will be dumped.

The **/xc**, **/xr**, **/xp**, and **/xt** options are used to store exception and context information in the dump file. This allows the [.ecxr \(Display Exception Context Record\)](#) command to be run on this dump file.

The following example will create a user-mode minidump, containing full memory and handle information:

```
0:000> .dump /mfh myfile.dmp
```

Handle information can be read by using the **!handle** extension command.

[Send comments about this topic to Microsoft](#)

.dumpcab (Create Dump File CAB)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.dumpcab** command creates a CAB file containing the current dump file.

```
.dumpcab [-a] CabName
```

Parameters

-a

Causes all currently loaded symbols to be included in the CAB file. For minidumps, all loaded images will be included as well. Use [!ml](#) to determine which symbols and images are loaded.

CabName

The CAB file name, including extension. *CabName* can include an absolute or relative path; relative paths are relative to the directory in which the debugger was started. It is recommended that you choose the extension .cab.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For more details on crash dumps, see [Crash Dump Files](#).

Remarks

This command can only be used if you are already debugging a dump file.

If you are debugging a live target and want to create a dump file and place it in a CAB, you should use the [.dump \(Create Dump File\)](#) command. Next, start a new debugging session with the dump file as its target, and use **.dumpcab**.

The **.dumpcab** command cannot be used to place multiple dump files into one CAB file.

[Send comments about this topic to Microsoft](#)

.dvalloc (Allocate Memory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.dvalloc** command causes Windows to allocate additional memory to the target process.

```
.dvalloc [Options] Size
```

Parameters

Options

Can be any number of the following options:

/b ** BaseAddress**

Specifies the virtual address of the beginning of the allocation.

/r

Reserves the memory in the virtual address space but does not actually allocate any physical memory. If this option is used, the debugger calls **VirtualAllocEx** with the *fAllocationType* parameter equal to `MEM_RESERVE`. If this option is not used, the value `MEM_COMMIT | MEM_RESERVE` is used. See the Microsoft Windows SDK for details.

Size

Specifies the amount of memory to be allocated, in bytes. The amount of memory available to the program will equal *Size*. The amount of memory actually used may be slightly larger, since it is always a whole number of pages.

Environment

Modes	user mode only
Targets	live debugging only
Platforms	all

Remarks

The **.dvalloc** command calls **VirtualAllocEx** to allocate new memory for the target process. The allocated memory permits reading, writing, and execution.

To free this memory, use [.dvfree \(Free Memory\)](#).

[Send comments about this topic to Microsoft](#)

.dvfree (Free Memory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.dvfree** command frees a memory allocation owned by the target process.

```
.dvfree [/d] BaseAddress Size
```

Parameters

/d

Decommits the allocation, but does not actually release the pages containing the allocation. If this option is used, the debugger calls **VirtualFreeEx** with the *dwFreeType* parameter equal to `MEM_DECOMMIT`. If this option is not used, the value `MEM_RELEASE` is used. See the Microsoft Windows SDK for details.

BaseAddress

Specifies the virtual address of the beginning of the allocation.

Size

Specifies the amount of memory to be freed, in bytes. The actual memory freed will always be a whole number of memory pages.

Environment

Modes	user mode only
Targets	live debugging only
Platforms	all

Remarks

The **.dvfree** command calls **VirtualFreeEx** to free an existing memory allocation. Unless the **/d** option is specified, the pages containing this memory are released.

This command can be used to free an allocation made by [.dvalloc \(Allocate Memory\)](#). It can also be used to free any block of memory owned by the target process, but freeing memory that was not acquired through **.dvalloc** will naturally pose risks to the stability of the target process.

[Send comments about this topic to Microsoft](#)

.echo (Echo Comment)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.echo** command displays a comment string.

```
.echo String
.echo "String"
```

Parameters

String

Specifies the text to display. You can also enclose *String* in quotation marks (''). Regardless of whether you use quotation marks, *String* can contain any number of spaces, commas, and single quotation marks (''). If you enclose *String* in quotation marks, it can include semicolons, but not additional quotation marks. If you do not enclose *String* in quotation marks, it can include quotation marks in any location except the first character, but it cannot include semicolons.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.echo** command causes the debugger to display *String* immediately after you enter the command.

An **.echo** command is ended if the debugger encounters a semicolon (unless the semicolon occurs within a quoted string). This restriction enables you to use **.echo** in complex constructions such as [conditional breakpoints](#), as the following example shows.

```
0:000> bp `:143` "j (poi(MyVar)>5) '.echo MyVar Too Big'; '.echo MyVar Acceptable; gc' "
```

The **.echo** command also provides an easy way for users of debugging servers and debugging clients to communicate with one another. For more information about this situation, see [Controlling a Remote Debugging Session](#).

The **.echo** command differs from the **\$\$ (Comment Specifier)** token and the *** (Comment Line Specifier)** token, because these tokens cause the debugger to ignore the input text without displaying it.

[Send comments about this topic to Microsoft](#)

.echocpnum (Show CPU Number)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.echocpnum** command turns on or turns off the display of the processor number when you are debugging a multiprocessor target computer.

```
.echocpnum 0
.echocpnum 1
.echocpnum
```

Parameters

0

Turns off the display of the processor number.

1

Turns on the display of the processor number.

Environment

Modes	Kernel mode only
Targets	Live debugging only
Platforms	All

Additional Information

For more information about how to debug multiprocessor computers, see [Multiprocessor Syntax](#).

Remarks

If you use the **.echocpnum** command without any arguments, the display of processor numbers is turned on or off, and the new state is displayed.

By default, the display is turned off.

[Send comments about this topic to Microsoft](#)

.echotime (Show Current Time)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.echotime** command displays the current time.

```
.echotime
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.echotime** command displays the time to the computer that the debugger is running on.

[Send comments about this topic to Microsoft](#)

.echotimestamps (Show Time Stamps)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.echotimestamps** command turns on or turns off the display of time stamp information.

```
.echotimestamps 0
.echotimestamps 1
.echotimestamps
```

Parameters

0

Turns off the display of time stamp information. This is the default behavior of the Debugger.

1

Turns on the display of time stamp information.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about **DbgPrint**, **KdPrint**, **DbgPrintEx**, and **KdPrintEx**, see [The DbgPrint Buffer](#) or see the Microsoft Windows Driver Kit (WDK) documentation.

Remarks

When you use the **.echotimestamps** command without parameters, the display of time stamps is turned on or off, and the new state is displayed.

If you turn on this display, the debugger shows time stamps for module loads, thread creations, exceptions, and other events.

The **DbgPrint**, **KdPrint**, **DbgPrintEx**, and **KdPrintEx** kernel-mode routines send a formatted string to a buffer on the host computer. The string is displayed in the [Debugger Command window](#) (unless you have disabled such printing). You can also display the formatted string by using the **!dbgprint** extension command.

When you use **.echotimestamps** to turn on the display of time stamps, the time and date of each comment in the **DbgPrint** buffer is displayed.

[Send comments about this topic to Microsoft](#)

.ecxr (Display Exception Context Record)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.ecxr** command displays the context record that is associated with the current exception.

```
.ecxr
```

Environment

Modes	User mode only
Targets	Crash dump only (minidumps only)
Platforms	All

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

Remarks

The **.ecxr** command locates the current exception's context information and displays the important registers for the specified context record.

This command also instructs the debugger to use the context record that is associated with the current exception as the register context. After you run **.ecxr**, the debugger can access the most important registers and the stack trace for this thread. This register context persists until you enable the target to execute, change the current process or thread, or use another register context command ([.cxr](#) or [.ecxr](#)). For more information about register contexts, see [Register Context](#).

The [.excr](#) command is a synonym command and has identical functionality.

See also

[.excr](#)

[Send comments about this topic to Microsoft](#)

.effmach (Effective Machine)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.effmach** command displays or changes the processor mode that the debugger uses.

```
.effmach [MachineType]
```

Parameters

MachineType

Specifies the processor type that the debugger uses for this session. If you omit this parameter, the debugger displays the current machine type.

You can enter one of the following machine types.

Machine type	Description
.	Use the processor mode of the target computer's native processor mode.
#	Use the processor mode of the code that is executing for the most recent event.
x86	Use an x86-based processor mode.
amd64	Use an x64-based processor mode.
ebc	Use an EFI byte code processor mode.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The processor mode influences many debugger features:

- Which processor is used for stack tracing.
- Whether the process uses 32-bit or 64-bit pointers.

- Which processor's register set is active.

[Send comments about this topic to Microsoft](#)

.enable_long_status (Enable Long Integer Display)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.enable_long_status** command specifies whether the debugger displays long integers in decimal format or in the default radix.

```
.enable_long_status 0
.enable_long_status 1
```

Parameters

0

Displays all long integers in decimal format. This is the default behavior of the debugger.

1

Displays all long integers in the default radix.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.enable_long_status** command affects the output of the [dt \(Display Type\)](#) command.

In WinDbg, **.enable_long_status** also affects the display in the [Locals window](#) and the Watch window. These windows are automatically updated after you issue **.enable_long_status**.

This command affects only the display of long integers. To control whether standard integers are displayed in decimal format or the default radix, use the [.force_radix_output \(Use Radix for Integers\)](#) command.

Note The [dv \(Display Local Variables\)](#) command always displays long integers in the current number base.

To change the default radix, use the [n \(Set Number Base\)](#) command.

[Send comments about this topic to Microsoft](#)

.enable_unicode (Enable Unicode Display)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.enable_unicode** command specifies whether the debugger displays USHORT pointers and arrays as Unicode strings.

```
.enable_unicode 0
.enable_unicode 1
```

Parameters

0

Displays all 16-bit (USHORT) arrays and pointers as short integers. This is the default behavior of the debugger.

1

Displays all 16-bit (USHORT) arrays and pointers as Unicode strings.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.enable_unicode** command affects the output of the [dt \(Display Type\)](#) command.

In WinDbg, the **.enable_unicode** command also affects the display in the [Locals window](#) and the Watch window. These windows are automatically updated after you issue **.enable_unicode**.

You can also select or clear **Display 16-bit values** as Unicode on the shortcut menu of the Locals or Watch window to specify the display for USHORT arrays and pointers.

See also

[ds, dS \(Display String\)](#)

[Send comments about this topic to Microsoft](#)

.endpsrv (End Process Server)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.endpsrv** command causes the current process server or KD connection server to close.

```
.endpsrv
```

Environment

You can use this command only when you are performing remote debugging through a process server or KD connection server.

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about these servers, see [Process Servers \(User Mode\)](#) or [KD Connection Servers \(Kernel Mode\)](#)

Remarks

The **.endpsrv** command terminates the process server or KD connection server currently connected to your smart client.

If you wish to terminate a process server or KD connection server from the computer on which it is running, use Task Manager to end the process (dbgsrv.exe or kdsrv.exe).

The **.endpsrv** command can terminate a process server or KD connection server, but it cannot terminate a debugging server. For information on how to do that, see [Controlling a Remote Debugging Session](#).

[Send comments about this topic to Microsoft](#)

.endsrv (End Debugging Server)

5/31/2017 • 2 min to read • [Edit Online](#)

The **.endsrv** command causes the debugger to cancel an active debugging server.

```
.endsrv ServerID
```

Parameters

ServerID

Specifies the ID of the debugging server.

Environment

You can use this command only when you are performing remote debugging through the debugger.

Modes	User mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about remote debugging, see [Remote Debugging Through the Debugger](#).

Remarks

You must issue the **.endsrv** command from the debugging server or from one of the debugging clients that are connected to the debugging server.

To determine the ID of a debugging server, use the [.servers \(List Debugging Servers\)](#) command.

The **.endsrv** command can terminate a debugging server, but it cannot terminate a process server or KD connection server. For information on how to end these servers, see [Controlling a Process Server Session](#) and [Controlling a KD Connection Server Session](#). (There is, however, one exceptional case when **.endsrv** can end a process server that has been launched programmatically; for details, see [IDebugClient::StartProcessServer](#).)

If you cancel a debugging server, you prevent any future debugging clients from attaching to the server. However, if you cancel a debugging server, you do not detach any clients that are currently attached through the server.

Consider the following situation. Suppose that you start some debugging servers, as the following example shows.

```
0:000> .server npipe:pipe=rabbit
Server started with 'npipe:pipe=rabbit'
0:000> .server tcp:port=7
Server started with 'tcp:port=7'
```

Then, you decide to use a password, as the following example shows.

```
0:000> .server npipe:pipe=tiger,password=hardtoguess
Server started with 'npipe:pipe=tiger,password=hardtoguess'
```

But the earlier servers are still running, so you should cancel them, as the following example shows.

```
0:000> .servers
0 - Debugger Server - npipe:Pipe=rabbit
1 - Debugger Server - tcp:Port=7
2 - Debugger Server - npipe:Pipe=tiger,Password=*
0:000> .endsrv 0
Server told to exit. Actual exit may be delayed until
the next connection attempt.
0:000> .endsrv 1
Server told to exit. Actual exit may be delayed until
the next connection attempt.
0:000> .servers
0 - <Disabled, exit pending>
1 - <Disabled, exit pending>
2 - Debugger Server - npipe:Pipe=tiger,Password=*
```

Finally, to make sure that nothing attached to your computer while the earlier servers were active, use the [.clients](#) ([List Debugging Clients](#)) command.

```
0:000> .clients
HotMachine\HostUser, last active Mon Mar 04 16:05:21 2002
```

Caution Using a password with TCP, NPIPE, or COM protocol offers only a small amount of protection, because the password is not encrypted. When you use a password together with a SSL or SPIPE protocol, the password is encrypted. If you want to establish a secure remote session, you must use the SSL or SPIPE protocol.

[Send comments about this topic to Microsoft](#)

.enumtag (Enumerate Secondary Callback Data)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.enumtag** command displays secondary bug check callback data and all data tags.

```
.enumtag
```

Environment

Modes	Kernel mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information and for other ways of displaying this data, see [Reading Bug Check Callback Data](#).

Remarks

You can use the **.enumtag** command only after a bug check has occurred or when you are debugging a kernel-mode crash dump file.

For each block of secondary bug check callback data, the **.enumtag** command displays the tag (in GUID format) and the data (as bytes and ASCII characters).

Consider the following example.

```
kd> .enumtag
{87654321-0000-0000-0000000000000000} - 0xf9c bytes
 4D 5A 90 00 03 00 00 00 04 00 00 00 FF FF 00 00  MZ.....
  B8 00 00 00 00 00 00 40 00 00 00 00 00 00 00 00  .....@.....
  00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00  .....'.
  ...
  00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00  .....

{12345678-0000-0000-0000000000000000} - 0x298 bytes
  F4 BF 7B 80 F4 BF 7B 80 00 00 00 00 00 00 00 00  ..{.....
  4B 44 42 47 98 02 00 00 00 20 4D 80 00 00 00 00  KDBG.... M.....
  54 A5 57 80 00 00 00 00 A0 50 5A 80 00 00 00 00  T.W.....PZ.....
  40 01 08 00 18 00 00 00 BC 7D 50 80 00 00 00 00  @.....}P.....
  ...
  00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00  .....
```

In this example, the first batch of secondary data has a GUID `{87654321-0000-0000-0000000000000000}` as its tag, and the second batch of data has a GUID `{12345678-0000-0000-0000000000000000}` as its tag. However, the data is not in a useful format.

[Send comments about this topic to Microsoft](#)

.event_code (Display Event Code)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.event_code** command displays the current event instructions.

```
.event_code
```

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	All

Remarks

The **.event_code** command displays the hexadecimal instructions at the current event's instruction pointer. The display includes up to 64 bytes of instructions if they are available.

[Send comments about this topic to Microsoft](#)

.eventlog (Display Recent Events)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.eventlog** command displays the recent Microsoft Win32 debug events, such as module loading, process creation and termination, and thread creation and termination.

```
.eventlog
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.eventlog** command shows only 1024 characters.

The following example shows the **.eventlog** command.

```
0:000> .eventlog
0904.1014: Load module C:\Windows\system32\ADVAPI32.dll at 000007fe`fed80000
0904.1014: Load module C:\Windows\system32\RPCRT4.dll at 000007fe`fe8c0000
0904.1014: Load module C:\Windows\system32\GDI32.dll at 000007fe`fea00000
0904.1014: Load module C:\Windows\system32\USER32.dll at 00000000`76b10000
0904.1014: Load module C:\Windows\system32\msvcrt.dll at 000007fe`fe450000
0904.1014: Load module C:\Windows\system32\COMDLG32.dll at 000007fe`fecf0000
0904.1014: Load module C:\Windows\system32\SHLWAPI.dll at 000007fe`fe1f0000
0904.1014: Load module C:\Windows\WinSxS\amd64_microsoft.windows.common-controls_6595b6414
4ccf1df_6.0.6000.16386_none_1559f1c6f365a7fa\COMCTL32.dll at 000007fe`fbda0000
0904.1014: Load module C:\Windows\system32\SHELL32.dll at 000007fe`fd4a0000
0904.1014: Load module C:\Windows\system32\WINSPOOL.DRV at 000007fe`f77d0000
0904.1014: Load module C:\Windows\system32\ole32.dll at 000007fe`feb10000
0904.1014: Load module C:\Windows\system32\OLEAUT32.dll at 000007fe`feeb0000
Last event: Break instruction exception - code 80000003 (first chance)
```

[Send comments about this topic to Microsoft](#)

.exepath (Set Executable Path)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.exepath** command sets or displays the executable file search path.

```
.exepath[+] [Directory [; ...]]
```

Parameters

+

Specifies that the debugger should append the new directories to the previous executable file search path (instead of replacing the path).

Directory

Specifies one or more directories to put in the search path. If you do not specify *Directory*, the current path is displayed. You can separate multiple directories with semicolons.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

[Send comments about this topic to Microsoft](#)

.expr (Choose Expression Evaluator)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.expr** command specifies the default expression evaluator.

```
.expr /s masm
.expr /s c++
.expr /q
.expr
```

Parameters

/s masm

Changes the default expression type to Microsoft Assembler expression evaluator (MASM). This type is the default value when you start the debugger.

/s c++

Changes the default expression type to the C++ expression evaluator.

/q

Displays the list of possible expression types.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

When you use the **.expr** command without an argument, the debugger displays the current default expression type.

The [?? \(Evaluate C++ Expression\)](#) command, the

Watch window, and the [Locals window](#) always use C++ expression syntax. All other commands and debugging information windows use the default expression evaluator.

For more information about how to control which syntax is used, see [Evaluating Expressions](#). For more information about the syntax, see [Numerical Expression Syntax](#).

[Send comments about this topic to Microsoft](#)

.expr (Display Exception Pointers)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.expr** command displays an EXCEPTION_POINTERS structure.

```
.expr Address
```

Parameters

Address

Specifies the address of the EXCEPTION_POINTERS structure.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

[Send comments about this topic to Microsoft](#)

.exr (Display Exception Record)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.exr** command displays the contents of an exception record.

```
.exr Address
.exr -1
```

Parameters

Address

Specifies the address of the exception record. If you specify **-1** as the address, the debugger displays the most recent exception.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.exr** command displays information that is related to an exception that the debugger encountered on the target computer. The information that is displayed includes the exception address, the exception code, the exception flags, and a variable list of parameters to the exception.

You can usually obtain the *Address* by using the [!pcre](#) extension.

The **.exr** command is often used to debug bug check 0x1E. For more information and an example, see [Bug Check 0x1E \(KMODE_EXCEPTION_NOT_HANDLED\)](#).

[Send comments about this topic to Microsoft](#)

.excr (Display Exception Context Record)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.excr** command displays the context record that is associated with the current exception.

```
.excr
```

Environment

Modes	User mode only
Targets	Crash dump only (minidumps only)
Platforms	All

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

Remarks

The **.excr** command locates the current exception's context information and displays the important registers for the specified context record.

This command also instructs the debugger to use the context record that is associated with the current exception as the register context. After you run **.excr**, the debugger can access the most important registers and the stack trace for this thread. This register context persists until you enable the target to execute, change the current process or thread, or use another register context command (**.cxr** or **.excr**). For more information about register contexts, see [Register Context](#).

The **.ecxr** command is a synonym command and has identical functionality.

See also

[.ecxr](#)

[Send comments about this topic to Microsoft](#)

.extmatch (Display All Matching Extensions)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.extmatch** command displays extension commands exported by the currently loaded extension DLLs that match the specified pattern.

```
.extmatch [Options] Pattern
```

Parameters

Options

Specifies the searching options. You can use one or more of the following options:

/e **** ExtDLLPattern

Limits the enumeration to extension commands exported by extension DLLs that match the specified pattern string. *ExtDLLPattern* is matched against the extension DLL filename.

/n

Excludes the extension name when the extensions are displayed. Thus, if this option is specified, then only the extension name itself will be displayed.

/D

Displays the output using [Debugger Markup Language \(DML\)](#). In the output, each listed extension is a link that you can click to get more information about the extension. Not all extension modules support DML.

Pattern

Specifies a pattern that the extension must contain. *Pattern* can contain a variety of wildcard characters and specifiers. For more information about the syntax, see [String Wildcard Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

To display a list of loaded extension DLLs, use the [.chain](#) command.

Here is an example of this command, showing all the loaded extension DLLs that have an export named !help:

```
0:000> .extmatch help
!ext.help
!exts.help
!uext.help
!ntsdeexts.help
```

The following example lists all extension commands beginning with the string "he" that are exported by extension DLLs whose names begin with the string "ex":

```
0:000> .extmatch /e ext* he*
!ext.heap
!ext.help
!exts.heap
!exts.help
```

The following example lists all extension commands, so we can see which ones support DML.

[Send comments about this topic to Microsoft](#)

.expth (Set Extension Path)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.expth** command sets or displays the extension DLL search path.

```
.expth[+] [Directory[;...]]
```

Parameters

+

Signifies that the debugger should append new directories to the previous extension DLL search path (instead of replacing the path).

Directory

Specifies one or more directories to put in the search path. If you do not specify *Directory*, the current path is displayed. You can separate multiple directories with semicolons.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about the extension search path and loading extension DLLs, see [Loading Debugger Extension DLLs](#).

Remarks

The extension DLL search path is reset to its default value at the start of each debugging session.

During live kernel-mode debugging, a reboot of the target computer results in the start of a new debugging session. So any changes that you make to the extension DLL search path during kernel-mode debugging will not persist across a reboot of the target computer.

The default value of the extension DLL search path contains all the extension paths known to the debugger and all the paths in the %PATH% environment variable. For example, suppose your %PATH% environment variable has a value of `C:\Windows\system32;C:\Windows`. Then the default value of the DLL extension search path might look like this.

```
0:000> .expth
Extension search path is: C:\Program Files\Debugging Tools for Windows (x64)\WINXP;C:\Program Files\Debugging Tools for Windows (x64)\winext;C:\Program Files\Debugging Tools for Windows (x64)\winext\arcade;C:\Program Files\Debugging Tools for Windows (x64);C:\Program Files\Debugging Tools for Windows (x64)\winext\arcade;C:\Windows\system32;C:\Windows
```

[Send comments about this topic to Microsoft](#)

.f+, .f- (Shift Local Context)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.f+** command shifts the frame index to the next frame in the current stack. The **.f-** command shifts the frame index to the previous frame in the current stack.

```
.f+
.f-
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about the local context and other context settings, see [Changing Contexts](#). For more information about how to display local variables and other memory-related commands, see [Reading and Writing Memory](#).

Remarks

The *frame* specifies the local context (scope) that the debugger uses to interpret local variables

The **.f+** and **.f-** commands are shortcuts for moving to the next and previous frames in the current stack. These commands are equivalent to the following **.frame** commands, but the **.f** commands are shorter for convenience:

- **.f+** is the same as **.frame @\$frame + 1**.
- **.f-** is the same as **.frame @\$frame - 1**.

The dollar sign (\$) identifies the frame value as a [pseudo-register](#). The at sign (@) causes the debugger to access the value more quickly, because it notifies the debugger that a string is a register or pseudo-register.

When an application is running, the meaning of local variables depends on the location of the program counter, because the scope of such variables extends only to the function that they are defined in. Unless you use an **.f+** or **.f-** command (or a **.frame** command), the debugger uses the scope of the current function (the current frame on the stack) as the local context.

The *frame number* is the position of the stack frame within the stack trace. You can view this stack trace by using the **k, kb, kc, kd, kp, kP, kv (Display Stack Backtrace)** command or the [Calls window](#). The first line (the current frame) represents frame number 0. The subsequent lines represent frame numbers 1, 2, 3, and so on.

You can set the local context to a different stack frame to view new local variable information. However, the actual variables that are available depend on the code that is executed.

The debugger resets the local context to the scope of the program counter if any program execution occurs. The local context is reset to the top stack frame if the register context is changed.

[Send comments about this topic to Microsoft](#)

.fiber (Set Fiber Context)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.fiber** command specifies which fiber is used for the fiber context.

```
.fiber [Address]
```

Parameters

Address

Specifies the address of the fiber. If you omit this parameter or specify zero, the fiber context is reset to the current fiber.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about the process context, the register context, and the local context, see [Changing Contexts](#).

[Send comments about this topic to Microsoft](#)

.fiximports (Fix Target Module Imports)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.fiximports** command validates and corrects all static import links for a target module.

.fiximports Module

Parameters

Module

Specifies the target module whose imports the debugger corrects. *Module* can contain a variety of wildcard characters and specifiers. For more information about the syntax, see [String Wildcard Syntax](#). If you want to include spaces in *Module*, you must enclose the parameter in quotation marks.

Environment

Modes	User mode, kernel mode
Targets	Crash dump only (minidump only)
Platforms	All

Remarks

You can use the **.fiximports** command only when the target is a minidump that does not contain its own executable images.

When the debugger maps images for use as memory, the debugger does not automatically connect image imports to exporters. Therefore, instructions that refer to imports are disassembled in the same manner as in a live debugging session. You can use **.fiximports** to request that the debugger perform the appropriate import linking.

[Send comments about this topic to Microsoft](#)

.flash_on_break (Flash on Break)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.flash_on_break** command specifies whether the WinDbg taskbar entry flashes when WinDbg is minimized and the target breaks.

```
.flash_on_break on
.flash_on_break off
.flash_on_break
```

Parameters

on

Causes the WinDbg taskbar entry to flash if WinDbg is minimized and the target breaks into the debugger. This is the default behavior for WinDbg.

off

Prevents the WinDbg taskbar entry from flashing.

Environment

The **.flash_on_break** command is available only in WinDbg. You cannot use this command in script files.

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

If you use the **.flash_on_break** command without parameters, the debugger displays the current flash setting.

[Send comments about this topic to Microsoft](#)

.fnent (Display Function Data)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.fnent** command displays information about the function table entry for a specified function.

```
.fnent Address
```

Parameters

Address

Specifies the address of the function.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The symbol search algorithm for the **.fnent** command is the same as that of the [In \(List Nearest Symbols\)](#) command. The display first shows the nearest symbols. Then, the debugger displays the function entry for the first of these symbols.

If the nearest symbol is not in the function table, no information is displayed.

The following example shows a possible display.

```
0:001> .fnent 77f9f9e7
Debugger function entry 00b61f50 for:
(77f9f9e7)  ntdll!RtlpBreakWithStatusInstruction  |  (77f9fa98)  ntdll!DbgPrintReturnControlC

Params:    1
Locals:    0
Registers: 0

0:001> .fnent 77f9fa98
Debugger function entry 00b61f70 for:
(77f9fa98)  ntdll!DbgPrintReturnControlC  |  (77f9fb21)  ntdll!DbgPrompt

Non-FPO

0:001> .fnent 01005a60
No function entry for 01005a60
```

[Send comments about this topic to Microsoft](#)

.fnret (Display Function Return Value)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.fnret** command displays information about a function's return value.

```
.fnret [/s] Address [Value]
```

Parameters

/s

Sets the **\$callret** pseudo-register equal to the return value that is being displayed, including type information.

Address

Specifies the address of the function.

Value

Specifies the return value to display. If you include *Value*, **.fnret** casts *Value* to the return type of the specified function and displays it in the format of the return type. If you omit *Value*, the debugger obtains the return value of the function from the return value registers.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

If you include the *Value* parameter, the **.fnret** command only casts this value to the proper type and displays the results.

If you omit *Value*, the debugger uses the return value registers to determine this value. If a function has returned more recently than the function that the *Address* parameter specifies, the value that is displayed will probably not be a value that this function returned.

[Send comments about this topic to Microsoft](#)

.force_radix_output (Use Radix for Integers)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.force_radix_output** command specifies whether integers are displayed in decimal format or in the default radix.

```
.force_radix_output 0
.force_radix_output 1
```

Parameters

0

Displays all integers (except for long integers) in decimal format. This is the default behavior for the Debugger.

1

Displays all integers (except for long integers) in the default radix.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.force_radix_output** command affects the output of the [dt \(Display Type\)](#) command.

In WinDbg, **.force_radix_output** also affects the display in the [Locals window](#) and the [Watch window](#). You can select or clear **Always display numbers in default radix** on the shortcut menu of the Locals or Watch window to have the same effect as **.force_radix_output**. These windows are automatically updated after you issue this command.

The **.force_radix_output** command affects only the display of standard integers. To specify whether long integers are displayed in decimal format or the default radix, use the [.enable_long_status \(Enable Long Integer Display\)](#) command.

To change the default radix, use the [n \(Set Number Base\)](#) command.

[Send comments about this topic to Microsoft](#)

.force_tb (Forcibly Allow Branch Tracing)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.force_tb** command forces the processor to trace branches early in the boot process.

```
.force_tb
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

Typically, branch tracing is enabled after the debugger initializes the processor control block (PRCB). This initialization occurs early in the boot process.

However, if you have to use the **tb (Trace to Next Branch)** command before this initialization, you can use the **.force_tb** command to enable branch tracing earlier. Use this command carefully because it can corrupt your processor state.

[Send comments about this topic to Microsoft](#)

.formats (Show Number Formats)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.formats** command evaluates an expression or symbol in the context of the current thread and process and displays it in multiple numeric formats.

```
.formats expression
```

Parameters

expression

Specifies the expression to evaluate. For more information about the syntax, see [Numerical Expression Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The evaluated expression is displayed in hexadecimal, decimal, octal, and binary formats, as well as single-precision and double-precision floating-point format. ASCII character formats are also displayed when the bytes correspond to standard ASCII characters. The expression is also interpreted as a time stamp if it is in the allowed range.

The following example shows a **.formats** command.

```
0:000> .formats 1c407e62
Evaluate expression:
Hex: 1c407e62
Decimal: 473988706
Octal: 03420077142
Binary: 00011100 01000000 01111110 01100010
Chars: .@~b
Time: Mon Jan 07 15:31:46 1985
Float: low 6.36908e-022 high 0
Double: 2.34182e-315
```

The **Time** field displays a 32-bit value in CRT time stamp format and displays a 64-bit value in FILETIME format. You can distinguish these formats because the FILETIME format includes milliseconds and the CRT format does not.

.fpo (Control FPO Overrides)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.fpo** command controls the frame pointer omission (FPO) overrides.

```
.fpo -s [-fFlag] Address
.fpo -d Address
.fpo -x Address
.fpo -o Address
.fpo Address
```

Parameters

-s

Sets an FPO override at the specified address.

-fFlag

Specifies FPO flags for the override. You must not add a space between **-f** and *Flag*. If the flag takes an argument, you must add a space between the flag and that argument. If you want multiple flags, you must repeat the **-f** switch (for example, **-fb -fp 4 -fe**). You can use the **-f** switch only with **-s**. You can use one of the following values for *Flag*.

FLAG	EFFECT
b	Sets fUseBP equal to TRUE .
e	Sets fUseSEH equal to TRUE .
n	Sets cbFrame equal to FRAME_NONFPO . (By default, cbFrame is set to FRAME_FPO .)
l <i>Term</i>	Sets cdwLocals equal to <i>Term</i> . <i>Term</i> should specify the local DWORD count that you want.
p <i>Term</i>	Sets cdwParams equal to <i>Term</i> . <i>Term</i> should specify the parameter DWORD count that you want.
r <i>Term</i>	Sets cbRegs equal to <i>Term</i> . <i>Term</i> should specify the register count that you want.
s <i>Term</i>	Sets cbProcSize equal to <i>Term</i> . <i>Term</i> should specify the procedure size that you want.

FLAG	EFFECT
t <i>Term</i>	Sets cbFrame equal to <i>Term</i> . <i>Term</i> should specify one of the following frame types: <ul style="list-style-type: none"> • FRAME_FPO 0 • FRAME_TRAP 1 • FRAME_TSS 2 • FRAME_NONFPO 3

Address

Specifies the address where the debugger sets or removes the override or the address whose overrides the debugger should display. This address must be within a module in the current module list.

-d

Removes the FPO overrides at the specified address.

-x

Removes all FPO overrides within the module that contains the *Address* address.

-o

Displays all FPO overrides within the module that contains the *Address* address.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	all

Remarks

Without parameters, the **.fpo** command displays the FPO overrides for the specified address.

Some compilers (including Microsoft Visual Studio 6.0 and earlier versions) generate FPO information to indicate how the stack frame is set up. During stack walking, the debugger uses these FPO records to understand the stack. If the compiler generated incorrect FPO information, you can use the **.fpo** command to fix this problem.

[Send comments about this topic to Microsoft](#)

.frame (Set Local Context)

5/31/2017 • 3 min to read • [Edit Online](#)

The **.frame** command specifies which local context (scope) is used to interpret local variables or displays the current local context.

```
.frame [/c] [/r] [FrameNumber]
.frame [/c] [/r] = BasePtr [FrameIncrement]
.frame [/c] [/r] = BasePtr StackPtr InstructionPtr
```

Parameters

/c

Sets the specified frame as the current local override context. This action allows a user to access the nonvolatile registers for any function in the call stack.

/r

Displays registers and other information about the specified local context.

FrameNumber

Specifies the number of the frame whose local context you want. If this parameter is zero, the command specifies the current frame. If you omit this parameter, this command displays the current local context.

BasePtr

Specifies the base pointer for the stack trace that is used to determine the frame, if you add an equal sign (=) after the command name (**.frame**). On an x86-based processor, you add another argument after *BasePtr* (which is interpreted as *FrameIncrement*) or two more arguments after *BasePtr* (which are interpreted as *InstructionPtr* and *StackPtr*).

FrameIncrement

(x86-based processor only)

Specifies an additional quantity of frames past the base pointer. For example, if the base pointer 0x0012FF00 is the address of frame 3, the command **.frame 12ff00** is equivalent to **.frame 3**, and **.frame 12ff00 2** is equivalent to **.frame 5**.

StackPtr

(x86-based processor only) Specifies the stack pointer for the stack trace that is used to determine the frame. If you omit *StackPtr* and *InstructionPtr*, the debugger uses the stack pointer that the **esp** register specifies and the instruction pointer that the **eip** register specifies.

InstructionPtr

(x86-based processor only) Specifies the instruction pointer for the stack trace that is used to determine the frame. If you omit *StackPtr* and *InstructionPtr*, the debugger uses the stack pointer that the **esp** register specifies and the instruction pointer that the **eip** register specifies.

Environment

Modes	User mode, kernel mode
-------	------------------------

Targets	Live, crash dump
Platforms	All

Additional Information

For more information about the local context and other context settings, see [Changing Contexts](#). For more information about how to display local variables and other memory-related commands, see [Reading and Writing Memory](#).

Remarks

When an application is running, the meaning of local variables depends on the location of the program counter, because the scope of such variables extends only to the function that they are defined in. If you do not use the **.frame** command, the debugger uses the scope of the current function (the current frame on the stack) as the [local context](#).

To change the local context, use the **.frame** command and specify the frame number that you want.

The *frame number* is the position of the stack frame within the stack trace. You can view this stack trace with the **k (Display Stack Backtrace)** command or the [Calls window](#). The first line (the current frame) is frame number 0. The subsequent lines represent frame numbers 1, 2, 3, and so on.

If you use the **n** parameter with the **k** command, the **k** command displays frame numbers together with the stack trace. These frame numbers are always displayed in hexadecimal form. On the other hand, the **.frame** command interprets its argument in the default radix, unless you override this setting with a prefix such as `0x`. To change the default radix, use the **n (Set Number Base)** command.

You can set the local context to a different stack frame to enable you to view new local variable information. However, the actual variables that are available depend on the code that is being executed.

The local context is reset to the scope of the program counter if any application execution occurs. The local context is reset to the top stack frame if the register context is changed.

[Send comments about this topic to Microsoft](#)

.help (Meta-Command Help)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.help** command displays a list of all meta-commands.

```
.help
.help /D
```

Parameters

/D

Displays output using [Debugger Markup Language](#). The output contains a list of links that you can click to see the meta-commands that begin with a particular letter.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

For more information about meta-commands, use the **.help** command. For more information about standard commands, use the **?** command. For more information about extension commands, use the **!help** extension.

[Send comments about this topic to Microsoft](#)

.hh (Open HTML Help File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.hh** command opens the Debugging Tools for Windows documentation.

```
.hh [Text]
```

Parameters

Text

Specifies the text to find in the index of the Help documentation.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

You cannot use this command when you are performing [remote debugging through Remote.exe](#).

Additional Information

For more information about the Help documentation, see [Using the Help File](#).

Remarks

The **.hh** command opens the Debugging Tools for Windows documentation (Debugger.chm). If you specify *Text*, the debugger opens the **Index** pane in the documentation and searches for *Text* as a keyword in the index. If you do not specify *Text*, the debugger opens the **Contents** pane of the documentation.

[Send comments about this topic to Microsoft](#)

.hideinjectedcode (Hide Injected Code)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.hideinjectedcode** command turns on, or off, the hiding of injected code.

```
.hideinjectedcode { on | off }
.hideinjectedcode help
.hideinjectedcode
```

Parameters

on

Turns on the hiding of injected code.

off ****

Turns off the hiding of injected code

help

Displays help for this command.

Remarks

If you enter this command with no parameter, it displays help for the command.

[Send comments about this topic to Microsoft](#)

.holdmem (Hold and Compare Memory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.holdmem** command saves memory ranges and compares them to other memory ranges.

```
.holdmem -a Range
.holdmem -d { Range | Address }
.holdmem -D
.holdmem -o
.holdmem -c Range
```

Parameters

-a **** *Range*

Specifies the memory range to save. For more information about the syntax, see [Address and Address Range Syntax](#).

-d **** { *Range* | *Address* }

Specifies memory ranges to delete. If you specify *Address*, the debugger deletes any saved range that contains that address. If you specify *Range*, the debugger deletes any saved range that overlaps with *Range*. For more information about the syntax, see [Address and Address Range Syntax](#).

-D

Deletes all saved memory ranges.

-o

Displays all saved memory ranges.

-c *Range*

Compares the specified range to all saved memory ranges. For more information about the syntax, see [Address and Address Range Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how to manipulate memory and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

The **.holdmem** command compares memory ranges byte-for-byte.

If any of the specified memory locations do not exist in the virtual address space, the command returns an error.

[Send comments about this topic to Microsoft](#)

.idle_cmd (Set Idle Command)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.idle_cmd** command sets the *idle command*. This is a command that is executed whenever control returns from the target to the debugger. For example, when the target reaches a breakpoint, this command executes.

```
.idle_cmd
.idle_cmd String
.idle_cmd /d
```

Parameters

String

Specifies the string to which the idle command should be set.

/d

Clears the idle command.

Environment

This command cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

When **.idle_cmd** is used with no parameters it displays the current idle command.

In WinDbg, idle commands are stored in workspaces.

Here is an example. The idle command is set to **r eax**. Then, because the debugger is already idle, this command immediately executes, displaying the **eax** register:

```
windbg> .idle_cmd r eax
Execute when idle: r eax
eax=003b0de8
```

[Send comments about this topic to Microsoft](#)

.ignore_missing_pages (Suppress Missing Page Errors)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.ignore_missing_pages** command suppresses the error messages when a Kernel Memory Dump has missing pages.

```
.ignore_missing_pages 0
.ignore_missing_pages 1
.ignore_missing_pages
```

Parameters

0

Displays all missing page errors while debugging a Kernel Memory Dump. This is the default behavior of the debugger.

1

Suppresses the display of missing page errors while debugging a Kernel Memory Dump.

Environment

Modes	Kernel mode only
Targets	Dump file debugging only
Platforms	All

Additional Information

For more information about how to debug these dump files, see [Kernel Memory Dump](#).

Remarks

Without parameters, **.ignore_missing_pages** displays the current status of this setting.

[Send comments about this topic to Microsoft](#)

.inline (Toggle Inline Function Debugging)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.inline** command enables or disables inline function debugging.

```
.inline 0
.inline 1
```

Parameters

0

Disables inline function debugging.

1

Enables inline function debugging.

See also

[Debugging Optimized Code and Inline Functions](#)

[Send comments about this topic to Microsoft](#)

.imgscan (Find Image Headers)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.imgscan** command scans virtual memory for image headers.

```
.imgscan [Options]
```

Parameters

Options

Any of the following options:

/r **** Range

Specifies the range to search. For more information about the syntax, see [Address and Address Range Syntax](#). If you specify only one address, the debugger searches a range that begins at that address and extends 0x10000 bytes.

/I

Loads module information for any image header that is found.

/v

Displays verbose information.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

If you do not use the **/r** parameter, the debugger searches all virtual memory regions.

The **.imgscan** command displays any image headers that it finds and the header type. Header types include Portable Executable (PE) headers and Microsoft MS-DOS MZ headers.

The following example shows the **.imgscan** command.

```
0:000> .imgscan
MZ at 00400000, prot 00000002, type 01000000 - size 2d000
MZ at 77f80000, prot 00000002, type 01000000 - size 7d000
  Name: ntdll.dll
MZ at 7c570000, prot 00000002, type 01000000 - size b8000
  Name: KERNEL32.dll
```

[Send comments about this topic to Microsoft](#)

.jdinfo (Use JIT_DEBUG_INFO)

5/31/2017 • 4 min to read • [Edit Online](#)

The **.jdinfo** command uses a JIT_DEBUG_INFO structure as the source of the exception and context for just in time (JIT) debugging. The address to the structure is passed to the **.jdinfo** command using the %p parameter that is specified in the AeDebug registry entry.

For more information about the registry keys used, see [Enabling Postmortem Debugging](#). For more information about register contexts, see [Changing Contexts](#).

```
.jdinfo Address
```

Parameters

Address

Specifies the address of the JIT_DEBUG_INFO structure. The address to the structure is passed to the **.jdinfo** command using the %p parameter that is specified in the AeDebug registry entry.

Environment

Modes	User mode
Targets	Live, crash dump
Platforms	All

Example

This example show how the AeDebug registry entry can be configured to use the WinDbg can be used as the JIT debugger.

```
Debugger = "Path\WinDbg.EXE -p %ld -e %ld -c ".jdinfo 0x%p"
```

Then, when a crash occurs, the configured JIT debugger is invoked and the %p parameter is used to pass the address of the JIT_DEBUG_INFO structure to the **.jdinfo** command that is executed after the debugger is started.

```

```

Remarks

The **.jdinfo** command uses the **AeDebug** registry information introduced in Windows Vista. For more information about the registry keys used, see [Enabling Postmortem Debugging](#). The **.jdinfo** command takes the address of a **JIT_DEBUG_INFO** that the system set up for **AeDebug** and sets the context to the exception that caused the crash.

You can use the **.jdinfo** command instead of **-g** in **AeDebug** to have your debugger set to the **AeDebug** state without requiring execution.

This state can be advantageous, because under usual conditions, when a user-mode exception occurs, the following sequence occurs:

1. The Microsoft Windows operating system halts execution of the application.
2. The postmortem debugger is started.
3. The debugger attaches to the application.
4. The debugger issues a "Go" command. (This command is caused by the **-g** in the **AeDebug** key.)
5. The target attempts to execute and may or may not encounter the same exception.
6. This exception breaks into the debugger.

There are several problems that can occur because of these events:

- Exceptions do not always repeat, possibly because of a transient condition that no longer exists when the exception is restarted.
- Another event, such as a different exception, might occur. There is no way of knowing whether it is identical to the original event.
- Attaching a debugger involves injecting a new thread, which can be blocked if a thread is holding the loader lock. Injecting a new thread can be a significant disturbance of the process.

If you use **-c jdinfo** instead of **-g** in your **AeDebug** key, no execution occurs. Instead, the exception information is retrieved from the **JIT_DEBUG_INFO** structure using the **%p** variable.

For example, consider the following **AeDebug** key.

```
ntsd -p %ld -e %ld -c ".jdinfo 0x%p"
```

The following example is even less invasive. The **-pv** switch causes the debugger to attach noninvasively, which does not inject any new threads into the target.

```
ntsd -pv -p %ld -e %ld -c ".jdinfo 0x%p"
```

If you use this noninvasive option, exiting the debugger does not end the process. You can use the [.kill \(Kill Process\)](#) command to end the process.

If you want to use this for dump file debugging, you should use [.dump /j](#) to add the **JIT_DEBUG_INFO** structure to your dump file, when the dump file is created.

The **JIT_DEBUG_INFO** structure is defined as follows.

```
typedef struct _JIT_DEBUG_INFO {
    DWORD dwSize;
    DWORD dwProcessorArchitecture;
    DWORD dwThreadID;
    DWORD dwReserved0;
    ULONG64 lpExceptionAddress;
    ULONG64 lpExceptionRecord;
    ULONG64 lpContextRecord;
} JIT_DEBUG_INFO, *LPJIT_DEBUG_INFO;
```

You can use the **dt** command to display the **JIT_DEBUG_INFO** structure.

```
0: kd> dt JIT_DEBUG_INFO
nt!JIT_DEBUG_INFO
  +0x000 dwSize      : Uint4B
  +0x004 dwProcessorArchitecture : Uint4B
  +0x008 dwThreadID      : Uint4B
  +0x00c dwReserved0      : Uint4B
  +0x010 lpExceptionAddress : Uint8B
  +0x018 lpExceptionRecord : Uint8B
  +0x020 lpContextRecord  : Uint8B
```

Viewing the Exception Record, Call Stack and LastEvent Using WinDbg

After the **jdinfo** command has been used to set the context to the moment of failure, you can view the exception record returned by **jdinfo**, the call stack and the **lastevent**, as shown below, to investigate cause.

```
0:000> .jdinfo 0x00000000003E0000
----- Exception occurred on thread 0:15c8
ntdll!NtWaitForMultipleObjects+0x14:
00007ffc`81a959a4 c3          ret

----- Exception record at 00000000`003e0028:
ExceptionAddress: 00007ff791d81014 (CrashAV_x64!wmain+0x0000000000000014)
  ExceptionCode: c0000005 (Access violation)
  ExceptionFlags: 00000000
NumberParameters: 2

.kdfiles (Set Driver Replacement Map)

5/31/2017 • 2 min to read • [Edit Online](#)

The **.kdfiles** command reads a file and uses its contents as the driver replacement map.

```
.kdfiles MapFile
.kdfiles -m OldDriver NewDriver
.kdfiles -s SaveFile
.kdfiles -c
.kdfiles
```

Parameters

MapFile

Specifies the driver replacement map file to read.

-m

Adds a driver replacement association to the current association list.

OldDriver

Specifies the path and file name of the previous driver on the target computer. The syntax for *OldDriver* is the same as that of the first line after **map** in a driver replacement file. For more information about this syntax, see [Mapping Driver Files](#).

NewDriver

Specifies the path and file name of the new driver. This driver can be on the host computer or at some other network location. The syntax for *NewDriver* is the same as that of the second line after **map** in a driver replacement file. For more information about this syntax, see [Mapping Driver Files](#).

-s

Creates a file and writes the current driver replacement associations to that file.

SaveFile

Specifies the name of the file to create.

-c

Deletes the existing driver replacement map. (This option does not alter the map file itself. Instead, this option clears the debugger's current map settings.)

Environment

You can use the **.kdfiles** command in Microsoft Windows XP and later versions of Windows. If you use this command in earlier versions of Windows, the command has no effect and does not generate an error.

Modes	Kernel mode only
Targets	Live debugging only
Platforms	x86-based and Itanium-based processors only

Additional Information

For more information about and examples of driver replacement and the replacement of other kernel-mode modules, a description of the format for driver replacement map files, and restrictions for using this feature, see [Mapping Driver Files](#).

Remarks

If you use the **.kdfiles** command without parameters, the debugger displays the path and name of the current driver replacement map file and the current set of replacement associations.

When you run this command, the specified *MapFile* file is read. If the file is not found or if it does not contain text in the proper format, the debugger displays a message that states, "Unable to load file associations".

If the specified file is in the correct driver replacement map file format, the debugger loads the file's contents and uses them as the driver replacement map. This map remains until you exit the debugger, or until you issue another **.kdfiles** command.

After the file has been read, the driver replacement map is not affected by subsequent changes to the file (unless these changes are followed by another **.kdfiles** command).

Requirements

Version	Supported in Windows XP and later versions of the Windows operating system.
---------	---

[Send comments about this topic to Microsoft](#)

.kdtargetmac (Display Target MAC Address)

5/31/2017 • 1 min to read • [Edit Online](#)

Display Target MAC Address

```
.kdtargetmac
```

Parameters

Environment

Modes	kernel mode only
Targets	live debugging only
Platforms	all

Additional Information

Use the .kdtargetmac command to display the MAC (media access control) address of the target system.

```
0: kd> .kdtargetmac
The target machine MAC address in open-device format is: XXXXXXXXXXXX
```

The .kdtargetmac command is available if KDNET is enabled on the target system. Use the BCDEdit command with the /dbgsettings option to display the configuration on the target system. A debugtype of *NET* indicates that KDNET is configured.

```
C:\WINDOWS\system32>bcdedit /dbgsettings
key          1.2.3.4
debugtype    NET
hostip       192.168.1.10
port         50000
dhcp         Yes
The operation completed successfully.
```

For more information, see [Setting Up Kernel-Mode Debugging over a Network Cable Manually](#).

Remarks

Knowing the MAC address of the target system can be useful for network tracing and other utilities.

[Send comments about this topic to Microsoft](#)

.kframes (Set Stack Length)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.kframes** command sets the default length of a stack trace display.

```
.kframes FrameCountDefault
```

Parameters

FrameCountDefault

Specifies the number of stack frames to display when a stack trace command is used.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

You can use the **.kframes** command to set the default length of a stack trace display. This length controls the number of frames that the **k**, **kb**, **kp**, **kP**, and **kv** commands display and the number of DWORD_PTRs that the **kd** command displays.

You can override this default length by using the *FrameCount* or *WordCount* parameters for these commands.

If you never issue the **.kframes** command, the default count is 20 (0x14).

[k, kb, kc, kd, kp, kP, kv \(Display Stack Backtrace\)](#)

[Send comments about this topic to Microsoft](#)

.kill (Kill Process)

5/31/2017 • 2 min to read • [Edit Online](#)

In user mode, the **.kill** command ends a process that is being debugged.

In kernel mode, the **.kill** command ends a process on the target computer.

User-Mode Syntax

```
.kill [ /h | /n ]
```

Kernel-Mode Syntax

```
.kill Process
```

Parameters

/h

(User mode only) Any outstanding debug event will be continued and marked as handled. This is the default.

/n

(User mode only) Any outstanding debug event will be continued without being marked as handled.

Process

Specifies the address of the process to be terminated. If *Process* is omitted or zero, the default process for the current system state will be terminated.

Environment

In kernel mode, this command is supported on Microsoft Windows Server 2003 and later versions of Windows.

Modes	user mode, kernel mode
Targets	live debugging only
Platforms	all

Remarks

In user mode, this command ends a process that is being debugged. If the debugger is attached to a child process, you can use **.kill** to end the child process without ending the parent process. For more information, see Examples.

In kernel mode, this command schedules the selected process on the target computer for termination. The next time that the target can run (for example, by using a **g (Go)** command), the specified process is ended.

You cannot use this command during local kernel debugging.

Examples

Using .childdbg

Suppose you attach a debugger to parent process (Parent.exe) before it creates a child process. You can enter the command **.childdbg 1** to tell the debugger to attach to any child process that the parent creates.

```
1:001> .childdbg 1
Processes created by the current process will be debugged
```

Now let the parent process run, and break in after it has created the child process. Use the **| (Process Status)** command to see the process numbers for the parent and child processes.

```
0:002> /*
. 0    id: 7f8 attach  name: C:\Parent\x64\Debug\Parent.exe
1    id: 2d4 child    name: notepad.exe
```

In the preceding output, the number of the child process (notepad.exe) is 1. The dot (.) at the beginning of the first line tells us that the parent process is the current process. To make the child process the current process, enter **|1s**.

```
0:002> |1s
...
1:001> /*
# 0    id: 7f8 attach  name: C:\Parent\x64\Debug\Parent.exe
. 1    id: 2d4 child    name: notepad.exe
```

To kill the child process, enter the command **.kill**. The parent process continues to run.

```
1:001> .kill
Terminated.  Exit thread and process events will occur.
1:001> g
```

Using the -o parameter

When you start WinDbg or CDB, you can use the **-o** parameter to tell the debugger that it should attach to child processes. For example, the following command starts WinDbg, which starts and attaches to Parent.exe. When Parent.exe creates a child process, WinDbg attaches to the child process.

windbg -g -G -o Parent.exe

For more information, see [WinDbg Command-Line Options](#) and [CDB Command-Line Options](#).

Requirements

Version	Versions:(Kernel mode) Supported in Windows Server 2003 and later.
---------	--

[Send comments about this topic to Microsoft](#)

.lastevent (Display Last Event)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.lastevent** command displays the most recent exception or event that occurred.

```
.lastevent
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about exceptions and events, see [Controlling Exceptions and Events](#).

Remarks

Breaking into the debugger always creates an exception. There is always a *last event* when the debugger accepted command input. If you break into the debugger by using **CTRL+C**, **CTRL+BREAK**, or Debug | Break, an exception code of 0x80000003 is created.

[Send comments about this topic to Microsoft](#)

.lines (Toggle Source Line Support)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.lines** command enables or disables support for source-line information.

```
.lines [-e|-d|-t]
```

Parameters

-e

Enables source line support.

-d

Disables source line support.

-t

Turns source line support on or off. If you do not specify parameters for **.lines**, the default behavior of the **.lines** command is this switching of source line support.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about source debugging and related commands, see [Debugging in Source Mode](#).

Remarks

You must enable source line support before you can perform source-level debugging. This support enables the debugger to load source line symbols.

You can enable source line support by using the **.lines** command or the [-lines command-line option](#). If source line support is already enabled, using the **.lines** command disables this support.

By default, if you do not use the **.lines** command, WinDbg turns on source line support, and console debuggers (KD, CDB, NTSD) turn off the support. For more information about how to change this setting, see [Setting Symbol Options](#).

[Send comments about this topic to Microsoft](#)

.load, .loadby (Load Extension DLL)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.load** and **.loadby** commands load a new extension DLL into the debugger.

```
.load DLLName
!DLLName.load
.loadby DLLName ModuleName
```

Parameters

DLLName

Specifies the debugger extension DLL to load. If you use the **.load** command, *DLLName* should include the full path. If you use the **.loadby** command, *DLLName* should include only the file name.

ModuleName

Specifies the module name of a module that is located in the same directory as the extension DLL that *DLLName* specifies.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how to load, unload, and control extensions, see [Loading Debugger Extension DLLs](#).

Remarks

When you use the **.load** command, you must specify the full path.

When you use the **.loadby** command, you do not specify the path. Instead, the debugger finds the module that the *ModuleName* parameter specifies, determines the path of that module, and then uses that path when the debugger loads the extension DLL. If the debugger cannot find the module or if it cannot find the extension DLL, you receive an error message that specifies the problem. There does not have to be any relationship between the specified module and the extension DLL. Using the **.loadby** command is therefore simply a way to avoid typing a long path.

After the **.load** or **.loadby** command has been completed, you can access the commands that are stored in the loaded extension.

To load an extension DLL, you can do one of the following:

- Use the **.load** or **.loadby** command.
- Execute an extension by issuing the full *!DLLName.ExtensionCommand* syntax. If the debugger has not

yet loaded *DLLName.dll*, it loads the DLL at this point.

[Send comments about this topic to Microsoft](#)

.locale (Set Locale)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.locale** command sets the locale or displays the current locale.

```
.locale [Locale]
```

Parameters

Locale

Specifies the locale that you want. If you omit this parameter, the debugger displays the current locale.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about locale, see the **setlocale** routine in the MSDN Library.

Remarks

The locale controls how Unicode strings are displayed.

The following examples show the **.locale** command.

```
kd> .locale
Locale: C

kd> .locale E
Locale: English_United States.1252

kd> .locale c
Locale: Catalan_Spain.1252

kd> .locale C
Locale: C
```

[Send comments about this topic to Microsoft](#)

.logappend (Append Log File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.logappend** command appends a copy of the events and commands from the [Debugger Command window](#) to the specified log file.

```
.logappend [/u] [FileName]
```

Parameters

/u

Writes the log file in Unicode format. If you omit this parameter, the debugger writes the log file in ASCII (ANSI) format.

Note When you are appending to an existing log file, you should use the **/u** parameter only if you created the log file by using the **/u** option. Otherwise, your log file will contain ASCII and Unicode characters, which might make it more difficult to read.

FileName

Specifies the name of the log file. You can specify a full path or only the file name. If the file name contains spaces, enclose *FileName* in quotation marks. If you do not specify the path, the debugger uses the current directory. If you omit *FileName*, the debugger names the file Dbgeng.log.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

If you already have a log file open when you run the **.logappend** command, the debugger closes the log file. If you specify the name of a file that already exists, the debugger appends new information to the file. If the file does not exist, the debugger creates it.

[Send comments about this topic to Microsoft](#)

.logclose (Close Log File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.logclose** command closes any open log file.

```
.logclose
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

[Send comments about this topic to Microsoft](#)

.logfile (Display Log File Status)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.logfile** command determines whether a log file exists and displays the file's status.

```
.logfile
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

[Send comments about this topic to Microsoft](#)

.logopen (Open Log File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.logopen** command sends a copy of the events and commands from the [Debugger Command window](#) to a new log file.

```
.logopen [Options] [FileName]  
.logopen /d
```

Parameters

Options

Any of the following options:

/t

Appends the process ID with the current date and time to the log file name. This data is inserted after the file name and before the file name extension.

/u

Writes the log file in Unicode format. If you omit this option, the debugger writes the log file in ASCII (ANSI) format.

FileName

Specifies the name of the log file. You can specify a full path or only the file name. If the file name contains spaces, enclose *FileName* in quotation marks. If you do not specify a path, the debugger uses the current directory. If you omit *FileName*, the debugger names the file Dbgeng.log.

/d

Automatically chooses a file name based on the name of the target process or target computer and the state of the target. The file always has the .log file name extension.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

If you already have a log file open when you run the **.logopen** command, the debugger closes it. If you specify a file name that already exists, the file's contents are overwritten.

The **.logopen /t** command appends the process ID, date, and time to the log file name. In the following example, the process ID in hexadecimal is 0x02BC, the date is February 28, 2005, and the time is 9:05:50.935.

```
0:000> .logopen /t c:\logs\myfile.txt
Opened log file 'c:\logs\myfile_02BC_2005-02-28_09-05-50-935.txt'
```

[Send comments about this topic to Microsoft](#)

.netsyms (Disable Network Symbol Loading)

5/26/2017 • 1 min to read • [Edit Online](#)

Use the .netsyms command to allow or disallow loading symbols from a network path.

Syntax

.netsyms {yes|no}

Parameters

yes

Enables network symbol loading. This is the default.

no

Disables network symbol loading.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

Use .netsyms with no argument to display the current state of this setting.

Use **!sym noisy** or the **-n WinDbg Command-Line Option** to display additional detail as symbols are loaded.

[Send comments about this topic to Microsoft](#)

.netuse (Control Network Connections)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.netuse** command adds a connection to a network share.

```
.netuse /a "[Local]" "Remote" "[User]" "[Password]"
```

Parameters

/a

Adds a new connection. You must always use the **/a** switch.

Local

Specifies the drive letter to use for the connection. You must enclose *Local* in quotation marks. If you omit this parameter, you must include an empty pair of quotation marks as the parameter.

Remote

Specifies the UNC path of the share that is being connected. You must enclose *Remote* in quotation marks.

User

Specifies the user name of an account that is authorized to establish the connection. You must enclose *User* in quotation marks. If you omit this parameter, you must include an empty pair of quotation marks as the parameter.

Password

Specifies the password that is associated with the *User* account. You must enclose *Password* in quotation marks. If you omit this parameter, you must include an empty pair of quotation marks as the parameter.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The **.netuse** command behaves like the **net use** Microsoft MS-DOS command.

If you use **.netuse** during a remote debugging session, this command affects the debugging server, not the debugging client.

The following example shows this command.

```
0:000> .netuse "m:" "\myserver\myshare" "" ""
```

[Send comments about this topic to Microsoft](#)

.noshell (Prohibit Shell Commands)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.noshell** command prevents you from using **.shell** commands.

```
.noshell
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about the command shell and for other ways to disable shell commands, see [Using Shell Commands](#).

Remarks

If you use the **.noshell** command, you cannot use **.shell (Command Shell)** commands as long as the debugger is running, even if you start a new debugging session.

If you are performing remote debugging, this command is useful for security purposes.

[Send comments about this topic to Microsoft](#)

.noverversion (Disable Version Checking)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.noverversion** command disables all version checking of extension DLLs.

```
.noverversion
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The build number of extension DLLs should match the build number of the computer that you are debugging, because the DLLs are compiled and linked with dependencies on specific versions of data structures. If the versions do not match, you typically receive the following message.

```
*** Extension DLL(1367 Free) does not match target system(1552 Free)
```

[Send comments about this topic to Microsoft](#)

.ocommand (Expect Commands from Target)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.ocommand** command enables the target application to send commands to the debugger.

```
.ocommand String
.ocommand -d
.ocommand
```

Parameters

String

Specifies the command prefix string. *String* can include spaces, but you cannot use C-style control characters such as `\"` and `\n`. You can also enclose *String* in quotation marks. However, if *String* includes a semicolon, leading spaces, or trailing spaces, you must enclose *String* in quotation marks.

-d

Deletes the command prefix string.

Environment

Modes	User mode only
Targets	Live debugging only
Platforms	All

Additional Information

For more information about [OutputDebugString](#) and other user-mode functions that communicate with a debugger, see the Microsoft Windows SDK documentation.

Remarks

If you use the **.ocommand** command without parameters, the debugger displays the current command prefix string. To clear the existing string, use **.ocommand -d**.

When you have set a command prefix string, any target output (such as the contents of an [OutputDebugString](#) command) is scanned. If this output begins with the command prefix string, the text of the output that follows the prefix string is treated as a debugger command string and is run. When this text is executed, the command string is not displayed.

The target can include an [.echo \(Echo Comment\)](#) command in the output string if you want additional messages. Target output that does not begin with the prefix string is displayed in the typical manner.

After the commands within the command string have been executed, the target remains broken into the debugger, unless the final command is [g \(Go\)](#).

The comparison between the command prefix string and the target output is not case sensitive. (However, subsequent uses of **.ocommand** display the string that you entered with the case preserved).

For this example, assume that you enter the following command in the debugger.

```
0:000> .ocommand magiccommand
```

Then, the target application executes the following line.

```
OutputDebugString("MagicCommand kb;g");
```

The debugger recognizes the command string prefix and executes **kb;g** immediately.

However, the following line does not cause any commands to be executed.

```
OutputDebugString("Command on next line.\nmagiccommand kb;g");
```

There are no commands executed from the preceding example because the command string prefix is not at the beginning of the output, even though it does begin a new line.

Note You should choose a command string prefix that will not likely appear in any target output other than your own commands.

[Send comments about this topic to Microsoft](#)

.nvload (NatVis Load)

5/31/2017 • 1 min to read • [Edit Online](#)

The .nvload command loads a NatVis file into the debugger environment. After the visualization is loaded, it will be used to render data defined in the visualization.

```
.nvload FileName|ModuleName
```

Parameters

FileName | ModuleName

Specifies the NatVis file name or module name to load.

The **FileName** is the explicit name of a .natvis file to load. A fully qualified path can be used.

The **ModuleName** is the name of a module in the target process being debugged. All NatVis files which are embedded within the symbol file (PDB) of the named module name are loaded, if there are any available.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information, see [Writing debugger type visualizers for C++ using .natvis files](#).

See also

[dx \(Display NatVis Expression\)](#)

[Send comments about this topic to Microsoft](#)

.nvlist (NatVis List)

5/31/2017 • 1 min to read • [Edit Online](#)

The `.nvlist` command lists the NatVis files loaded into the debugger environment.

```
.nvlist
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information, see [Writing debugger type visualizers for C++ using .natvis files](#).

See also

[dx \(Display NatVis Expression\)](#)

[Send comments about this topic to Microsoft](#)

.nvunload (NatVis Unload)

5/31/2017 • 1 min to read • [Edit Online](#)

The .nvunload command unloads a NatVis file from the debugger environment.

```
.nvunload FileName|ModuleName
```

FileName | ModuleName

Specifies the NatVis file name or module name to unload.

The **FileName** is the explicit name of a .natvis file to unload. A fully qualified path can be used.

The **ModuleName** is the name of a module in the target process being debugged. All NatVis files which are embedded within the symbol file (PDB) of the named module name are unloaded.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information, see [Writing debugger type visualizers for C++ using .natvis files](#).

See also

[dx \(Display NatVis Expression\)](#)

[Send comments about this topic to Microsoft](#)

.nvunloadall (NatVis Unload All)

5/31/2017 • 1 min to read • [Edit Online](#)

The .nvunloadall command unloads all of the NatVis files from the debugger environment.

```
.nvunloadall
```

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information, see [Writing debugger type visualizers for C++ using .natvis files](#).

See also

[dx \(Display NatVis Expression\)](#)

[Send comments about this topic to Microsoft](#)

.ofilter (Filter Target Output)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.ofilter** command filters the output from the target application or target computer.

```
.ofilter [/!] String
.ofilter ""
.ofilter
```

Parameters

!

Reverses the filter so that the debugger displays only output that does not contain *String*. If you do not use this parameter, the debugger displays only output that contains *String*.

String

Specifies the string to match in the target's output. *String* can include spaces, but you cannot use C-style control characters such as `\"` and `\n`. *String* might contain a variety of wildcard characters and specifiers. For more information about the syntax, see [String Wildcard Syntax](#).

You can enclose *String* in quotation marks. However, if *String* includes a semicolon, leading spaces, or trailing spaces, you must use quotation marks. Alphanumeric characters in *String* are converted to uppercase letters, but the actual pattern matching is case insensitive.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about [OutputDebugString](#) and other user-mode routines, see the Microsoft Windows SDK documentation. For more information about [DbgPrint](#), [DbgPrintEx](#), and other kernel-mode routines, see the Windows Driver Kit (WDK).

Remarks

If you use the **.ofilter** command without parameters, the debugger displays the current pattern-matching criteria.

To clear the existing filter, use **.ofilter ""**. This command filters any data that is sent by user-mode routines (such as [OutputDebugString](#)) and kernel-mode routines (such as [DbgPrint](#)). However, the debugger always displays prompts that [DbgPrompt](#) sends.

The [DbgPrintEx](#) and [KdPrintEx](#) routines supply another method of filtering debugging messages that you do not want.

[Send comments about this topic to Microsoft](#)

.open (Open Source File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.open** command searches the source path for a source file and opens this file.

```
.open [-m Address] FileName  
.open -a Address
```

Parameters

FileName

Specifies the source file name. This name can include an absolute or relative path. Unless you specify an absolute path, the path is interpreted as relative to a directory in the source path.

-m **** *Address*

Specifies an address within the source file. This address must be contained in a known module. You should use the **-m** **** *Address* parameter if the file that *FileName* specifies is not unique. For more information about the syntax, see [Address and Address Range Syntax](#).

The **-m** parameter is required if you are using a [source server](#) to retrieve the source files.

-a *Address*

Specifies an address within the source file. This address must be contained in a known module. If the debugger can find the source file, the debugger loads and opens the file, and the line that corresponds to the specified address is highlighted. If the debugger cannot find the source file, the address is displayed in the [Disassembly window](#). For more information about the syntax, see [Address and Address Range Syntax](#).

Environment

You can use the **.open** command only in WinDbg, and you cannot use it in script files.

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about source files and source paths and for other ways to load source files, see [Source Path](#).

[Send comments about this topic to Microsoft](#)

.opendump (Open Dump File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.opendump** command opens a dump file for debugging.

```
.opendump DumpFile
.opendump /c "DumpFileInArchive" [CabFile]
```

Parameters

DumpFile

Specifies the name of the dump file to open. *DumpFile* should include the file name extension (typically .dmp or .mdmp) and can include an absolute or relative path. Relative paths are relative to the directory that you started the debugger in.

/c "DumpFileInArchive"

Specifies the name of a dump file to debug. This dump file must be contained in the archive file that *CabFile* specifies. You must enclose the *DumpFileInArchive* file in quotation marks.

CabFile

Specifies the name of an archive file to open. *CabFile* should include the file name extension (typically .cab) and can include an absolute or relative path. Relative paths are relative to the directory that you started the debugger in. If you use the **/c** switch to specify a dump file in an archive but you omit *CabFile*, the debugger reuses the archive file that you most recently opened.

Environment

Modes	User mode, kernel mode
Targets	Crash dump only (but you can use this command if other sessions are running)
Platforms	All

Remarks

After you use the **.opendump** command, you must use the **g (Go)** command to finish loading the dump file.

When you are opening an archive file (such as a CAB file), you should use the **/c** switch. If you do not use this switch and you specify an archive for *DumpFile*, the debugger opens the first file that has an .mdmp or .dmp file name extension within this archive.

You can use **.opendump** even if a debugging session is already in progress. This feature enables you to debug more than one crash dump at the same time. For more information about how to control a multiple-target session, see [Debugging Multiple Targets](#).

[Send comments about this topic to Microsoft](#)

.outmask (Control Output Mask)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.outmask** command controls the current output mask.

```
.outmask[-] [/l] Expression
.outmask /a
.outmask /d
```

Parameters

Expression

Specifies the flags to add to the mask. *Expression* can be any ULONG value that specifies the flag bits that you want. For a list of the possible flags, see the table in the Remarks section.

- Removes the bits that *Expression* specifies from the mask, instead of adding them to the mask.

/l

Preserves the current value of the log file's output mask. If you do not include **/l**, the log file's output mask is the same as the regular output mask.

/a

Activates all mask flags. This parameter is equivalent to **.outmask 0xFFFFFFFF**.

/d

Restores the output mask to the default value. This parameter is equivalent to **.outmask 0x3F7**.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

Each output mask flag enables the debugger to display certain output in the [Debugger Command Window](#). If all of the mask flags are set, all output is displayed.

You should remove output mask flags with caution, because you might be unable to read debugger output.

The following flag values exist.

VALUE	DEFAULT SETTING	DESCRIPTION
1	On	Normal output

VALUE	DEFAULT SETTING	DESCRIPTION
2	On	Error output
4	On	Warnings
8	Off	Additional output
0x10	On	Prompt output
0x20	On	Register dump before prompt
0x40	On	Warnings that are specific to extension operation
0x80	On	Debug output from the target (for example, OutputDebugString or DbgPrint)
0x100	On	Debug input expected by the target (for example, DbgPrompt)
0x200	On	Symbol messages (for example, !sym noisy)

[Send comments about this topic to Microsoft](#)

.pagein (Page In Memory)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.pagein** command pages in the specified region of memory.

```
.pagein [Options] Address
```

Parameters

Options

Any of the following options:

/p **** Process

Specifies the address of the process that owns the memory that you want to page in. (More precisely, this parameter specifies the address of the EPROCESS block for the process.) If you omit *Process* or specify zero, the debugger uses the current process setting. For more information about the process setting, see [.process \(Set Process Context\)](#)

/f

Forces the memory to be paged in, even if the address is in kernel memory and the version of the Microsoft Windows operating system does not support this action.

Address

Specifies the address to page in.

Environment

Modes	Kernel mode only (but not during local kernel debugging)
Targets	Live debugging only
Platforms	All

Remarks

After you run the **.pagein** command, you must use the **g (Go)** command to resume program execution. After a brief time, the target computer automatically breaks into the debugger again.

At this point, the address that you specify is paged in. If you use the **/p** option, the process context is also set to the specified process, exactly as if you used the [.process /i Process](#) command.

If the address is already paged in, the **.pagein** command still checks that the address is paged in and then breaks back into the debugger. If the address is invalid, this command only breaks back into the debugger.

In Windows Server 2003 and Windows XP, you can page in only user-mode addresses by using **.pagein**. You can override this restriction by using the **/f** switch, but we do not recommend that you use this switch. In Windows Vista, you can safely page in user-mode and kernel-mode memory.

Warning If you use **.pagein** on an address in a kernel stack in Windows Server 2003 or Windows XP, a bug check

might occur.

Requirements

Version	Supported in Windows XP and later versions of Windows.
---------	--

[Send comments about this topic to Microsoft](#)

.pcmd (Set Prompt Command)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.pcmd** command causes the debugger to issue a command whenever the target stops executing and to display a prompt in the [Debugger Command window](#) with register or target state information.

```
.pcmd -s CommandString
.pcmd -c
.pcmd
```

Parameters

-s **** *CommandString*

Specifies a new prompt command string. Whenever the target stops executing, the debugger issues and immediately runs the *CommandString* command. If *CommandString* contains spaces or semicolons, you must enclose it in quotation marks.

-c

Deletes any existing prompt command string.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about the Debugger Command window prompt, see [Using Debugger Commands](#).

Remarks

If you use the **.pcmd** command without parameters, the current prompt command is displayed.

When you set a prompt command by using **.pcmd -s**, the specified *CommandString* is issued whenever the target stops executing (for example, when a **g**, **p**, or **t** command ends). The *CommandString* command is not issued when you use a non-execution command, unless that command displays registers or target state information.

In the following example, the first use of **.pcmd** sets a fixed string that appears with the prompt. The second use of **.pcmd** causes the debugger to display the target's current process ID and thread ID every time that the prompt appears. The special prompt does not appear after the **.ttime** command is used, because that command does not involve execution.

```
0:000> .pcmd
No per-prompt command

0:000> .pcmd -s ".echo Execution is done."
Per-prompt command is '.echo Execution is done.'

0:000> t
Prymes!isPrime+0xd0:
004016c0 837dc400      cmp dword ptr [ebp-0x3c],0x0 ss:0023:0012fe70=00000002
Execution is done.

0:000> t
Prymes!isPrime+0xd4:
004016c4 7507          jnz     Prymes!isPrime+0xdd (004016cd)
[br=1]
Execution is done.

0:000> .ttime
Created: Thu Aug 21 13:18:59 2003
Kernel: 0 days 0:00:00.031
User:   0 days 0:00:00.000

0:000> .pcmd -s "r $tpid, $tid"
Per-prompt command is 'r $tpid, $tid'

0:000> t
Prymes!isPrime+0xdd:
004016cd ebc0          jmp     Prymes!isPrime+0x9f (0040168f)
$tpid=0000080c $tid=00000514

0:000> t
Prymes!isPrime+0x9f:
0040168f 8b55fc          mov     edx,[ebp-0x4]      ss:0023:0012fea8=00000005
$tpid=0000080c $tid=00000514
```

[Send comments about this topic to Microsoft](#)

.pop (Restore Debugger State)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.pop** command restores the state of the debugger to a state that has previously been saved by using the **.push (Save Debugger State)** command.

```
.pop
.pop /r
.pop /r /q
```

Parameters

/r

Specifies that the saved values of the pseudo-registers \$t0 to \$t19 should be restored. If **/r** is not included, these values are not affected by the **.pop** command.

/q

Specifies that the command executes quietly. That is, the command executes without displaying any output.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

This command is most useful when used with [scripts](#) and [debugger command programs](#) so that they can work with one fixed state. If the command is successful, no output is displayed.

[Send comments about this topic to Microsoft](#)

.prefer_dml (Prefer Debugger Markup Language)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.prefer_dml** command sets the default behavior for commands that are capable of providing output in the Debugger Markup Language (DML) format.

```
.prefer_dml 0
.prefer_dml 1
```

Parameters

0

By default, all commands will provide plain text output.

1

By default, commands that are capable of providing DML output will provide DML output.

See also

[Debugger Markup Language Commands](#)

[Send comments about this topic to Microsoft](#)

.process (Set Process Context)

5/31/2017 • 4 min to read • [Edit Online](#)

The **.process** command specifies which process is used for the process context.

```
.process [/i] [/p [/r]] [/P] [Process]
```

Parameters

/i

(Windows XP and later; live debugging only; not during local kernel debugging) Specifies that *Process* is to be debugged *invasively*. This kind of debugging means that the operating system of the target computer actually makes the specified process active. (Without this option, the **.process** command alters the debugger's output but does not affect the target computer itself.) If you use **/i**, you must use the **g (Go)** command to execute the target. After several seconds, the target breaks back in to the debugger, and the specified *Process* is active and used for the process context.

/p

Translates all transition page table entries (PTEs) for this process to physical addresses before access, if you use **/p** and *Process* is nonzero. This translation might cause slowdowns, because the debugger must find the physical addresses for all of the memory that this process uses. Also, the debugger might have to transfer a significant amount of data across the debug cable. (This behavior is the same as **.cache forcedecodeuser**.)

If you include the **/p** option and *Process* is zero or you omit it, the translation is disabled. (This behavior is the same as **.cache noforcedecodeptes**.)

/r

Reloads user-mode symbols after the process context has been set, if you use the **/r** and **/p** options. (This behavior is the same as **.reload /user**.)

/P

(Live debugging and complete memory dumps only) Translates all transition page table entries (PTEs) to physical addresses before access, if you use **/P** and *Process* is nonzero. Unlike the **/p** option, the **/P** option translates the PTEs for all user-mode and kernel-mode processes, not only the specified process. This translation might cause slowdowns, because the debugger must find the physical addresses for all memory in use. Also, the debugger might have to transfer lots of data across the debug cable. (This behavior is the same as **.cache forcedecodeptes**.)

Process

Specifies the address of the process that you want. (More precisely, this parameter specifies the address of the EPROCESS block for this process). The process context is set to this process. If you omit *Process* or specify zero, the process context is reset to the default process for the current system state. (If you used the **/i** option to set process context, you must use the **/i** option to reset the process context.)

Environment

Modes	Kernel mode only
Targets	Live, crash dump

Additional Information

For more information about the process context and other context settings, see [Changing Contexts](#).

Remarks

Typically, when you are doing kernel debugging, the only visible user-mode address space is the one that is associated with the current process.

The **.process** command instructs the kernel debugger to use a specific user-mode process as the *process context*. This usage has several effects, but the most important is that the debugger has access to the virtual address space of this process. The debugger uses the page tables for this process to interpret all user-mode memory addresses, so you can read and write to this memory.

The **.context (Set User-Mode Address Context)** command has a similar effect. However, the **.context** command sets the *user-mode address context* to a specific page directory, while the **.process** command sets the process context to a specific process. On an x86-based processor, **.context** and **.process** have almost the same effect. However, on an Itanium-based processor, a single process might have more than one page directory. In this situation, the **.process** command is more powerful, because it enables access to all of the page directories that are associated with a process. For more information about the process context, see [Process Context](#).

Note If you are performing live debugging, you should use the **/i** or the **/p** parameter. Without one of these parameters, you cannot correctly display user-mode or session memory.

The **/i** parameter activates the target process. When you use this option, you must execute the target once for this command to take effect. If you execute again, the process context is lost.

The **/p** parameter enables the **forcedecodeuser** setting. (You do not have to use **/p** if the **forcedecodeuser** option is already active.) The process context and the **forcedecodeuser** state remain only until the target executes again.

If you are performing crash dump debugging, the **/i** and **/p** options are not available. However, you cannot access any part of the user-mode process' virtual address space that were paged to disk when the crash occurred.

If you want to use the kernel debugger to set breakpoints in user space, use the **/i** option to switch the target to the correct process context.

The following example shows how to use the **!process** extension to find the address of the EPROCESS block for the desired process.

```
kd> !process 0 0
**** NT ACTIVE PROCESS DUMP ****
PROCESS fe5039e0 SessionId: 0 Cid: 0008 Peb: 00000000 ParentCid: 0000
  DirBase: 00030000 ObjectTable: fe529b68 TableSize: 50.
  Image: System

.....
PROCESS fe3c0d60 SessionId: 0 Cid: 0208 Peb: 7ffdf000 ParentCid: 00d4
  DirBase: 0011f000 ObjectTable: fe3d0f48 TableSize: 30.
  Image: regsvc.exe
```

Now the example uses the **.process** command with this process address.

```
kd> .process fe3c0d60
Implicit process is now fe3c0d60
```

Notice that this command makes the **.context** command unnecessary. The user-mode address context already has the desired value.

```
kd> .context
User-mode page directory base is 11f000
```

This value enables you to examine the address space in various ways. For example, the following example shows the output of the **!peb** extension.

```
kd> !peb
PEB at 7FFDF000
  InheritedAddressSpace:  No
  ReadImageFileExecOptions: No
  BeingDebugged:          No
  ImageBaseAddress:        01000000
  Ldr.Initialized: Yes
  Ldr.InInitializationOrderModuleList: 71f40 . 77f68

    Environment: 0x10000
```

[Send comments about this topic to Microsoft](#)

.prompt_allow (Control Prompt Display)

5/31/2017 • 2 min to read • [Edit Online](#)

The **.prompt_allow** command controls what information is displayed during stepping and tracing and whenever the target's execution stops.

```
.prompt_allow {+|-}Item [...]
.prompt_allow
```

Parameters

+

Displays the specified item at the stepping, tracing, and execution prompt. You must add a space before the plus sign (+), but you cannot add a space after it.

-

Prevents the specified item from being displayed at the stepping, tracing, and execution prompt. You must add a space before the minus sign (-), but you cannot add a space after it.

Item

Specifies an item to display or not display. You can specify any number of items. Separate multiple items by spaces. You must add a plus sign (+) or minus sign (-) before each item. You can use the following items:

dis

The disassembled instructions at the current location.

ea

The effective address for the current instruction.

reg

The current state of the most important registers. You can disable register display by using the **pr**, **tr**, or **.prompt_allow -reg** command. All three of these commands control the same setting, and you can use any of them to override any previous use of these commands.

You can also disable register display by using the **l-os** command. This setting is separate from the other three commands, as described in the following Remarks section. To control which registers and flags are displayed, use the **rm (Register Mask)** command.

src

The source line that corresponds to the current instruction. You can disable source line display by using the **l-ls** or **.prompt_allow -src** commands. You must enable source line display through both mechanisms to be visible.

sym

The symbol for the current instruction. This symbol includes the current module, function name, and offset.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump

Additional Information

For more information about commands that affect execution, see [Controlling the Target](#).

Remarks

You can use the **.prompt_allow** command without parameters to show which items are displayed and are not displayed. Every time that you run **.prompt_allow**, the debugger changes the status of only the specified items.

By default, all items are displayed.

If you have used the **l+os** option, this option overrides any of the **.prompt_allow** options other than **src**.

You can also use a complex command such as the following example.

```
0:000> .prompt_allow -reg -dis +ea
Allow the following information to be displayed at the prompt:
(Other settings can affect whether the information is actually displayed)
    sym - Symbol for current instruction
    ea - Effective address for current instruction
    src - Source info for current instruction
Do not allow the following information to be displayed at the prompt:
    dis - Disassembly of current instruction
    reg - Register state
```

[Send comments about this topic to Microsoft](#)

.push (Save Debugger State)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.push** command saves the current state of the debugger.

```
.push
.push /r
.push /r /q
```

Parameters

/r

Specifies that the current values in the pseudo-registers **\$t0** to **\$t19** should be saved. If the **/r** parameter is not used, these values are not saved by the **.push** command.

/q

Specifies that the command executes quietly. That is, the command executes without displaying any output.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

This command is most useful when used with [scripts](#) and [debugger command programs](#) so that they can work with one fixed state. To restore the debugger to a state that was previously saved using this command, use the [.pop \(Restore Debugger State\)](#) command. If the command is successful, no output is displayed.

[Send comments about this topic to Microsoft](#)

.quit_lock (Prevent Accidental Quit)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.quit_lock** command sets a password to prevent you from accidentally ending the debugging session.

```
.quit_lock /s NewPassword
.quit_lock /q Password
.quit_lock
```

Parameters

/s **** *NewPassword*

Prevents the debugging session from ending and stores *NewPassword*. You cannot end the debugger session until you use the **.quit_lock /q** command together with this same password. *NewPassword* can be any string. If it contains spaces, you must enclose *NewPassword* in quotation marks.

/q **** *Password*

Enables the debugging session to end. *Password* must match the password that you set with the **.quit_lock /s** command.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

Without parameters, **.quit_lock** displays the current lock status, including the full text of the password.

You can repeat the **.quit_lock /s** command to change an existing password.

When you use **.quit_lock /q**, the lock is removed. This command does not close the debugger. Instead, the command only enables you to exit the session in the typical manner when you want to.

Note The password is not "secret". Any remote user who is attached to the debugging session can use **.quit_lock** to determine the password. The purpose of this command is to prevent accidental use of the **q (Quit)** command. This command is especially useful if restarting the debugging session might be difficult (for example, during remote debugging).

You cannot use the **.quit_lock /s** command in **Secure Mode**. If you use this command before Secure Mode is activated, the password protection remains, but you cannot change or remove the password.

[Send comments about this topic to Microsoft](#)

.readmem (Read Memory from File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.readmem** command reads raw binary data from the specified file and copies the data to the target computer's memory.

```
.readmem FileName Range
```

Parameters

FileName

Specifies the name of the file to read. You can specify a full path or only the file name. If the file name contains spaces, enclose *FileName* in quotation marks. If you do not specify a path, the debugger uses the current directory.

Range

Specifies the address range for putting the data in memory. This parameter can contain a starting and ending address or a starting address and an object count. For more information about the syntax, see [Address and Address Range Syntax](#).

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Remarks

The memory data is copied literally to the target computer. The debugger does not parse the data in any way. For example, the **.readmem myfile 1000 10** command copies 10 bytes from the Myfile file and stores them in the target computer's memory, starting at address 1000.

The **.readmem** command is the opposite of the [.writemem \(Write Memory to File\)](#) command.

[Send comments about this topic to Microsoft](#)

.reboot (Reboot Target Computer)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.reboot** command restarts the target computer.

```
.reboot
```

Environment

Modes	Kernel mode only
Targets	Live debugging only
Platforms	All

Additional Information

For more information about related commands and an explanation of how the restart process affects the debugger, see [Crashing and Rebooting the Target Computer](#).

[Send comments about this topic to Microsoft](#)

.record_branches (Enable Branch Recording)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.record_branches** command enables the recording of branches that the target's code executed.

```
.record_branches {1|0}  
.record_branches
```

Environment

Modes	User mode, kernel mode
Targets	Live debugging only
Platforms	x64-based only

Remarks

The **.record_branches 1** command enables the recording of branches in the target's code. The **.record_branches 0** command disables this recording.

Without parameters, **.record_branches** displays the current status of this setting.

[Send comments about this topic to Microsoft](#)

.reload (Reload Module)

5/31/2017 • 4 min to read • [Edit Online](#)

The **.reload** command deletes all symbol information for the specified module and reloads these symbols as needed. In some cases, this command also reloads or unloads the module itself.

```
.reload [Options] [Module[=Address[,Size[,Timestamp]]]]  
.reload -?
```

Parameters

Options

Any of the following options:

/d

Reloads all modules in the debugger's module list. (When you omit all parameters, this situation is the default during user-mode debugging.)

/f

Forces the debugger to immediately load the symbols. This parameter overrides *lazy symbol loading*. For more information, see the following Remarks section.

/i

Ignores a mismatch in the .pdb file versions. (If you do not include this parameter, the debugger does not load mismatched symbol files.) When you use **/i**, **/f** is used also, even if you do not explicitly specify it.

/l

Lists the modules but does not reload their symbols. (In kernel mode, this parameter gives the same output as the **!drivers** extension.)

/n

Reloads kernel symbols only. This parameter does not reload any user symbols. (You can use this option only during kernel-mode debugging.)

/o

Forces the cached files in a symbol server's downstream store to be overwritten. When you use this flag, you should also include **/f**. By default, the downstream store files are never overwritten.

Because the symbol server uses distinct file names for the symbols of every different build of a binary, you do not have to use this option unless you believe your downstream store has become corrupted.

/s

Reloads all modules in the system's module image list. (When you omit all parameters, this situation is the default during kernel-mode debugging.)

If you are loading an individual system module by name while you perform user-mode debugging, you must include **/s**.

/u

Unloads the specified module and all its symbols. The debugger unloads any loaded module whose name matches *Module*, regardless of the full path. Image names are also searched. For more information, see the note in the following Remarks section.

/unl

Reloads symbols based on the image information in the unloaded module list.

/user

Reloads user symbols only. (You can use this option only during kernel-mode debugging.)

/v

Turns on verbose mode.

/w

Treats *Module* as a literal string. This treatment prevents the debugger from expanding wildcard characters.

Module

Specifies the name of an image on the target system for which to reload symbols on the host computer. *Module* should include the name and file name extension of the file. Unless you use the **/w** option, *Module* might contain a variety of wildcard characters and specifiers. For more information about the syntax, see [String Wildcard Syntax](#). If you omit *Module*, the behavior of the **.reload** command depends on which *Options* you use.

Address

Specifies the base address of the module. Typically, you have to have this address only if the image header has been corrupted or is paged out.

Size

Specifies the size of the module image. In many situations, the debugger knows the correct size of the module. When the debugger does not know the correct size, you should specify *Size*. This size can be the actual module size or a larger number, but the size should not be a smaller number. Typically, you have to have this size only if the image header has been corrupted or is paged out.

Timestamp

Specifies the timestamp of the module image. In many situations, the debugger knows the correct timestamp of the module. When the debugger does not know the timestamps, you should specify *Timestamp*. Typically, you have to have this timestamp only if the image header has been corrupted or is paged out.

Note There must be no blank space between the *Address*, *Size*, and *Timestamp* parameters.

-?

Displays a short help text for this command.

Environment

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about deferred (lazy) symbol loading, see [Deferred Symbol Loading](#). For more information about other symbol options, see [Setting Symbol Options](#).

Remarks

The **.reload** command does not cause symbol information to be read. Instead, this command lets the debugger know that the symbol files might have changed or that a new module should be added to the

module list. This command causes the debugger to revise its module list and delete its symbol information for the specified modules. The actual symbol information is not read from the individual .pdb files until the information is needed. (This kind of loading is known as *lazy symbol loading* or *deferred symbol loading*.)

You can force symbol loading to occur by using the **/f** option or by issuing an [!ld \(Load Symbols\)](#) command.

The **.reload** command is useful if the system stops responding (that is, crashes), which might cause you to lose symbols for the target computer that is being debugged. The command can also be useful if you have updated the symbol tree.

If the image header is incorrect for some reason, such as the module being unloaded, or is paged out, you can load symbols correctly by using the **/unl** argument, or specifying both *Address* and *Size*.

The **.reload /u** command performs a broad search. The debugger first tries to match *Module* with an exact module name, regardless of path. If the debugger cannot find this match, *Module* is treated as the name of the loaded image. For example, if the HAL that resides in memory has the module name of halacpi.dll, both of the following commands unload its symbols.

```
kd> .reload /u halacpi.dll
kd> .reload /u hal
```

If you are performing user-mode debugging and want to load a module that is not part of the target application's module list, you must include the **/s** option, as the following example shows.

```
0:000> .reload /u ntdll.dll
Unloaded ntdll.dll

0:000> .reload /s /f ntdll.dll
```

[Send comments about this topic to Microsoft](#)

.remote (Create Remote.exe Server)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.remote** command starts a [Remote.exe Server](#), enabling a remote connection to the current debugging session.

```
.remote session
```

Parameters

session

Specifies a name that you give to the debugging session.

Environment

You can use the **.remote** command in KD and CDB, but you cannot use it in WinDbg.

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about how to use Remote.exe Servers and Remote.exe Clients, see [Remote Debugging Through Remote.exe](#).

Remarks

The **.remote** command creates a Remote.exe process and turns the current debugger into a Remote.exe Server. This server enables a Remote.exe Client to connect to the current debugging session.

[Send comments about this topic to Microsoft](#)

.remote_exit (Exit Debugging Client)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.remote_exit** command exits the debugging client but does not end the debugging session.

```
.remote_exit [FinalCommands]
```

Parameters

FinalCommands

Specifies a command string to pass to the debugging server. You should separate multiple commands by using semicolons. These commands are passed to the debugging server and the connection is then broken.

Environment

You can use the **.remote_exit** command only in a script file. You can use it in KD and CDB, but you cannot use it in WinDbg.

Modes	User mode, kernel mode
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about script files, see [Using Script Files](#). For more information about debugging clients and debugging servers, see [Remote Debugging Through the Debugger](#).

Remarks

If you are using KD or CDB directly, instead of using a script, you can exit from the debugging client by using the **CTRL+B** key.

You cannot exit from a debugging client through a script that is executed in WinDbg.

[Send comments about this topic to Microsoft](#)

.restart (Restart Target Application)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.restart** command restarts the target application.

Do not confuse this command with the [.restart \(Restart Kernel Connection\)](#) command, which works only in kernel mode.

```
.restart
```

Environment

Modes	User mode only
Targets	Live debugging only
Platforms	All

Additional Information

For more information about how to issue this command and an overview of related commands, see [Controlling the Target](#).

Remarks

CDB and WinDbg can restart a target application if the debugger originally created the application. You can use the **.restart** command even if the target application has already closed.

However, if the application is running and the debugger is later attached to the process, the **.restart** command has no effect.

After the process is restarted, it immediately breaks into the debugger.

In WinDbg, use the [View | WinDbg Command Line](#) command if you started your target from the WinDbg command prompt and you want to review this command line before you decide whether to use **.restart**.

[Send comments about this topic to Microsoft](#)

.restart (Restart Kernel Connection)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.restart** command restarts the kernel connection.

Do not confuse this command with the [.restart \(Restart Target Application\)](#) command, which works only in user mode.

```
.restart
```

Environment

You can use the **.restart** command only in KD.

Modes	Kernel mode only
Targets	Live, crash dump
Platforms	All

Additional Information

For more information about reestablishing contact with the target, see [Synchronizing with the Target Computer](#).

Remarks

The **.restart** command is similar to the [CTRL+R \(Re-synchronize\)](#) command, except that **.restart** is even more extensive in its effect. This command is equivalent to ending the debugger and then attaching a new debugger to the target computer.

The **.restart** command is most useful when you are performing [remote debugging through remote.exe](#) and ending and restarting the debugger might be difficult. However, you cannot use **.restart** from a debugging client if you are performing remote debugging through the debugger.

[Send comments about this topic to Microsoft](#)

.rrestart (Register for Restart)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.rrestart** command registers the debugging session for restart in case of a reboot or an application failure.

```
.rrestart
```

Remarks

This command does not work for elevated debugger sessions.

See also

[.urestart](#)

[Send comments about this topic to Microsoft](#)

.scroll_prefs (Control Source Scrolling Preferences)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.scroll_prefs** command controls the positioning of the source in a Source window when scrolling to a line.

```
.scroll_prefs Before After
.scroll_prefs
```

Parameters

Before

Specifies how many source lines before the line you are scrolling to should be visible in the Source window.

After

Specifies how many source lines after the line you are scrolling to should be visible in the Source window.

Environment

This command is available only in WinDbg and cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

When this command is used with no parameters, the current source scrolling preferences are displayed.

[Send comments about this topic to Microsoft](#)

.scriptlist (List Loaded Scripts)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.scriptlist** command lists the loaded scripts.

```
.scriptlist
```

Parameters

None

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

The .scriptlist command will list any scripts which have been loaded via the .scriptload command.

If the TestScript was successfully loaded using .scriptload, the .scriptlist command would display the name of the loaded script.

```
0:000> .scriptlist
Command Loaded Scripts:
  JavaScript script from 'C:\WinDbg\Scripts\TestScript.js'
```

Requirements

Before using any of the .script commands, a scripting provider needs to be loaded. Use the [.load \(Load Extension DLL\)](#) command to load the JavaScript provider.

```
0:000> .load jsprovider.dll
```

See also

[JavaScript Debugger Scripting](#)

[.scriptload \(Load Script\)](#)

[Send comments about this topic to Microsoft](#)

.scriptload (Load Script)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.scriptload** command will load and execute the specified script file.

```
.scriptload ScriptFile
```

Parameters

ScriptFile

Specifies the name of the script file to load. *ScriptFile* should include the .js file name extension. Absolute or relative paths can be used. Relative paths are relative to the directory that you started the debugger in. File paths containing spaces are not supported.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

The .scriptload command will load a script and execute a script. The following command shows the successful load of TestScript.js.

```
0:000> .scriptload C:\WinDbg\Scripts\TestScript.js
JavaScript script successfully loaded from 'C:\WinDbg\Scripts\TestScript.js'
```

If there are any errors in the initial load and execution of the script, the errors will be displayed to console, including the line number and error message.

```
0:000:x86> .scriptload C:\WinDbg\Scripts\TestScript.js
0:000> "C:\WinDbg\Scripts\TestScript.js" (line 11 (@ 1)): Error (0x80004005): Syntax error
Error: Unable to execute JavaScript script 'C:\WinDbg\Scripts\TestScript.js'
```

The .scriptload command will execute the following in a JavaScript.

- root code
- initializeScript function (if present in the script)

When a script is loaded using the .scriptload command, the initializeScript function and the root code of the script is executed, the names which are present in the script are bridged into the root namespace of the debugger (dx Debugger) and the script stays resident in memory until it is unloaded and all references to its objects are released.

The script can provide new functions to the debugger's expression evaluator, modify the object model of the

debugger, or can act as a visualizers in much the same way that a NatVis visualizer does. For more information about NavVis and the debugger, see [dx \(Display NatVis Expression\)](#).

For more information about working with JavaScript, see [JavaScript Debugger Scripting](#). For more information about the debugger objects, see [Native Objects in JavaScript Extensions](#).

Requirements

Before using any of the .script commands, a scripting provider needs to be loaded. Use the [.load \(Load Extension DLL\)](#) command to load the JavaScript provider.

```
0:000> .load jsprovider.dll
```

See also

[.scriptunload \(Unload Script\)](#)

[JavaScript Debugger Scripting](#)

[Send comments about this topic to Microsoft](#)

.scriptproviders (List Script Providers)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.scriptproviders** command lists the active script providers.

```
.scriptproviders
```

Parameters

None

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

The .scriptproviders command will list all the script languages which are presently understood by the debugger and the extension under which they are registered. Any file ending in ".NatVis" is understood as a NatVis script and any file ending in ".js" is understood as a JavaScript script. Either type of script can be loaded with the .scriptload command.

In the example below, the JavaScript and NatVis providers are loaded.

```
0:000> .scriptproviders
Available Script Providers:
  NatVis (extension '.NatVis')
  JavaScript (extension '.js')
```

Requirements

Before using any of the .script commands, a scripting provider needs to be loaded. Use the [.load \(Load Extension DLL\)](#) command to load the JavaScript provider.

```
0:000> .load jsprovider.dll
```

See also

[JavaScript Debugger Scripting](#)

[.scriptload \(Load Script\)](#)

[Send comments about this topic to Microsoft](#)

.scriptrun (Run Script)

5/31/2017 • 1 min to read • [Edit Online](#)

The .scriptrun command will load and run a JavaScript.

```
.scriptrun ScriptFile
```

Parameters

ScriptFile

Specifies the name of the script file to load and execute. *ScriptFile* should include the .js file name extension.

Absolute or relative paths can be used. Relative paths are relative to the directory that you started the debugger in.

File paths containing spaces are not supported.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

The .scriptrun command will load a script and, execute the following code.

- root
- initializeScript
- invokeScript

A confirmation message is displayed when the code is loaded and executed.

```
0:000> .scriptrun C:\WinDbg\Scripts\helloWorld.js
JavaScript script successfully loaded from 'C:\WinDbg\Scripts\helloWorld.js'
Hello World!  We are in JavaScript!
```

Any object model manipulations made by the script will stay in place until the script is subsequently unloaded or is run again with different content.

This table summarizes which functions are executed by .scriptload and .scriptrun.

	.scriptload	.scriptrun
root	yes	yes
initializeScript	yes	yes
invokeScript		yes

uninitializeScript

You can use this code to see which functions are called with the .script run command.

```
// Root of Script
host.diagnostics.debugLog("****>; Code at the very top (root) of the script is always run \n");

function initializeScript()
{
    // Add code here that you want to run everytime the script is loaded.
    // We will just send a message to indicate that function was called.
    host.diagnostics.debugLog("****>; initializeScript was called \n");
}

function invokeScript()
{
    // Add code here that you want to run everytime the script is executed.
    // We will just send a message to indicate that function was called.
    host.diagnostics.debugLog("****>; invokeScript was called \n");
}
```

For more information about working with JavaScript, see [JavaScript Debugger Scripting](#). For more information about the debugger objects, see [Native Objects in JavaScript Extensions](#).

Requirements

Before using any of the .script commands, a scripting provider needs to be loaded. Use the [.load \(Load Extension DLL\)](#) command to load the JavaScript provider dll.

```
0:000> .load C:\ScriptProviders\jsprovider.dll
```

See also

[.scriptload \(Load Script\)](#)

[JavaScript Debugger Scripting](#)

[Send comments about this topic to Microsoft](#)

.scriptunload (Unload Script)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.scriptunload** command unloads the specified script.

```
.scriptunload ScriptFile
```

Parameters

ScriptFile

Specifies the name of the script file to unload. *ScriptFile* should include the .js file name extension. Absolute or relative paths can be used. Relative paths are relative to the directory that you started the debugger in. File paths containing spaces are not supported.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

The .scriptunload command unloads a loaded script. Use the following command syntax to unload a script

```
0:000:x86> .scriptunload C:\WinDbg\Scripts\TestScript.js
JavaScript script unloaded from 'C:\WinDbg\Scripts\TestScript.js'
```

If there are outstanding references to objects in a script, the contents of the script will be unlinked but the script may remain in memory until all such references are released.

For more information about working with JavaScript, see [JavaScript Debugger Scripting](#). For more information about the debugger objects, see [Native Objects in JavaScript Extensions](#).

Requirements

Before using any of the .script commands, a scripting provider needs to be loaded. Use the [.load \(Load Extension DLL\)](#) command to load the JavaScript provider dll.

```
0:000> .load C:\ScriptProviders\jsprovider.dll
```

See also

[.scriptload \(Load Script\)](#)

[JavaScript Debugger Scripting](#)

[Send comments about this topic to Microsoft](#)

.secure (Activate Secure Mode)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.secure** command activates or displays the status of Secure Mode.

```
.secure 1  
.secure
```

Environment

Secure Mode can only be enabled while the debugger is dormant. Secure Mode applies only to kernel-mode sessions because, by definition, Secure Mode prevents user-mode debugging operations.

Modes	kernel mode only
Targets	live, crash dump
Platforms	all

Additional Information

For details, see [Secure Mode](#).

Remarks

To activate Secure Mode, use the command **.secure 1** (or **.secure** followed by any nonzero value).

The command **.secure** will show whether Secure Mode is currently active.

[Send comments about this topic to Microsoft](#)

.send_file (Send File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.send_file** command copies files. If you are performing remote debugging through a process server, it sends a file from the smart client's computer to the process server's computer.

```
.send_file [-f] Source Destination
.send_file [-f] -s Destination
```

Parameters

-f

Forces file creation. By default, **.send_file** will not overwrite any existing files. If the **-f** switch is used, the destination file will always be created, and any existing file with the same name will be overwritten.

Source

Specifies the full path and filename of the file to be sent. If you are debugging through a process server, this file must be located on the computer where the smart client is running.

Destination

Specifies the directory where the file is to be written. If you are debugging through a process server, this directory name is evaluated on the computer where the process server is running.

-s

Causes the debugger to copy all loaded symbol files.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

This command is particularly useful when you have been performing remote debugging through a process server, but wish to begin debugging locally instead. In this case you can use the **.send_file -s** command to copy all the symbol files that the debugger has been using to the process server. These symbol files can then be used by a debugger running on the local computer.

[Send comments about this topic to Microsoft](#)

.server (Create Debugging Server)

5/31/2017 • 4 min to read • [Edit Online](#)

The **.server** command starts a debugging server, allowing a remote connection to the current debugging session.

```
.server npipe:pipe=PipeName[,hidden][,password=Password][,IcfEnable]
.server tcp:port=Socket[,hidden][,password=Password][,ipversion=6][,IcfEnable]
.server tcp:port=Socket,clicon=Client[,password=Password][,ipversion=6]
.server com:port=COMPort,baud=BaudRate,channel=COMChannel[,hidden][,password=Password]
.server spipe:proto=Protocol,{certuser=Cert|machuser=Cert},pipe=PipeName[,hidden][,password=Password]
.server ssl:proto=Protocol,{certuser=Cert|machuser=Cert},port=Socket[,hidden][,password=Password]
.server ssl:proto=Protocol,{certuser=Cert|machuser=Cert},port=Socket,clicon=Client[,password=Password]
```

Parameters

PipeName

When NPIPE or SPIPE protocol is used, *PipeName* is a string that will serve as the name of the pipe. Each pipe name should identify a unique debugging server. If you attempt to reuse a pipe name, you will receive an error message. *PipeName* must not contain spaces or quotation marks. *PipeName* can include a numerical **printf**-style format code, such as %x or %d. The debugger will replace this with the process ID of the debugger. A second such code will be replaced with the thread ID of the debugger.

Socket

When TCP or SSL protocol is used, *Socket* is the socket port number.

It is also possible to specify a range of ports separated by a colon. The debugger will check each port in this range to see if it is free. If it finds a free port and no error occurs, the debugging server will be created. The debugging client will have to specify the actual port being used to connect to the server. To determine the actual port, use any of the methods described in [Searching for Debugging Servers](#); when this debugging server is displayed, the port will be followed by two numbers separated by a colon. The first number will be the actual port used; the second can be ignored. For example, if the port was specified as port=51:60, and port 53 was actually used, the search results will show "port=53:60". (If you are using the **clicon** parameter to establish a reverse connection, the debugging client can specify a range of ports in this manner, while the server must specify the actual port used.)

clicon=Client

When TCP or SSL protocol is used and the **clicon** parameter is specified, a *reverse connection* will be opened. This means that the debugging server will try to connect to the debugging client, instead of letting the client initiate the contact. This can be useful if you have a firewall that is preventing a connection in the usual direction. *Client* specifies the network name of the machine on which the debugging client exists or will be created. The two initial backslashes (\) are optional.

When **clicon** is used, it is best to start the debugging client before the debugging server is created, although the usual order (server before client) is also permitted. A reverse-connection server will not appear when another debugger displays all active servers.

COMPort

When COM protocol is used, *COMPort* specifies the COM port to be used. The prefix COM is optional (for example, both "com2" and "2" are acceptable).

BaudRate

When COM protocol is used, *BaudRate* specifies the baud rate at which the connection will run. Any baud rate that is supported by the hardware is permitted.

COMChannel

If COM protocol is used, *COMChannel* specifies the COM channel to be used in communicating with the debugging client. This can be any value between 0 and 254, inclusive.

Protocol

If SSL or SPIPE protocol is used, *Protocol* specifies the Secure Channel (S-Channel) protocol. This can be any one of the strings tls1, pct1, ssl2, or ssl3.

Cert

If SSL or SPIPE protocol is used, *Cert* specifies the certificate. This can either be the certificate name or the certificate's thumbprint (the string of hexadecimal digits given by the certificate's snapin). If the syntax **certuser=Cert** is used, the debugger will look up the certificate in the system store (the default store). If the syntax **machuser=Cert** is used, the debugger will look up the certificate in the machine store. The specified certificate must support server authentication.

hidden

Prevents the server from appearing when another debugger displays all active servers.

password=Password

Requires a debugging client to supply the specified password in order to connect to the debugging session. *Password* can be any alphanumeric string, up to twelve characters in length.

ipversion=6

(Debugging Tools for Windows 6.6.07 and earlier only) Forces the debugger to use IP version 6 rather than version 4 when using TCP to connect to the Internet. In Windows Vista and later versions, the debugger attempts to auto-default to IP version 6, making this option unnecessary.

IcfEnable

(Windows XP and later versions only) Causes the debugger to enable the necessary port connections for TCP or named pipe communication when the Internet Connection Firewall is active. By default, the Internet Connection Firewall disables the ports used by these protocols. When **IcfEnable** is used with a TCP connection, the debugger causes Windows to open the port specified by the *Socket* parameter. When **IcfEnable** is used with a named pipe connection, the debugger causes Windows to open the ports used for named pipes (ports 139 and 445). The debugger does not close these ports after the connection terminates.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For full details on how to start a debugging server, see [Activating a Debugging Server](#). For examples, see [Client and Server Examples](#).

Remarks

This command turns the current debugger into a debugging server. This allows you to start the server after the debugger is already running, whereas the [-server command-line option](#) can only be issued when the debugger is started.

This permits a debugging client to connect to the current debugging session. Note that it is possible to start

multiple servers using different options, allowing different kinds of debugging clients to join the session.

[Send comments about this topic to Microsoft](#)

.servers (List Debugging Servers)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.servers** command lists all debugging servers that have been established by this debugger.

```
.servers
```

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For full details on debugging servers, see [Remote Debugging Through the Debugger](#).

Remarks

The output of the **.servers** command lists all the debugging servers started by the debugger on which this command is issued. The output is formatted so that it can be used literally as the argument for the **-remote** command-line option or pasted into the WinDbg dialog box.

Each debugging server is identified by a unique ID. This ID can be used as the argument for the [.endsrv \(End Debugging Server\)](#) command, if you wish to terminate the debugging server.

The **.servers** command does not list debugging servers started on this computer by different instances of the debugger, nor does it list process servers or KD connection servers.

[Send comments about this topic to Microsoft](#)

.setdll (Set Default Extension DLL)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.setdll** command changes the default extension DLL for the debugger.

```
.setdll DLLName
!DLLName.setdll
```

Parameters

DLLName

The name and path of the extension DLL. If the full path was specified when the DLL was loaded, it needs to be given in full here as well.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For details on loading, unloading, and controlling extensions, see [Loading Debugger Extension DLLs](#). For details on executing extension commands, see [Using Debugger Extension Commands](#).

Remarks

The debugger maintains a default extension DLL that is implicitly loaded when the debugger is started. This allows the user to specify an extension command without first having to load an extension DLL. This command allows modification of which DLL is loaded as the default DLL.

When a command is issued, the debugger looks for it in the default extension first. If a match is not found, all other loaded extension DLLs are searched in the order they were loaded.

[Send comments about this topic to Microsoft](#)

.shell (Command Shell)

5/31/2017 • 3 min to read • [Edit Online](#)

The **.shell** command launches a shell process and redirects its output to the debugger, or to a specified file.

```
.shell [Options] [ShellCommand]
.shell -i InFile [-o OutFile [-e ErrFile]] [Options] ShellCommand
```

Parameters

InFile

Specifies the path and file name of a file to be used for input. If you intend to offer no input after the initial command, you can specify a single hyphen (-) instead of *InFile*, with no space before the hyphen.

OutFile

Specifies the path and file name of a file to be used for standard output. If **-o** *OutFile* is omitted, output is sent to the Debugger Command window. If you do not want this output displayed or saved in a file, you can specify a single hyphen (-) instead of *OutFile*, with no space before the hyphen.

ErrFile

Specifies the path and file name of a file to be used for error output. If **-e** *ErrFile* is omitted, error output is sent to the same place as standard output. If you do not want this output displayed or saved in a file, you can specify a single hyphen (-) instead of *ErrFile*, with no space before the hyphen.

Options

Can be any number of the following options:

-ci "Commands"

Processes the specified debugger commands, and then passes their output as an input file to the process being launched. *Commands* can be any number of debugger commands, separated by semicolons, and enclosed in quotation marks.

-x

Causes any process being spawned to be completely detached from the debugger. This allows you to create processes which will continue running even after the debugging session ends.

ShellCommand

Specifies the application command line or Microsoft MS-DOS command to be executed.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For other ways of accessing the command shell, see [Using Shell Commands](#).

Remarks

The **.shell** command is not supported when the output of a user-mode debugger is redirected to the kernel debugger. For more information about redirecting output to the kernel debugger (sometimes called NTSD over KD), see [Controlling the User-Mode Debugger from the Kernel Debugger](#).

The entire line after the **.shell** command will be interpreted as a Windows command (even if it contains a semicolon). This line should not be enclosed in quotation marks. There must be a space between **.shell** and the *ShellCommand* (additional leading spaces are ignored).

The output from the command will appear in the Debugger Command window, unless the **-o **** OutFile** parameter is used.

Issuing a **.shell** command with no parameters will activate the shell and leave it open. All subsequent commands will be interpreted as Windows commands. During this time, the debugger will display messages reading **<.shell process may need input>**, and the WinDbg prompt will be replaced with an **Input>** prompt. Sometimes, a separate Command Prompt window will appear when the debugger leaves the shell open. This window should be ignored; all input and output will be done through the Debugger Command window.

To close this shell and return to the debugger itself, type **exit** or **.shell_quit**. (The **.shell_quit** command is more powerful, because it works even if the shell is frozen.)

This command cannot be used while debugging CSRSS, because new processes cannot be created without CSRSS being active.

You can use the **-ci** flag to run one or more debugger commands and then pass their output to a shell process. For example, you could pass the output from the **!process 0 7** command to a Perl script by using the following command:

```
0:000> .shell -ci "!process 0 7" perl.exe parsemyoutput.pl
```

[Send comments about this topic to Microsoft](#)

.settings (Set Debug Settings)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.settings** command sets, modifies, displays, loads and saves settings in the Debugger.Settings namespace.

```
.settings set namespace.setting=value
.settings set namespace.setting+=value
.settings save [file path]
.settings load file path
.settings list [namespace][-v]
.settings help
```

Parameters

.settings set parameters

namespace.setting=value

Sets or modifies a setting. When specifying file paths use slash escaping, for example C:\\Symbols\\.

Examples:

```
.settings set Display.PreferDMLOutput=false
.settings set Sources.DisplaySourceLines=true
.settings set Symbols.Sympath="C:\\Symbols\\"
```

namespace.setting+=value

Specifies that the new value will be appended to (rather than replace) the previous value.

Example:

```
.settings set Extensions.ExtensionSearchPath+=";C:\\MyExtension\\"
```

.setting save parameters

file path

Saves all of the values in the Debugger.Settings namespace to the specified XML file.

none

If a file path is not provided, the settings will be saved to the last file that was loaded or saved to. If a previous file does not exist, a file named config.xml will be created in the directory that the debugger executable was loaded from.

.setting load parameters

file path

Loads all the settings from an XML settings file. Loading settings will change only the settings that are defined in that file. Any previously loaded or changed settings that do not appear in that file will not be modified. This file will be treated as your default save path until the next save or load operation.

.setting list parameters

namespace

List all settings in the given namespace and their values.

-v

The `-v` flag causes a description of the setting to be displayed.

.setting help parameters

None

Lists all of the settings in the Debugger namespace and their description.

Namespace

Lists all settings in the given namespace and their description.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

On launch, the debugger will load all the settings from config.xml in the directory the debugger executable is in. Throughout your debugging session you can modify settings using the previous settings command (like `.sympath` or `.prefer_dml`) or the new `.settings` commands. You can use `'.settings save'` to save your settings to your settings configuration file. You can use the following command to enable AutoSave.

```
.settings set AutoSaveSettings=true
```

When auto save is enabled, the settings in the `Debugger.Settings` namespace will be automatically saved when exiting the debugger.

Remarks

You can exchange debug xml settings files with others to duplicate their debug settings.

[Send comments about this topic to Microsoft](#)

.show_read_failures

5/31/2017 • 1 min to read • [Edit Online](#)

The **.show_read_failures** command enables or disables the display of read failures.

```
.show_read_failures /v
.show_sym_failures /V
```

Parameters

/v

Enables the display of read failures.

/V

Disables the display of read failures.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

[Send comments about this topic to Microsoft](#)

.show_sym_failures

5/31/2017 • 1 min to read • [Edit Online](#)

The **.show_sym_failures** command enables or disables the display of symbol lookup failures and type lookup failures.

```
.show_sym_failures /s
.show_sym_failures /S
.show_sym_failures /t
.show_sym_failures /T
```

Parameters

/s

Enables the display of symbol lookup failures.

/S

Disables the display of symbol lookup failures.

/t

Enables the display of type lookup failures.

/T

Disables the display of type lookup failures.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

[Send comments about this topic to Microsoft](#)

.sleep (Pause Debugger)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.sleep** command causes the user-mode debugger to pause and the target computer to become active. This command is only used when you are controlling the user-mode debugger from the kernel debugger.

```
.sleep milliseconds
```

Parameters

milliseconds

Specifies the length of the pause, in milliseconds.

Environment

Modes	controlling the user-mode debugger from the kernel debugger
Targets	live debugging only
Platforms	all

Additional Information

For details and information about how to wake up a debugger in sleep mode, see [Controlling the User-Mode Debugger from the Kernel Debugger](#).

Remarks

When you are controlling the user-mode debugger from the kernel debugger, and the user-mode debugger prompt is visible in the kernel debugger, this command will activate sleep mode. The kernel debugger, the user-mode debugger, and the target application will all freeze, but the rest of the target computer will become active.

If you use this command in any other scenario, it will simply freeze the debugger for a period of time.

The sleep time is in milliseconds and interpreted according to the default radix, unless a prefix such as **0n** is used. Thus, if the default radix is 16, the following command will cause about 65 seconds of sleep:

```
0:000> .sleep 10000
```

[Send comments about this topic to Microsoft](#)

.sound_notify (Use Notification Sound)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.sound_notify** command causes a sound to be played when WinDbg enters the wait-for-command state.

```
.sound_notify /ed
.sound_notify /ef File
.sound_notify /d
```

Parameters

/ed

Causes the default Windows alert sound to be played when WinDbg enters the wait-for-command state.

/ef ** File**

Causes the sound contained in the specified file to be played when WinDbg enters the wait-for-command state.

/d

Disables the playing of sounds.

Environment

This command is available only in WinDbg and cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Targets	all

[Send comments about this topic to Microsoft](#)

.srcfix, .lsrcfix (Use Source Server)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.srcfix** and **.lsrcfix** commands automatically set the source path to indicate that a source server will be used.

```
.srcfix[+] [Paths]  
.lsrcfix[+] [Paths]
```

Parameters

+

Causes the existing source path to be preserved, and ;**srv*** to be appended to the end. If the **+** is not used, the existing source path is replaced.

Paths

Specifies one or more additional paths to append to the end of the new source path.

Environment

The **.srcfix** command is available on all debuggers. The **.lsrcfix** command is available only in WinDbg and cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For more information on setting the local source path for a remote client, see [WinDbg Command-Line](#)

Options. For details about [SrcSrv](#), see [Using a Source Server](#). For details on the source path and the local source path, see [Source Path](#). For more information about commands that can be used while performing remote debugging through the debugger, see [Controlling a Remote Debugging Session](#).

Remarks

When you add **srv*** to the source path, the debugger uses [SrcSrv](#) to retrieve source files from locations specified in the target modules' symbol files. Using **srv*** in the source path is fundamentally different from using **srv*** in the symbol path. In the symbol path, you can specify a symbol server location along with the **srv*** (for example, **.sympath SRV*https://msdl.microsoft.com/download/symbols**). In the source path, **srv*** stands alone, separated from all other elements by semicolons.

When this command is issued from a debugging client, **.srcfix** sets the source path to use a source server on the debugging server, while **.lsrcfix** does the same on the local machine.

These commands are the same as the [.srcpath \(Set Source Path\)](#) and [.lsrcpath \(Set Local Source Path\)](#) commands followed by the **srv*** source path element. Thus, the following two commands are equivalent:

```
.srcfix[+] [Paths]  
.srcpath[+] srv*[;Paths]
```

Similarly, the following two commands are equivalent:

```
.lsrcfix[+] [Paths]  
.lsrcpath[+] srv*[;Paths]
```

[Send comments about this topic to Microsoft](#)

.srcnoisy (Noisy Source Loading)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.srcnoisy** command controls the verbosity level for source file loading.

```
.srcnoisy [Options]
```

Parameters

Options

Can be any one of the following options:

0

Disables the display of extra messages.

1

Displays information about the progress of source file loading and unloading.

2

Displays information about the progress of symbol file loading and unloading.

3

Displays all information displayed by options 1 and 2.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

With no parameters, **.srcnoisy** will display the current status of noisy source loading.

Noisy source loading should not be confused with noisy symbol loading -- that is controlled by the **!sym noisy** extension and by other means of controlling the **SYMOPT_DEBUG** setting.

[Send comments about this topic to Microsoft](#)

.srcpath, .lsrcpath (Set Source Path)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.srcpath** and **.lsrcpath** commands set or display the source file search path.

```
.srcpath[+] [Directory [; ...]]  
.lsrcpath[+] [Directory [; ...]]
```

Parameters

+

Specifies that the new directories will be appended to (rather than replacing) the previous source file search path.

Directory

Specifies one or more directories to put in the search path. If *Directory* is not specified, the current path is displayed. Separate multiple directories with semicolons.

Environment

The **.srcpath** command is available on all debuggers. The **.lsrcpath** command is available only in WinDbg and cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For details and other ways to change this path, see [Source Path](#). For more information about commands that can be used while performing remote debugging through the debugger, see [Controlling a Remote Debugging Session](#).

Remarks

If you include `srv*` in your source path, the debugger uses `SrcSrv` to retrieve source files from locations specified in the target modules' symbol files. For more information about using `srv*` in a source path, see [Using a Source Server](#) and [.srcfix](#).

When this command is issued from a debugging client, **.srcpath** sets the source path on the debugging server, while **.lsrcpath** sets the source path on the local machine.

[Send comments about this topic to Microsoft](#)

.step_filter (Set Step Filter)

5/31/2017 • 2 min to read • [Edit Online](#)

The **.step_filter** command creates a list of functions that are skipped (stepped over) when tracing. This allows you to trace through code and skip only certain functions. It can also be used in source mode to control stepping when there are multiple function calls on one line.

```
.step_filter "FilterList"
.step_filter /c
.step_filter
```

Parameters

"FilterList"

Specifies the symbols associated with functions to be stepped over. *FilterList* can contain any number of text patterns separated by semicolons. Each of these patterns may contain a variety of wildcards and specifiers; see [String Wildcard Syntax](#) for details. A function whose symbol matches at least one of these patterns will be stepped over during tracing. Each time "*FilterList*" is used, any previous filter list is discarded and completely replaced with the new list.

/c

Clears the filter list.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

Without any parameters, **.step_filter** displays the current filter list.

Typically, a trace command (for example, **t** or the windbg **debug | step into** button ) traces into a function call. However, if the symbol associated with the function being called matches a pattern specified by *FilterList*, the function will be stepped over -- as if a step command (for example, **p**) had been used.

If the instruction pointer is located within code that is listed in the filter list, any trace or step commands will step out of this function, like the **gu** command or the WinDbg **Step Out** button. Of course, this filter would prevent such code from having been traced into in the first place, so this will only happen if you have changed the filter or hit a breakpoint.

For example, the following command will cause trace commands to skip over all CRT calls:

```
.step_filter "msvcrt!*" 
```

The **.step_filter** command is most useful when you are debugging in source mode, because there can be multiple function calls on a single source line. The **p** and **t** commands cannot be used to separate these function calls.

For example, in the following line, the **t** command will step into both GetTickCount and printf, while the **p** command will step over both function calls:

```
printf( "%x\n", GetTickCount() );
```

The **.step_filter** command allows you to filter out one of these calls while still tracing into the other.

Because the functions are identified by symbol, a single filter can include an entire module. This lets you filter out framework functions -- for example, Microsoft Foundation Classes (MFC) or Active Template Library (ATL) calls.

When debugging in assembly mode, each call is on a different line, so you can choose whether to step or trace line-by-line. So **.step_filter** is not very useful in assembly mode.

[Send comments about this topic to Microsoft](#)

.suspend_ui (Suspend WinDbg Interface)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.suspend_ui** command suspends the refresh of WinDbg debugging information windows.

```
.suspend_ui 0
.suspend_ui 1
.suspend_ui
```

Parameters

0

Suspends the refresh of WinDbg debugging information windows.

1

Enables the refresh of WinDbg debugging information windows.

Environment

This command is available only in WinDbg and cannot be used in script files.

Modes	kernel mode only
Targets	live, crash dump
Platforms	all

Additional Information

For information about debugging information windows, see [Using Debugging Information Windows](#).

Remarks

Without any parameters, **.suspend_ui** displays whether debugging information windows are currently suspended.

By default, debugging information windows are refreshed every time the information they display changes.

Suspending the refresh of these windows can speed up WinDbg during a sequence of quick operations -- for example, when tracing or stepping many times in quick succession.

[Send comments about this topic to Microsoft](#)

.symfix (Set Symbol Store Path)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.symfix** command automatically sets the symbol path to point to the Microsoft symbol store.

```
.symfix[+] [LocalSymbolCache]
```

Parameters

+

Causes the Microsoft symbol store path to be appended to the existing symbol path. If this is not included, the existing symbol path is replaced.

LocalSymbolCache

Specifies the directory to be used as a local symbol cache. If this directory does not exist, it will be created when the symbol server begins copying files. If *LocalSymbolCache* is omitted, the sym subdirectory of the debugger installation directory will be used.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For details, see [Using Symbol Servers and Symbol Stores](#).

Remarks

The following example shows how to use **.symfix** to set a new symbol path that points to the Microsoft symbol store.

```
3: kd> .symfix c:\myCache
3: kd> .sympath
Symbol search path is: srv*
Expanded Symbol search path is: cache*c:\myCache;SRV*https://msdl.microsoft.com/download/symbols
```

The following example shows how to use **.symfix+** to append the existing symbol path with a path that points to the Microsoft symbol store.

```
3: kd> .sympath
Symbol search path is: c:\someSymbols
Expanded Symbol search path is: c:\somesymbols
3: kd> .symfix+ c:\myCache
3: kd> .sympath
Symbol search path is: c:\someSymbols;srv*
Expanded Symbol search path is:
c:\somesymbols;cache*c:\myCache;SRV*https://msdl.microsoft.com/download/symbols
```

[Send comments about this topic to Microsoft](#)

.symopt (Set Symbol Options)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.symopt** command sets or displays the symbol options.

```
.symopt+ Flags
.symopt- Flags
.symopt
```

Parameters

+

Causes the symbol options specified by *Flags* to be set. If **.symopt** is used with *Flags* but no plus or minus sign, a plus sign is assumed.

-

Causes the symbol options specified by *Flags* to be cleared.

Flags

Specifies the symbol options to be changed. *Flags* must be the sum of the bit flags of these symbol options.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For a list and description of each symbol option, its bit flag, and other methods of setting and clearing these options, see [Setting Symbol Options](#).

Remarks

Without any arguments, **.symopt** displays the current symbol options.

[Send comments about this topic to Microsoft](#)

.sympath (Set Symbol Path)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.sympath** command sets or alters the symbol path. The symbol path specifies locations where the debugger looks for symbol files.

```
.sympath[+] [Path ; ...]
```

Parameters

+

Specifies that the new locations will be appended to (rather than replace) the previous symbol search path.

Path

A fully qualified path or a list of fully qualified paths. Multiple paths are separated by semicolons. If *Path* is omitted, the current symbol path is displayed.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For details and other ways to change this path, see [Symbol Path](#).

Remarks

New symbol information will not be loaded when the symbol path is changed. You can use the [.reload \(Reload Module\)](#) command to reload symbols.

[Send comments about this topic to Microsoft](#)

.thread (Set Register Context)

5/31/2017 • 4 min to read • [Edit Online](#)

The **.thread** command specifies which thread will be used for the register context.

```
.thread [/p [/r] ] [/P] [/w] [Thread]
```

Parameters

/p

(Live debugging only) If this option is included and *Thread* is nonzero, all transition page table entries (PTEs) for the process owning this thread will be automatically translated into physical addresses before access. This may cause slowdowns, because the debugger will have to look up the physical addresses for all the memory used by this process, and a significant amount of data may need to be transferred across the debug cable. (This behavior is the same as that of [.cache forcedecodeuser](#).)

If the **/p** option is included and *Thread* is zero or omitted, this translation will be disabled. (This behavior is the same as that of [.cache noforcedecodeuser](#).)

/r

(Live debugging only) If the **/r** option is included along with the **/p** option, user-mode symbols for the process owning this thread will be reloaded after the process and register contexts have been set. (This behavior is the same as that of [.reload /user](#).)

/P

(Live debugging only) If this option is included and *Thread* is nonzero, all transition page table entries (PTEs) will be automatically translated into physical addresses before access. Unlike the **/p** option, this translates the PTEs for all user-mode and kernel-mode processes, not only the process owning this thread. This may cause slowdowns, because the debugger will have to look up the physical addresses for all memory in use, and a huge amount of data may need to be transferred across the debug cable. (This behavior is the same as that of [.cache forcedecodepe](#)ts.)

/w

(64-bit kernel debugging only) Changes the active context for the thread to the WOW64 32-bit context. The thread specified must be running in a process that has a WOW64 state.

Thread

The address of the thread. If this is omitted or zero, the thread context is reset to the current thread.

Environment

Modes	kernel mode only
Targets	live, crash dump
Platforms	all

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

Remarks

Generally, when you are doing kernel debugging, the only visible registers are the ones associated with the current thread.

The **.thread** command instructs the kernel debugger to use the specified thread as the register context. After this command is executed, the debugger will have access to the most important registers and the stack trace for this thread. This register context persists until you allow the target to execute or use another register context command (**.thread**, **.cxr**, or **.trap**). See [Register Context](#) for full details.

The **/w** option can only be used in 64-bit kernel debugging sessions on a thread running in a process that has a WOW64 state. The context retrieved will be the last context remembered by WOW64; this is usually the last user-mode code executed by *Thread*. This option can only be used if the target is in native machine mode. For example, if the target is running on a 64-bit machine that is emulating an x86-based processor using WOW64, this option cannot be used. Using the **/w** option will cause the machine mode to switch automatically to an x86-based processor.

This command does not actually change the current thread. In other words, extensions such as **!thread** and **!teb** will still default to the current thread if no arguments are used with them.

Here is an example. Use the **!process** extension to find the address of the desired thread. (In this case, **!process 0 0** is used to list all processes, then **!process** is used a second time to list all the threads for the desired process.)

```
kd> !process 0 0
**** NT ACTIVE PROCESS DUMP ****
PROCESS fe5039e0 SessionId: 0 Cid: 0008 Peb: 00000000 ParentCid: 0000
  DirBase: 00030000 ObjectTable: fe529a88 TableSize: 145.
  Image: System

.....
PROCESS ffaa5280 SessionId: 0 Cid: 0120 Peb: 7ffd000 ParentCid: 01e0
  DirBase: 03b70000 ObjectTable: ffaa4e48 TableSize: 23.
  Image: winmine.exe

kd> !process ffaa5280
PROCESS ffaa5280 SessionId: 0 Cid: 0120 Peb: 7ffd000 ParentCid: 01e0
  DirBase: 03b70000 ObjectTable: ffaa4e48 TableSize: 23.
  Image: winmine.exe
  VadRoot ffaf6e48 Clone 0 Private 50. Modified 0. Locked 0.
  DeviceMap fe502e88
  Token           e1b55d70

.....
THREAD ffaa43a0 Cid 120.3a4 Peb: 7ffde000 Win32Thread: e1b4fea8 WAIT: (WrUserRequest) UserMode
Non-Alertable
  ffadc6a0 SynchronizationEvent
  Not impersonating
  Owning Process ffaa5280
  WaitTime (seconds) 24323
  Context Switch Count 494           LargeStack

.....
```

Now use the **.thread** command with the address of the desired thread. This sets the register context and enables you to examine the important registers and the call stack for this thread.

```
kd> .thread ffaa43a0
Using context of thread ffaa43a0

kd> r
Last set context:
eax=00000000 ebx=00000000 ecx=00000000 edx=00000000 esi=00000000 edi=00000000

[Send comments about this topic to Microsoft](#)

.time (Display System Time)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.time** command displays information about the system time variables.

```
.time [-h Hours]
```

Parameters

-h ** Hours**

Specifies the offset from Greenwich Mean Time, in hours. A negative value of *Hours* must be enclosed in parentheses.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

The system time variables control performance counter behavior.

Here is an example in kernel mode:

```
kd> .time
Debug session time: Wed Jan 31 14:47:08 2001
System Uptime: 0 days 2:53:56
```

Here is an example in user mode:

```
0:000> .time
Debug session time: Mon Apr 07 19:10:50 2003
System Uptime: 4 days 4:53:56.461
Process Uptime: 0 days 0:00:08.750
  Kernel time: 0 days 0:00:00.015
  User time: 0 days 0:00:00.015
```

[Send comments about this topic to Microsoft](#)

.tlist (List Process IDs)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.tlist** command lists all processes running on the system.

```
.tlist [Options][FileNamePattern]
```

Parameters

Options

Can be any number of the following options:

-v

Causes the display to be verbose. This includes the session number, the process user name, and the command-line used to start the process.

-c

Limits the display to just the current process.

FileNamePattern

Specifies the file name to be displayed, or a pattern that the file name of the process must match. Only those processes whose file names match this pattern will be displayed. *FileNamePattern* may contain a variety of wildcards and specifiers; see [String Wildcard Syntax](#) for details. This match is made only against the actual file name, not the path.

Environment

Modes	user mode only
Targets	live debugging only
Platforms	all

Additional Information

For other methods of displaying processes, see [Finding the Process ID](#).

Remarks

Each process ID is displayed with an **0n** prefix, to emphasize that the PID is a decimal number.

[Send comments about this topic to Microsoft](#)

.trap (Display Trap Frame)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.trap** command displays the trap frame register state and also sets the register context.

```
.trap [Address]
```

Parameters

Address

Hexadecimal address of the trap frame on the target system. Omitting the address does not display any trap frame information, but it does reset the register context.

Environment

Modes	kernel mode only
Targets	live, crash dump
Platforms	all

Additional Information

For more information about the register context and other context settings, see [Changing Contexts](#).

Remarks

The **.trap** command displays the important registers for the specified trap frame.

This command also instructs the kernel debugger to use the specified context record as the register context. After this command is executed, the debugger will have access to the most important registers and the stack trace for this thread. This register context persists until you allow the target to execute or use another register context command ([.thread](#), [.cxr](#), or [.trap](#)). See [Register Context](#) for full details.

This extension is commonly used when debugging bug check 0xA and 0x7F. For details and an example, see [Bug Check 0xA](#) (IRQL_NOT_LESS_OR_EQUAL).

[Send comments about this topic to Microsoft](#)

.tss (Display Task State Segment)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.tss** command displays a formatted view of the saved Task State Segment (TSS) information for the current processor.

```
.tss [Address]
```

Parameters

Address

Address of the TSS.

Environment

Modes	kernel mode only
Targets	live, crash dump
Platforms	x86 only

Remarks

The address of the TSS can be found by examining the output of the **!pcr** extension.

[Send comments about this topic to Microsoft](#)

.ttime (Display Thread Times)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.ttime** command displays the running times for a thread.

```
.ttime
```

Environment

Modes	user mode only
Targets	live, crash dump
Platforms	x86 only

Remarks

This command only works in user mode. In kernel mode you should use **!thread** instead. This command works with user-mode minidumps as long as they were created with the **/mt** or **/ma** options; see [Minidumps](#) for details.

The **.ttime** command shows the creation time of the thread, as well as the amount of time it has been running in kernel mode and in user mode.

Here is an example:

```
0:000> .ttime
Created: Sat Jun 28 17:58:42 2003
Kernel: 0 days 0:00:00.131
User: 0 days 0:00:02.109
```

[Send comments about this topic to Microsoft](#)

.typeopt (Set Type Options)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.typeopt** command sets or displays the type options.

```
.typeopt +Flags
.typeopt -Flags
.typeopt +FlagName
.typeopt -FlagName
.typeopt
```

Parameters

+

Causes the type options specified by *FlagName* to be set.

-

Causes the type options specified by *FlagName* to be cleared.

Flags

Specifies the type options to be changed. *FlagName* can be a sum of any of the following values (there is no default):

0x1

Displays values in all Watch windows and the Locals window as having UNICODE data type.

0x2

Displays values in all Watch windows and the Locals window as having LONG data type.

0x4

Displays integers in all Watch windows and the Locals window in the default radix.

0x8

Causes the debugger to choose the matching symbol with the largest size when the Locals window or Watch window references a symbol by name but there is more than one symbol that matches this name. The size of a symbol is defined as follows: if the symbol is the name of a function, its size is the size of the function in memory. Otherwise, the size of the symbol is the size of the data type that it represents.

FlagName

Specifies the type options to be changed. *FlagName* can be any one of the following strings (there is no default):

uni

Displays values in all Watch windows and the Locals window as having UNICODE data type. (This has the same effect as **0x1**.)

longst

Displays values in all Watch windows and the Locals window as having LONG data type. (This has the same effect as **0x2**.)

radix

Displays integers in all Watch windows and the Locals window in the default radix. (This has the same effect as **0x4**.)

size

Causes the debugger to choose the matching symbol with the largest size when the Locals window or Watch window references a symbol by name but there is more than one symbol that matches this name. The size of a symbol is defined as follows: if the symbol is the name of a function, its size is the size of the function in memory. Otherwise, the size of the symbol is the size of the data type that it represents. (This has the same effect as **0x8**.)

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

Without any arguments, **.typeopt** displays the current symbol options.

[Send comments about this topic to Microsoft](#)

.unload (Unload Extension DLL)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.unload** command unloads an extension DLL from the debugger.

```
.unload DLLName
!DLLName.unload
```

Parameters

DLLName

Specifies the file name of the debugger extension DLL to be unloaded. If the full path was specified when the DLL was loaded, it needs to be given in full here as well. If *DLLName* is omitted, the current extension DLL is unloaded.

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For more details on loading, unloading, and controlling extensions, see [Loading Debugger Extension DLLs](#).

Remarks

This command is useful when testing an extension you are creating. When the extension is recompiled, you must unload and then load the new DLL.

[Send comments about this topic to Microsoft](#)

.unloadall (Unload All Extension DLLs)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.unloadall** command unloads all extension DLLs from the debugger on the host system.

```
.unloadall
```

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For more details on loading, unloading, and controlling extensions, see [Loading Debugger Extension DLLs](#).

[Send comments about this topic to Microsoft](#)

.urestart (Unregister for Restart)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.urestart** command unregisters the debugging session for restart in case of a reboot or an application failure.

```
.urestart
```

Remarks

This command does not work for elevated debugger sessions.

See also

[.rrestart](#)

[Send comments about this topic to Microsoft](#)

.wake (Wake Debugger)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.wake** command causes sleep mode to end. This command is used only when you are controlling the user-mode debugger from the kernel debugger.

```
.wake PID
```

Parameters

PID

The process ID of the user-mode debugger.

Environment

Modes	controlling the user-mode debugger from the kernel debugger
Targets	live debugging only
Platforms	all

Additional Information

For more details, see [Controlling the User-Mode Debugger from the Kernel Debugger](#). For information about how to find the process ID of the debugger, see [Finding the Process ID](#).

Remarks

When you are controlling the user-mode debugger from the kernel debugger and the system is in sleep mode, this command can be used to wake up the debugger before the sleep timer runs out.

This command is not issued in the user-mode debugger on the target machine, nor in the kernel debugger on the host machine. It must be issued from a third debugger (KD, CDB, or NTSD) running on the target machine.

This debugger can be started expressly for this purpose, or can be another debugger that happens to be running. However, if there is no other debugger already running, it is easier just to use CDB with the [-wake command-line option](#).

[Send comments about this topic to Microsoft](#)

.write_cmd_hist (Write Command History)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.write_cmd_hist** command writes the entire history of the Debugger Command window to a file.

```
.write_cmd_hist Filename
```

Parameters

Filename

Specifies the path and filename of the file that will be created.

Environment

This command is available only in WinDbg and cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

[Send comments about this topic to Microsoft](#)

.writemem (Write Memory to File)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.writemem** command writes a section of memory to a file.

```
.writemem FileName Range
```

Parameters

FileName

Specifies the name of the file to be created. You can specify a full path and file name, or just the file name. If the file name contains spaces, *FileName* should be enclosed in quotation marks. If no path is specified, the current directory is used.

Range

Specifies the memory range to be written to the file. For syntax details, see [Address and Address Range Syntax](#).

Environment

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

The memory is copied literally to the file. It is not parsed in any way.

The **.writemem** command is the opposite of the [.readmem \(Read Memory from File\)](#) command.

[Send comments about this topic to Microsoft](#)

.wtitle (Set Window Title)

5/31/2017 • 1 min to read • [Edit Online](#)

The **.wtitle** command sets the title in the main WinDbg window or in the NTSD, CDB, or KD window.

```
.wtitle Title
```

Parameters

Title

The title to use for the window.

Environment

This command cannot be used in script files.

Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

For CDB, NTSD, or KD, if the **.wtitle** command has not been used, the window title matches the command line used to launch the debugger.

For WinDbg, if **.wtitle** has not been used, the main window title includes the name of the target. If a debugging server is active, its connection string is displayed as well. If multiple debugging servers are active, only the most recent one is displayed.

When **.wtitle** is used, *Title* replaces all this information. Even if a debugging server is started later, *Title* will not change.

The WinDbg version number is always displayed in the window title bar, regardless of whether this command is used.

[Send comments about this topic to Microsoft](#)

Control Keys

5/26/2017 • 1 min to read • [Edit Online](#)

This section of the reference discusses the various control keys that can be used in the debuggers.

These control keys work in KD and, in some cases, CDB. Many of these also work in WinDbg (using the CTRL+ALT keys instead of just CTRL).

WinDbg also uses the CTRL key, the ALT key, and the F keys as shortcut keys to toggle the menu options. See [Shortcut Keys](#) for a list of their meanings.

[Send comments about this topic to Microsoft](#)

CTRL+\ (Debug Current Debugger)

5/31/2017 • 1 min to read • [Edit Online](#)

The **CTRL+** key launches a new instance of CDB; this new debugger takes the current debugger as its target.

CTRL+\ ENTER

Environment

Debuggers	CDB, NTSD, KD
Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

This is equivalent to launching a new CDB through the [remote.exe](#) utility, and using it to debug the debugger that you are already running.

CTRL+ is similar to the [.dbgdbg \(Debug Current Debugger\)](#) command.

[Send comments about this topic to Microsoft](#)

CTRL+ALT+\ (Debug Current Debugger)

5/31/2017 • 1 min to read • [Edit Online](#)

The **CTRL+ALT+** key launches a new instance of CDB; this new debugger takes the current debugger as its target.

CTRL+ALT+\

Environment

Debuggers	WinDbg
Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

This is equivalent to launching a new CDB through the [remote.exe](#) utility, and using it to debug the debugger that you are already running.

CTRL+ALT+ is similar to the [.dbgdbg \(Debug Current Debugger\)](#) command, however **CTRL+ALT+** has the advantage that it can be used when no debugger command line is available.

[Send comments about this topic to Microsoft](#)

CTRL+A (Toggle Baud Rate)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+A key toggles the baud rate used in the kernel debugging connection.

KD Syntax

```
CTRL+A  ENTER
```

WinDbg Syntax

```
CTRL+ALT+A
```

Environment

Debuggers	KD and WinDbg only
Modes	kernel mode only
Targets	live debugging only
Platforms	all

Remarks

This will cycle through all available baud rates for the kernel debugging connection.

Supported baud rates are 19200, 38400, 57600, and 115200. Each time this control key is used, the next baud rate will be selected. If the baud rate is already at 115200, it will be reduced to 19200.

In WinDbg, this can also be accomplished by selecting [Debug | Kernel Connection | Cycle Baud Rate](#).

You cannot actually use this control key to change the baud rate at which you are debugging. The baud rate of the host computer and the target computer must match, and the baud rate of the target computer cannot be changed without rebooting. Therefore, you only need to toggle through the baud rates if the two computers are attempting to communicate at different rates. In this case, you must change the host computer's baud rate to match that of the target computer.

[Send comments about this topic to Microsoft](#)

CTRL+B (Quit Local Debugger)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+B key causes the debugger to terminate abruptly. This does not end a remote debugging session.

CTRL+B ENTER

Environment

Debuggers	CDB and KD only
Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

In CDB, the [q \(Quit\)](#) command should be used to exit. CTRL+B should only be used if the debugger is not responding.

In KD, the [q](#) command will end the debugging session and leave the target computer locked. If you need to preserve the debugging session (so a new debugger can connect to it), or if you need to leave the target computer running, you should use CTRL+B.

In WinDbg, the equivalent command is [File | Exit](#) or ALT+F4.

[Send comments about this topic to Microsoft](#)

CTRL+C (Break)

5/31/2017 • 2 min to read • [Edit Online](#)

The CTRL+C key breaks into the debugger, stopping the target application or target computer, and cancels debugger commands.

CDB Syntax

```
CTRL+C
```

KD Syntax

```
CTRL+C
```

Target Computer Syntax

```
SYSRQ  
ALT+SYSRQ  
F12
```

Environment

Debuggers	CDB and KD only
Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Additional Information

For other methods of issuing this command and an overview of related commands, see [Controlling the Target](#).

Remarks

When Using CDB:

In user mode, the CTRL+C key causes the target application to break into the debugger. The target application freezes, the debugger becomes active, and debugger commands can be entered.

If the debugger is already active, CTRL+C does not affect the target application. It can be, however, used to terminate a debugger command. For instance, if you have requested a long display and no longer want to see it, CTRL+C will end the display and return you to the debugger command prompt.

When performing remote debugging with CDB, CTRL+C can be pressed on the host computer's keyboard. If you want to issue a break from the target computer's keyboard, use CTRL+C on an x86 machine.

The F12 key can be used to get a command prompt when the application being debugged is busy. Set the focus on one of the target application's windows and press the F12 key on the target computer.

When Using KD:

In kernel mode, the CTRL+C key causes the target computer to break into the debugger. This locks the target computer and wakes up the debugger.

When debugging a system that is still running, CTRL+C must be pressed on the host keyboard to get the initial command prompt.

If the debugger is already active, CTRL+C does not affect the target computer. It can be used, however, to terminate a debugger command. For instance, if you have requested a long display and no longer want to see it, CTRL+C will end the display and return you to the debugger command prompt.

CTRL+C can also be used to get a command prompt when a debugger command is generating a long display or when the target computer is busy. When debugging an x86 machine, it can be pressed on either the host or target keyboard.

SYSRQ (or ALT+SYSRQ on an enhanced keyboard) is similar. It works from the host or target keyboard on any processor. However, it only works if the prompt has been acquired by pressing CTRL+C at least once before.

The SYSRQ key can be disabled by editing the registry. In the registry key

```
HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\i8042prt\Parameters
```

create a value named **BreakOnSysRq**, and set it equal to DWORD 0x0. Then reboot. After this is done, pressing the SYSRQ key on the target computer's keyboard will not break into the kernel debugger.

When Debugging KD with CDB:

If you are debugging KD with CDB, then CTRL+C will be intercepted by the host debugger (CDB). To break into the target debugger (KD), you should use **CTRL+F** instead.

Note Note that in WinDbg, CTRL+C is a [shortcut key](#) that is used to copy text from a window. To issue a break command in WinDbg, use **CTRL+BREAK** or select Debug | Break from the menu.

[Send comments about this topic to Microsoft](#)

CTRL+D (Toggle Debug Info)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+D key toggles debugger internal information flow on and off. This is used to restart communication between the target computer and the host computer in cases where the debugger is not communicating properly.

KD Syntax

```
CTRL+D  ENTER
```

WinDbg Syntax

```
CTRL+ALT+D
```

Environment

Debuggers	KD and WinDbg only
Modes	kernel mode only
Targets	live debugging only
Platforms	all

Remarks

When this is toggled on, the debugger outputs information about the communication between the host computer and the target computer.

This key can be used to test whether the debugger has crashed. If you suspect that either the debugger or the target is frozen, use this key. If you see packets being sent, the target is still working. If you see time-out messages, then the target is not responding. If there are no messages at all, the debugger has crashed.

If the target is not responding, use CTRL+R ENTER CTRL+C. If time-out messages continue to appear, the target has crashed (or the debugger was misconfigured).

This is also useful for debugging the KD debugger itself.

[Send comments about this topic to Microsoft](#)

CTRL+F (Break to KD)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+F key cancels commands or breaks into the debugger. (This control key is particularly useful when you are using CDB to debug KD itself.)

CTRL+F ENTER

Environment

Debuggers	CDB, KD
Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

Under typical conditions, CTRL+F is identical to the standard break commands ([CTRL+C](#) in KD and CDB, and [Debug | Break](#) or [CTRL+BREAK](#) in WinDbg.)

However, if you are debugging KD with CDB, these two keys will work differently. CTRL+C will be intercepted by the host debugger (CDB), while CTRL+F will be intercepted by the target debugger (KD).

See also

[.breakin \(Break to the Kernel Debugger\)](#)

[Send comments about this topic to Microsoft](#)

CTRL+K (Change Post-Reboot Break State)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+K key changes the conditions on which the debugger will automatically break into the target computer.

KD Syntax

```
CTRL+K  ENTER
```

WinDbg Syntax

```
CTRL+ALT+K
```

Environment

Debuggers	KD and WinDbg only
Modes	kernel mode only
Targets	live debugging only
Platforms	all

Additional Information

For an overview of related commands and an explanation of how the reboot process affects the debugger, see [Crashing and Rebooting the Target Computer](#).

Remarks

This control key causes the kernel debugger to cycle through the following three states:

No break

In this state, the debugger will not break into the target computer unless you press [CTRL+C](#).

Break on reboot

In this state, the debugger will break into a rebooted target computer after the kernel initializes. This is equivalent to starting KD or WinDbg with the [-bcommand-line option](#).

Break on first module load

In this state, the debugger will break into a rebooted target computer after the first kernel module is loaded. (This will cause the break to occur earlier than in the **Break on reboot** option.) This is equivalent to starting KD or WinDbg with the [-dcommand-line option](#).

When CTRL+K is used, the new break state is displayed.

In WinDbg, this can also be accomplished by selecting [Debug | Kernel Connection | Cycle Initial Break](#).

[Send comments about this topic to Microsoft](#)

CTRL+P (Debug Current Debugger)

5/26/2017 • 1 min to read • [Edit Online](#)

The **CTRL+P** command is obsolete and has been replaced by [CTRL+\](#) and [CTRL+ALT+\](#).

[Send comments about this topic to Microsoft](#)

CTRL+R (Re-synchronize)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+R key synchronizes with the target computer.

KD Syntax

```
CTRL+R  ENTER
```

WinDbg Syntax

```
CTRL+ALT+R
```

Environment

Debuggers	KD and WinDbg only
Modes	kernel mode only
Targets	live debugging only
Platforms	all

Additional Information

For other methods of re-establishing contact with the target, see [Synchronizing with the Target Computer](#).

Remarks

This attempts to synchronize the host computer with the target computer. Use this key if the target is not responding.

If you are using a 1394 kernel connection, resynchronization may not always be successful.

[Send comments about this topic to Microsoft](#)

CTRL+V (Toggle Verbose Mode)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+V key toggles verbose mode on and off.

CDB / KD Syntax

```
CTRL+V  ENTER
```

WinDbg Syntax

```
CTRL+ALT+V
```

Environment

Debuggers	CDB, KD, WinDbg
Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

When verbose mode is turned on, some display commands (such as register dumping) produce more detailed output. Every MODULE LOAD operation that is sent to the debugger will be displayed. And every time a driver or DLL is loaded by the operating system, the debugger will be notified.

In WinDbg, this can also be accomplished by selecting [View | Verbose Output](#).

[Send comments about this topic to Microsoft](#)

CTRL+W (Show Debugger Version)

5/31/2017 • 1 min to read • [Edit Online](#)

The CTRL+W key displays version information for the debugger and all loaded extension DLLs.

CDB / KD Syntax

```
CTRL+W  ENTER
```

WinDbg Syntax

```
CTRL+ALT+W
```

Environment

Debuggers	CDB, KD, WinDbg
Modes	user mode, kernel mode
Targets	live, crash dump
Platforms	all

Remarks

This has the same effect as the [version \(Show Debugger Version\)](#) command, except that the latter command displays the Windows operating system version as well.

In WinDbg, this can also be accomplished by selecting [View | Show Version](#).

See also

[version \(Show Debugger Version\)](#)

[vertarget \(Show Target Computer Version\)](#)

[Send comments about this topic to Microsoft](#)

General Extensions

5/26/2017 • 1 min to read • [Edit Online](#)

This section describes extension commands that are frequently used during both user-mode and kernel-mode debugging.

The debugger automatically loads the proper version of these extension commands. Unless you have manually loaded a different version, you do not have to keep track of the DLL versions that are being used. For more information about the default module search order, see [Using Debugger Extension Commands](#). For more information about how to load extension modules, see [Loading Debugger Extension DLLs](#).

Each extension command reference topics lists the DLLs that expose that command. Use the following rules to determine the proper directory to load this extension DLL from:

- If your target computer is running Microsoft Windows XP or a later version of Windows, use winxp\kdexts.dll, winxp\ntsdexts.dll, winxp\exts.dll, winext\ext.dll, or dbghelp.dll.

[Send comments about this topic to Microsoft](#)

!acl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!acl** extension formats and displays the contents of an access control list (ACL).

Syntax

```
!acl Address [Flags]
```

Parameters

Address

Specifies the hexadecimal address of the ACL.

Flags

Displays the friendly name of the ACL, if the value of *Flags* is 1. This friendly name includes the security identifier (SID) type and the domain and user name for the SID.

DLL

Exts.dll

Additional Information

For more information about access control lists, see [!sid](#), [!sd](#), and [Determining the ACL of an Object](#). Also, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

The following example shows the **!acl** extension.

```
kd> !acl e1bf35d4 1
ACL is:
ACL is: ->AclRevision: 0x2
ACL is: ->Sbz1      : 0x0
ACL is: ->AclSize    : 0x40
ACL is: ->AceCount   : 0x2
ACL is: ->Sbz2      : 0x0
ACL is: ->Ace[0]: ->AceType: ACCESS_ALLOWED_ACE_TYPE
ACL is: ->Ace[0]: ->AceFlags: 0x0
ACL is: ->Ace[0]: ->AceSize: 0x24
ACL is: ->Ace[0]: ->Mask : 0x10000000
ACL is: ->Ace[0]: ->SID: S-1-5-21-518066528-515770016-299552555-2981724 (User: MYDOMAIN\myuser)

ACL is: ->Ace[1]: ->AceType: ACCESS_ALLOWED_ACE_TYPE
ACL is: ->Ace[1]: ->AceFlags: 0x0
ACL is: ->Ace[1]: ->AceSize: 0x14
ACL is: ->Ace[1]: ->Mask : 0x10000000
ACL is: ->Ace[1]: ->SID: S-1-5-18 (Well Known Group: NT AUTHORITY\SYSTEM)
```

[Send comments about this topic to Microsoft](#)

!address

5/31/2017 • 5 min to read • [Edit Online](#)

The **!address** extension displays information about the memory that the target process or target computer uses.

User-Mode

```
!address Address
!address -summary
!address [-f:F1,F2,...] {[-o:{csv | tsv | 1}] | [-c:"Command"]}
!address -? | -help
```

Kernel-Mode

```
!address Address
!address
```

Parameters

Address

Displays only the region of the address space that contains *Address*.

-summary

Displays only summary information.

-f:F1, F2, ...

Displays only the regions specified by the filters *F1*, *F2*, and so on.

The following filter values specify memory regions by the way that the target process is using them.

FILTER VALUE	MEMORY REGIONS DISPLAYED
VAR	Busy regions. These regions include all virtual allocation blocks, the SBH heap, memory from custom allocators, and all other regions of the address space that fall into no other classification.
Free	Free memory. This includes all memory that has not been reserved.
Image	Memory that is mapped to a file that is part of an executable image.
Stack	Memory used for thread stacks.
Teb	Memory used for thread environment blocks (TEBs).

FILTER VALUE	MEMORY REGIONS DISPLAYED
Peb	Memory used for the process environment block (PEB).
Heap	Memory used for heaps.
PageHeap	The memory region used for the full-page heap.
CSR	CSR shared memory.
Actx	Memory used for activation context data.
NLS	Memory used for National Language Support (NLS) tables.
FileMap	Memory used for memory-mapped files. This filter is applicable only during live debugging.

The following filter values specify memory regions by the memory type.

FILTER VALUE	MEMORY REGIONS DISPLAYED
MEM_IMAGE	Memory that is mapped to a file that is part of an executable image.
MEM_MAPPED	Memory that is mapped to a file that is not part of an executable image. This includes memory that is mapped to the paging file.
MEM_PRIVATE	Private memory. This memory is not shared by any other process, and it is not mapped to any file.

The following filter values specify memory regions by the state of the memory.

FILTER VALUE	MEMORY REGIONS DISPLAYED
MEM_COMMIT	Committed memory.
MEM_FREE	Free memory. This includes all memory that has not been reserved.
MEM_RESERVE	Reserved memory.

The following filter values specify memory regions by the protection applied to the memory.

FILTER VALUE	MEMORY REGIONS DISPLAYED
PAGE_NOACCESS	Memory that cannot be accessed.
PAGE_READONLY	Memory that is readable, but not writable and not executable.
PAGE_READWRITE	Memory that is readable and writable, but not executable.
PAGE_WRITECOPY	Memory that has copy-on-write behavior.
PAGE_EXECUTE	Memory that is executable, but not readable and not writeable.
PAGE_EXECUTE_READ	Memory that is executable and readable, but not writable.
PAGE_EXECUTE_READWRITE	Memory that is executable, readable, and writable.
PAGE_EXECUTE_WRITECOPY	Memory that is executable and has copy-on-write behavior.
PAGE_GUARD	Memory that acts as a guard page.
PAGE_NOCACHE	Memory that is not cached.
PAGE_WRITECOMBINE	Memory that has write-combine access enabled.

-o:{csv | tsv | 1}

Displays the output according to one of the following options.

OPTION	OUTPUT FORMAT
csv	Displays the output as comma-separated values.
tsv	Displays the output as tab-separated values.
1	Displays the output in bare format. This format works well when !address is used as input to .foreach .

-c:"Command"

Executes a custom command for each memory region. You can use the following placeholders in your command to represent output fields of the **!address** extension.

PLACEHOLDER	OUTPUT FIELD
%1	Base address
%2	End address + 1
%3	Region size
%4	Type
%5	State
%6	Protection
%7	Usage

For example, `!address -f:Heap -c:".echo %1 %3 %5"` displays the base address, size, and state for each memory region of type **Heap**.

Quotes in the command must be preceded by a back slash (\"). For example, `!address -f:Heap -c:"s -a %1 %2 \\"pad\\\""` searches each memory region of type **Heap** for the string "pad".

Multiple commands separated by semicolons are not supported.

-?

Displays minimal Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about how to display and search memory, see [Reading and Writing Memory](#). For additional extensions that display memory properties, see [!vmm](#) (kernel mode) and [!vprot](#) (user mode).

Remarks

Without any parameters, the **!address** extension displays information about the whole address space. The **!address -summary** command shows only the summary.

In kernel mode, this extension searches only kernel memory, even if you used [.process \(Set Process Context\)](#) to specify a given process' virtual address space. In user mode, the **!address** extension always refers to the memory that the target process owns.

In user mode, **!address Address** shows the characteristics of the region that the specified address belongs to. Without parameters, **!address** shows the characteristics of all memory regions. These characteristics include the memory usage, memory type, memory state, and memory protection. For more information about the meaning of

this information, see the earlier tables in the description of the **-f** parameter.

The following example uses **!address** to retrieve information about a region of memory that is mapped to kernel32.dll.

```
0:000> !address 75831234
Usage:           Image
Base Address:    75831000
End Address:    758f6000
Region Size:    000c5000
Type:            01000000MEM_IMAGE
State:           00001000MEM_COMMIT
Protect:         00000020PAGE_EXECUTE_READ
More info:       !lmv m kernel32
More info:       !lmi kernel32
More info:       ln 0x75831234
```

This example uses an *Address* value of 0x75831234. The display shows that this address is in a memory region that begins with the address 0x75831000 and ends with the address 0x758f6000. The region has usage **Image**, type **MEM_IMAGE**, state **MEM_COMMIT**, and protection **PAGE_EXECUTE_READ**. (For more information about the meaning of these values, see the earlier tables.) The display also lists three other debugger commands that you can use to get more information about this memory address.

If you are starting with an address and trying to determine information about it, the usage information is frequently the most valuable. After you know the usage, you can use additional extensions to learn more about this memory. For example, if the usage is **Heap**, you can use the **!heap** extension to learn more.

The following example uses the **s (Search Memory)** command to search each memory region of type **Image** for the wide-character string "Note".

```
!address /f:Image /c:"s -u %1 %2 \"Note\""
*** Executing: s -u 0xab0000 0xab1000 "Note"
*** Executing: s -u 0xab1000 0xabc000 "Note"
00ab2936 004e 006f 0074 0065 0070 0061 0064 0000 N.o.t.e.p.a.d...
00ab2f86 004e 006f 0074 0065 0070 0061 0064 005c N.o.t.e.p.a.d.\.
00ab32e4 004e 006f 0074 0065 0070 0061 0064 0000 N.o.t.e.p.a.d...
*** Executing: s -u 0abc000 0abd000 "Note"
...
...
```

In kernel mode, the output of **!address** is similar to the user mode output but contains less information. The following example shows the kernel mode output.

```
kd> !address
804de000 - 00235000
Usage      KernelSpaceUsageImage
ImageName  ntoskrnl.exe

80c00000 - 001e1000
Usage      KernelSpaceUsagePFNDatabase

...
f85b0000 - 00004000
Usage      KernelSpaceUsageKernelStack
KernelStack 817b4da0 : 324.368

f880d000 - 073d3000
Usage      KernelSpaceUsageNonPagedPoolExpansion
```

The meaning of "usage" is the same as in user mode. "ImageName" indicates the module that is associated with this address. "KernelStack" shows the address of this thread'sETHREAD block (0x817B4DA0), the process ID (0x324), and the thread ID (0x368).

[Send comments about this topic to Microsoft](#)

!analyze

5/31/2017 • 2 min to read • [Edit Online](#)

The **!analyze** extension displays information about the current exception or bug check.

User-Mode

```
!analyze [-v] [-f | -hang] [-D BucketID]
!analyze -c [-load KnownIssuesFile | -unload | -help ]
```

Kernel-Mode

```
!analyze [-v] [-f | -hang] [-D BucketID]
!analyze -c [-load KnownIssuesFile | -unload | -help ]
!analyze -show BugCheckCode [BugParameters]
```

Parameters

-v

Displays verbose output.

-f

Generates the **!analyze** exception output. Use this parameter to see an exception analysis even when the debugger does not detect an exception.

-hang

Generates **!analyze** hung-application output. Use this parameter when the target has experienced a bug check or exception, but an analysis of why an application hung is more relevant to your problem. In kernel mode, **!analyze -hang** investigates locks that the system holds and then scans the DPC queue chain. In user mode, **!analyze -hang** analyzes the thread stack to determine whether any threads are blocking other threads.

Before you run this extension in user mode, consider changing the current thread to the thread that you think has stopped responding (that is, hung), because the exception might have changed the current thread to a different one.

-D BucketID

Displays only those items that are relevant to the specified *BucketID*.

-show BugCheckCode [BugParameters]

Displays information about the bug check specified by *BugCheckCode*. *BugParameters* specifies up to four bug check parameters separated by spaces. These parameters enable you to further refine your search.

-c

Continues execution when the debugger encounters a known issue. If the issue is not a "known" issue, the debugger remains broken into the target.

You can use the **-c** option with the following subparameters. These subparameters configure the list of known issues. They do not cause execution to occur by themselves. Until you run **!analyze -c *****

-load at least one time, **!analyze -c** has no effect.

-load *KnownIssuesFile*

Loads the specified known-issues file. *KnownIssuesFile* specifies the path and file name of this file. This file must be in XML format. You can find a sample file in the `sdk\samples\analyze_continue` subdirectory of the debugger installation directory. (You must have performed a full installation of Debugging Tools for Windows to have this file.)

The list of known issues in the *KnownIssuesFile* file is used for all later **-c** commands until you use **-c **** -unload**, or until you use **-c **** -load** again (at which point the new data replaces the old data).

-unload

Unloads the current list of known issues.

-help

Displays help for the **!analyze -c** extension commands extension in the [Debugger Command window](#).

DLL

Ext.dll

Additional Information

For sample analysis of a user-mode exception and of a kernel-mode stop error (that is, crash), and for more information about how **!analyze** uses the `trage.ini` file, see [Using the !analyze Extension](#).

Remarks

In user mode, **!analyze** displays information about the current exception.

In kernel mode, **!analyze** displays information about the most recent bug check. If a bug check occurs, the **!analyze** display is automatically generated. You can use **!analyze -v** to show additional information. If you want to see only the basic bug check parameters, you can use the [.bugcheck \(Display Bug Check Data\)](#) command.

For drivers that use User-Mode Driver Framework (UMDF) version 2.15 or later, **!analyze** provides information about UMDF verifier failures and unhandled exceptions. This functionality is available when performing live kernel-mode debugging, as well when analyzing a user-mode memory dump file. For UMDF driver crashes, **!analyze** attempts to identify the responsible driver.

[Send comments about this topic to Microsoft](#)

!asd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!asd** extension displays a specified number of failure analysis entries from the data cache, starting at the specified address.

```
!asd Address DataUsed
```

Parameters

Address

Specifies the address of the first failure analysis entry to display.

DataUsed

Determines the number of tokens to display.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

You can use the [!dumpfa](#) extension to debug the [!analyze](#) extension.

Remarks

The **!asd** extension is useful only when you are debugging the [!analyze](#) extension.

[Send comments about this topic to Microsoft](#)

!atom

5/31/2017 • 1 min to read • [Edit Online](#)

The **!atom** extension displays the formatted atom table for the specified atom or for all atoms of the current process.

```
!atom [Address]
```

Parameters

Address

Specifies the hexadecimal virtual address of the atom to display. If you omit this parameter or specify zero, the atom table for the current process is displayed. This table lists all atoms for the process.

DLL

Windows 2000	Kdextx86.dll Ntsdexts.dll
Windows XP and later	Exts.dll

Additional Information

For more information about atoms and atom tables, see the Microsoft Windows SDK documentation.

[Send comments about this topic to Microsoft](#)

!bitcount

5/31/2017 • 1 min to read • [Edit Online](#)

The **!bitcount** extension counts the number of "1" bits in a memory range.

```
!bitcount StartAddress TotalBits
```

Parameters

StartAddress

Specifies the starting address of the memory range whose "1" bits will be counted.

TotalBits

Specifies the size of the memory range, in bits.

-?

Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Unavailable
Windows XP and later	Exts.dll

[Send comments about this topic to Microsoft](#)

!chksym

5/31/2017 • 1 min to read • [Edit Online](#)

The **!chksym** extension tests the validity of a module against a symbol file.

```
!chksym Module [Symbol]
```

Parameters

Module

Specifies the name of the module by its name or base address.

Symbol

Specifies the name of a symbol file.

DLL

Windows 2000	Unavailable
Windows XP	Unavailable
Windows Vista and later	Dbghelp.dll

Remarks

If you do not specify a symbol file, the loaded symbol is tested. Otherwise, if you specify a .pdb or .dbg symbol file path, the loaded symbol is tested against the loaded module.

[Send comments about this topic to Microsoft](#)

!chkimg

5/31/2017 • 9 min to read • [Edit Online](#)

The **!chkimg** extension detects corruption in the images of executable files by comparing them to the copy on a symbol store or other file repository.

```
!chkimg [Options] [-mmw LogFile LogOptions] [Module]
```

Parameters

Options

Any combination of the following options:

-p **** *SearchPath*

Recursively searches *SearchPath* for the file before accessing the symbol server.

-f

Fixes errors in the image. Whenever the scan detects differences between the file on the symbol store and the image in memory, the contents of the file on the symbol store are copied over the image. If you are performing live debugging, you can create a dump file before you execute the **!chkimg -f** extension.

-nar

Prevents the mapped image of the file on the symbol server from being moved. By default, when the copy of the file is located on the symbol server and mapped into memory, **!chkimg** moves the image of the file on the symbol server. However, if you use the **-nar** option, the image of the file from the server is not moved.

The executable image that is already in memory (that is, the one that is being scanned) is moved, because the debugger always relocates images that it loads.

This switch is useful only if the operating system already moved the original image. If the image has not been moved, **!chkimg** and the debugger will move the image. Use of this switch is rare.

-ss **** *SectionName*

Limits the scan to those sections whose names contain the string *SectionName*. The scan will include any non-discardable section whose name contains this string. *SectionName* is case sensitive and cannot exceed 8 characters.

-as

Causes the scan to include all sections of the image except discardable sections. By default, (if you do not use **-as** or **-ss**), the scan skips sections that are writeable, sections that are not executable, sections that have "PAGE" in their name, and discardable sections.

-r **** *StartAddress* **** *EndAddress*

Limits the scan to the memory range that begins with *StartAddress* and ends with *EndAddress*. Within this range, any sections that would typically be scanned are scanned. If a section partially overlaps with this range, only that part of the section that overlaps with this range is scanned. The scan is limited to this range even if you also use the **-as** or **-ss** switch.

-nospec

Causes the scan to include the reserved sections of Hal.dll and Ntoskrnl.exe. By default, **!chkimg** does not check certain parts of these files.

-noplock

Displays areas that mismatch by having a byte value of 0x90 (a **nop** instruction) and a byte value of 0xF0 (a **lock** instruction). By default, these mismatches are not displayed.

-np

Causes patched instructions to be recognized.

-d

Displays a summary of all mismatched areas while the scan is occurring. For more information about this summary text, see the Remarks section.

-db

Displays mismatched areas in a format that is similar to the **db debugger command**. Therefore, each display line shows the address of the first byte in the line, followed by up to 16 hexadecimal byte values. The byte values are immediately followed by the corresponding ASCII values. All nonprintable characters, such as carriage returns and line feeds, are displayed as periods (.). The mismatched bytes are marked by an asterisk (*).

-lo ** lines**

Limits the number of output lines that **-d** or **-db** display to the lines number of lines.

-v

Displays verbose information.

-mmw

Creates a log file and records the activity of **!chkimg** in this file. Each line of the log file represents a single mismatch.

LogFile

Specifies the full path of the log file. If you specify a relative path, the path is relative to the current path.

LogOptions

Specifies the contents of the log file. *LogOptions* is a string that consists of a concatenation of various letters. Each line in the log file contains several columns that are separated by commas. These columns include the items that the following option letters specify, in the order that the letters appear in the *LogOptions* string. You can include the following options multiple times. You must include at least one option.

LOG OPTION	INFORMATION INCLUDED IN THE LOG FILE
v	The virtual address of the mismatch
r	The offset (relative address) of the mismatch within the module
s	The symbol that corresponds to the address of the mismatch
S	The name of the section that contains the mismatch
e	The correct value that was expected at the mismatch location
w	The incorrect value that was at the mismatch location

LogOptions can also include some, or none, of the following additional options.

LOG OPTION	EFFECT
o	If a file that has the name <i>LogFile</i> already exists, the existing file is overwritten. By default, the debugger appends new information to the end of any existing file.
<i>tString</i>	Adds an extra column to the log file. Each entry in this column contains <i>String</i> . The <i>tString</i> option is useful if you are appending new information to an existing log file and you have to distinguish the new records from the old. You cannot add space between <i>t</i> and <i>String</i> . If you use the <i>tlString</i> option, it must be the final option in <i>LogOptions</i> , because <i>String</i> is taken to include all of the characters that are present before the next space.

For example, if *LogOptions* is **rSewo**, each line of the log file contains the relative address and section name of the mismatch location and the expected and actual values at that location. This option also causes any previous file to be overwritten. You can use the **-mmw** switch multiple times if you want to create several log files that have different options. You can create up to 10 log files at the same time.

Module

Specifies the module to check. *Module* can be the name of the module, the starting address of the module, or any address that is contained in the module. If you omit *Module*, the debugger uses the module that contains the current instruction pointer.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

When you use **!chkimg**, it compares the image of an executable file in memory to the copy of the file that resides on a symbol store.

All sections of the file are compared, except for sections that are discardable, that are writeable, that are not executable, that have "PAGE" in their name, or that are from INITKDBG. You can change this behavior can by using the **-ss**, **-as**, or **-r** switches.

!chkimg displays any mismatch between the image and the file as an image error, with the following exceptions:

- Addresses that are occupied by the Import Address Table (IAT) are not checked.
- Certain specific addresses in Hal.dll and Ntoskrnl.exe are not checked, because certain changes occur when these sections are loaded. To check these addresses, include the **-nospec** option.
- If the byte value 0x90 is present in the file, and if the value 0xF0 is present in the corresponding byte of the image (or vice versa), this situation is considered a match. Typically, the symbol server holds one version of a binary that exists in both uniprocessor and multiprocessor versions. On an x86-based processor, the **lock** instruction is 0xF0, and this instruction corresponds to a **nop** (0x90) instruction in the uniprocessor version. If you want **!chkimg** to display this pair as a mismatch, set the **-noplock** option.

Note If you use the **-f** option to fix image mismatches, **!chkimg** fixes only those mismatches that it considers to be errors. For example, **!chkimg** does not change an 0x90 byte to an 0xF0 byte unless you include **-noplock**.

When you include the **-d** option, **!chkimg** displays a summary of all mismatched areas while the scan is occurring. Each mismatch is displayed on two lines. The first line includes the start of the range, the end of the range, the size of the range, the symbol name and offset that corresponds to the start of the range, and the number of bytes since the last error (in parentheses). The second line is enclosed in brackets and includes the hexadecimal byte values that were expected, a colon, and then the hexadecimal byte values that were actually encountered in the image. If the range is longer than 8 bytes, only the first 8 bytes are shown before the colon and after the colon. The following example shows this situation.

```
be000015-be000016 2 bytes - win32k!VeryUsefulFunction+15 (0x8)
[ 85 dd:95 23 ]
```

Occasionally, a driver alters part of the Microsoft Windows kernel by using hooks, redirection, or other methods. Even a driver that is no longer on the stack might have altered part of the kernel. You can use the **!chkimg** extension as a file comparison tool to determine which parts of the Windows kernel (or any other image) are being altered by drivers and exactly how the parts are being changed. This comparison is most effective on full dump files.

You can also use **!chkimg** together with the **!for_each_module** extension to check the image of each loaded module. The following example shows this situation.

```
!for_each_module !chkimg @#ModuleName
```

Suppose that you encounter a bug check, for example, and begin by using **!analyze**.

```
kd> !analyze
...
BugCheck 1000008E, {c0000005, bf920e48, baf75b38, 0}
Probably caused by : memory_corruption
CHKIMG_EXTENSION: !chkimg !win32k
...
```

In this example, the **!analyze** output suggests that memory corruption has occurred and includes a **CHKIMG_EXTENSION** line that suggests that Win32k.sys could be the corrupted module. (Even if this line is not present, you might consider possible corruption in the module on top of the stack.) Start by using **!chkimg** without any switches, as the following example shows.

```
kd> !chkimg win32k
Number of different bytes for win32k: 31
```

The following example shows that there are indeed memory corruptions. Use **!chkimg -d** to display all of the errors for the Win32k module.

```
kd> !chkimg win32k -d
bf920e40-bf920e46 7 bytes - win32k!HFDBASIS32::vSteadyState+1f
[ 78 08 d3 78 0c c2 04:00 00 00 00 00 01 00 ]
bf920e48-bf920e5f 24 bytes - win32k!HFDBASIS32::vHalveStepSize (+0x08)
[ 8b 51 0c 8b 41 08 56 8b:00 00 00 00 00 00 00 00 ]
Number of different bytes for win32k: 31
```

When you try to disassemble the corrupted image of the second section that is listed, the following output might occur.

```
kd> u win32k!HFDBASIS32::vHalveStepSize
win32k!HFDBASIS32::vHalveStepSize:
bf920e48 0000      add    [eax],al
bf920e4a 0000      add    [eax],al
bf920e4c 0000      add    [eax],al
bf920e4e 0000      add    [eax],al
bf920e50 7808      js    win32k!HFDBASIS32::vHalveStepSize+0x12 (bf920e5a)
bf920e52 d3780c      sar    dword ptr [eax+0xc],cl
bf920e55 c20400      ret    0x4
bf920e58 8b510c      mov    edx,[ecx+0xc]
```

Then, use **!chkimg -f** to fix the memory corruption.

```
kd> !chkimg win32k -f
Warning: Any detected errors will be fixed to what we expect!
Number of different bytes for win32k: 31 (fixed)
```

Now you can disassemble the corrected view and see the changes that you have made.

```
kd> u win32k!HFDBASIS32::vHalveStepSize
win32k!HFDBASIS32::vHalveStepSize:
bf920e48 8b510c      mov    edx,[ecx+0xc]
bf920e4b 8b4108      mov    eax,[ecx+0x8]
bf920e4e 56          push   esi
bf920e4f 8b7104      mov    esi,[ecx+0x4]
bf920e52 03c2          add    eax,edx
bf920e54 c1f803      sar    eax,0x3
bf920e57 2bf0          sub    esi,eax
bf920e59 d1fe          sar    esi,1
```

[Send comments about this topic to Microsoft](#)

!cppexpr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!cppexpr** extension displays the contents of a C++ exception record.

`!cppexpr Address`

Parameters

Address

Specifies the address of the C++ exception record to display.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about exceptions, see [Controlling Exceptions and Events](#), the Windows Driver Kit (WDK) documentation, the Windows SDK documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.) Use the [.exr](#) command to display other exception records.

Remarks

The **!cppexpr** extension displays information that is related to a C++ exception that the target encounters, including the exception code, the address of the exception, and the exception flags. This exception must be one of the standard C++ exceptions that are defined in `Msvcrtdll`.

You can typically obtain the *Address* parameter by using the [!analyze -v](#) command.

The **!cppexpr** extension is useful for determining the type of a C++ exception.

[Send comments about this topic to Microsoft](#)

!cpuid

5/31/2017 • 1 min to read • [Edit Online](#)

The **!cpuid** extension displays information about the processors on the system.

```
!cpuid [Processor]
```

Parameters

Processor

Specifies the processor whose information will be displayed. If you omit this parameter, all processors are displayed.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about how to debug multiprocessor computers, see [Multiprocessor Syntax](#).

Remarks

The **!cpuid** extension works during live user-mode or kernel-mode debugging, local kernel debugging, and debugging of dump files. However, user-mode minidump files contain only information about the active processor.

If you are debugging in user mode, the **!cpuid** extension describes the computer that the target application is running on. In kernel mode, it describes the target computer.

The following example shows this extension.

```
kd> !cpuid
CP  F/M/S  Manufacturer      MHz
 0  6,5,1  GenuineIntel      700
 1  8,1,5  AuthenticAMD      700
```

The **CP** column gives the processor number. (These numbers are always sequential, starting with zero). The **Manufacturer** column specifies the processor manufacturer. The **MHz** column specifies the processor speed, if it is available.

For an x86-based processor or an x64-based processor, the **F** column displays the processor family number, the **M** column displays the processor model number, and the **S** column displays the stepping size.

For an Itanium-based processor, the **M** column displays the processor model number, the **R** column displays the processor revision number, the **F** column displays the processor family number, and the **A** column displays the architecture revision number.

[Send comments about this topic to Microsoft](#)

!cs

5/31/2017 • 3 min to read • [Edit Online](#)

The **!cs** extension displays one or more critical sections or the whole critical section tree.

```
!cs [-s] [-l] [-o]
!cs [-s] [-o] Address
!cs [-s] [-l] [-o] StartAddress EndAddress
!cs [-s] [-o] -d InfoAddress
!cs [-s] -t [TreeAddress]
!cs -?
```

Parameters

-s

Displays each critical section's initialization stack trace, if this information is available.

-l

Display only the locked critical sections.

-o

Displays the owner's stack for any locked critical section that is being displayed.

Address

Specifies the address of the critical section to display. If you omit this parameter, the debugger displays all critical sections in the current process.

StartAddress

Specifies the beginning of the address range to search for critical sections.

EndAddress

Specifies the end of the address range to search for critical sections.

-d

Displays critical sections that are associated with DebugInfo.

InfoAddress

Specifies the address of the DebugInfo.

-t

Displays a critical section tree. Before you can use the **-t** option, you must activate [Application Verifier](#) for the target process and select the **Check lock usage** option.

TreeAddress

Specifies the address of the root of the critical section tree. If you omit this parameter or specify zero, the debugger displays the critical section tree for the current process.

-?

Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Unavailable
--------------	-------------

Additional Information

For other commands and extensions that can display critical section information, see [Displaying a Critical Section](#). For more information about critical sections, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The **!cs** extension requires full symbols (including type information) for the process that is being debugged and for Ntdll.dll. If you do not have symbols for Ntdll.dll, see [Installing Windows Symbol Files](#).

The following examples shows you how to use **!cs**. The following command displays information about the critical section at address 0x7803B0F8 and shows its initialization stack trace.

```
0:001> !cs -s 0x7803B0F8
Critical section  = 0x7803B0F8 (MSVCRT!__app_type+0x4)
DebugInfo        = 0x6A262080
NOT LOCKED
LockSemaphore   = 0x0
SpinCount        = 0x0

Stack trace for DebugInfo = 0x6A262080:
0x6A2137BD: ntdll!RtlInitializeCriticalSectionAndSpinCount+0x9B
0x6A207A4C: ntdll!LdrpCallInitRoutine+0x14
0x6A205569: ntdll!LdrpRunInitializeRoutines+0x1D9
0x6A20DCE1: ntdll!LdrpInitializeProcess+0xAE5
```

The following command displays information about the critical section whose DebugInfo is at address 0x6A262080.

```
0:001> !cs -d 0x6A262080
DebugInfo        = 0x6A262080
Critical section  = 0x7803B0F8 (MSVCRT!__app_type+0x4)
NOT LOCKED
LockSemaphore   = 0x0
SpinCount        = 0x0
```

The following command displays information about all of the active critical sections in the current process.

```
## 0:001> !cs

DebugInfo      = 0x6A261D60
Critical section = 0x6A262820 (ntdll!RtlCriticalSectionLock+0x0)
LOCKED
LockCount      = 0x0
OwningThread   = 0x460

...

```

The following command displays the critical section tree.

```
0:001> !cs -t

Tree root 00bb08c0

Level      Node      CS      Debug  InitThr  EnterThr  WaitThr  TryEnThr  LeaveThr  EnterCnt  WaitCnt
##
```

Level	Node	CS	Debug	InitThr	EnterThr	WaitThr	TryEnThr	LeaveThr	EnterCnt	WaitCnt
0	00bb08c0 77c7e020 77fbcae0	4c8	4c8	0	0	4c8	c	0		
1	00dd6fd0 0148cfe8 01683fe0	4c8	4c8	0	0	4c8	2	0		
2	00bb0aa0 008e8b84 77fbcc20	4c8	0	0	0	0	0	0		
3	00bb09e0 008e8704 77fbcb0	4c8	0	0	0	0	0	0		
4	00bb0a40 008e8944 77fbcb0	4c8	0	0	0	0	0	0		
5	00bb0a10 008e8824 77fbcbc0	4c8	0	0	0	0	0	0		
5	00bb0a70 008e8a64 77fbcc00	4c8	0	0	0	0	0	0		
3	00bb0b00 008e8dc4 77fbcc60	4c8	0	0	0	0	0	0		
4	00bb0ad0 008e8ca4 77fbcc40	4c8	0	0	0	0	0	0		
4	00bb0b30 008e8ee4 77fbcc80	4c8	0	0	0	0	0	0		
5	00dd4fd0 0148afe4 0167ffe0	4c8	0	0	0	0	0	0		
2	00bb0e90 77c2da98 00908fe0	4c8	4c8	0	0	4c8	3a	0		
3	00bb0d70 77c2da08 008fcfe0	4c8	0	0	0	0	0	0		

The following items appear in this **!cs -t** display:

- **InitThr** is the thread ID for the thread that initialized the CS.
- **EnterThr** is the ID of the thread that called **EnterCriticalSection** last time.

- **WaitThr** is the ID of the thread that found the critical section that another thread owned and waited for it last time.
- **TryEnThr** is the ID of the thread that called **TryEnterCriticalSection** last time.
- **LeaveThr** is the ID of the thread that called **LeaveCriticalSection** last time
- **EnterCnt** is the count of **EnterCriticalSection**.
- **WaitCnt** is the contention count.

[Send comments about this topic to Microsoft](#)

!cxr

5/26/2017 • 1 min to read • [Edit Online](#)

The **!cxr** extension command is obsolete. Use the [.cxr \(Display Context Record\)](#) command instead.

[Send comments about this topic to Microsoft](#)

!dh

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dh** extension displays the headers for the specified image.

```
!dh [Options] Address
!dh -h
```

Parameters

Options

Any one of the following options:

-f

Displays file headers.

-s

Displays section headers.

-a

Displays all header information.

Address

Specifies the hexadecimal address of the image.

-h

Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Dbghelp.dll Kdextx86.dll Ntsdexts.dll
Windows XP and later	Dbghelp.dll

Remarks

The [!lmi](#) extension extracts the most important information from the image header and displays it in a concise summary format. That extension is frequently more useful than **!dh**.

[Send comments about this topic to Microsoft](#)

!dlls

5/31/2017 • 3 min to read • [Edit Online](#)

The **!dlls** extension displays the table entries of all loaded modules or all modules that a specified thread or process are using.

```
!dlls [Options] [LoaderEntryAddress]  
!dlls -h
```

Parameters

Options

Specifies the level of output. This parameter can be any combination of the following values:

-f

Displays file headers.

-s

Displays section headers.

-a

Displays complete module information. (This option is equivalent to **-f -s**.)

-c ** ModuleAddress**

Displays the module that contains *ModuleAddress*.

-i

Sorts the display by initialization order.

-l

Sorts the display by load order. This situation is the default.

-m

Sorts the display by memory order.

-v

(Windows XP and later) Displays version information. This information is taken from the resource section of each module.

LoaderEntryAddress

Specifies the address of the loader entry for a module. If you include this parameter, the debugger displays only this specific module.

-h

Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Kdextx86.dll Ntsdexts.dll
Windows XP and later	Exts.dll

Remarks

The module listing includes all entry points into each module.

The **.dlls** extension works only in live debugging (not with crash dump analysis).

In kernel mode, this extension displays the modules for the current [process context](#). You cannot use **!dlls** together with a system process or the idle process.

The following examples shows you how to use the **!dlls** extension.

```
kd> !dlls -c 77f60000

!dml_proc

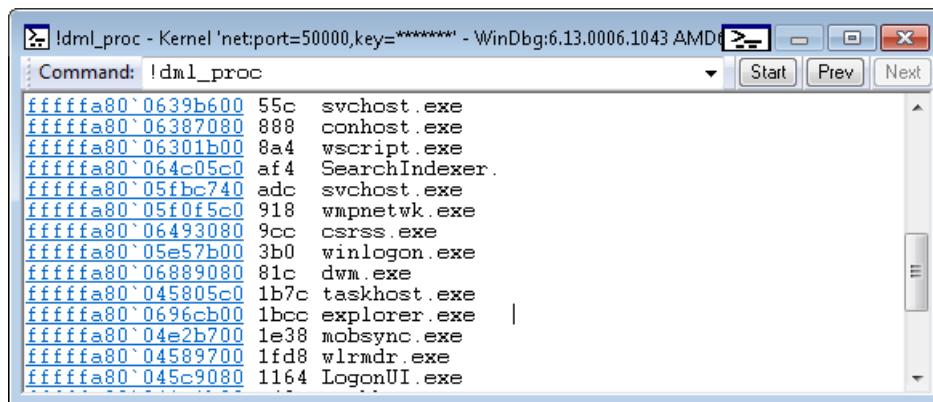

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dml_proc** extension displays a list of processes and provides links for obtaining more detailed information about processes.

```
!dml_proc
```

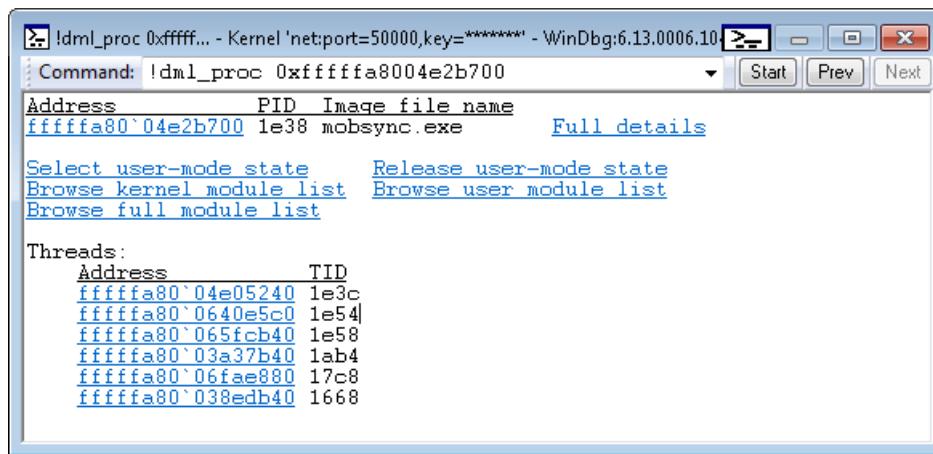

Remarks

The following image shows a portion of the output displayed by **!dml_proc**.

Address	PID	Image file name
fffffa80`0639b600	55c	svchost.exe
fffffa80`06387080	888	conhost.exe
fffffa80`06301b00	8a4	wscript.exe
fffffa80`064c05c0	af4	SearchIndexer.exe
fffffa80`05fbc740	adc	svchost.exe
fffffa80`05f0f5c0	918	wmpnetwk.exe
fffffa80`06493080	9cc	csrss.exe
fffffa80`05e57b00	3b0	winlogon.exe
fffffa80`06889080	81c	dwm.exe
fffffa80`045805c0	1b7c	taskhost.exe
fffffa80`0696cb00	1bcc	explorer.exe
fffffa80`04e2b700	1e38	mobsync.exe
fffffa80`04589700	1fd8	wlrmdr.exe
fffffa80`045c9080	1164	LogonUI.exe

In the preceding output, the process addresses are links that you can click to see more detailed information. For example, if you click **fffffa80`04e2b700** (the address for mobsync.exe), you will see detailed information about the mobsync.exe process as shown in the following image.

Address	PID	Image file name
fffffa80`04e2b700	1e38	mobsync.exe

Address: fffffa80`04e2b700 PID: 1e38 Image file name: mobsync.exe

[Full details](#)

!dumpfa

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dumpfa** extension displays the contents of a failure analysis entry.

```
!dumpfa Address
```

Parameters

Address

Specifies the address of the failure analysis entry that is displayed.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

The **.dumpfa** extension is useful only to debug the **!analyze** extension, as the following example shows.

```
0:000> !dumpfa 0x00a34140
DataUsed 3b0
Type = DEBUG_FLR_MARKER_BUCKET 00010016 - Size = 9
Type = DEBUG_FLR_MARKER_FILE 0001000d - Size = 16
Type = DEBUG_FLR_SYSXML_LOCALEID 00004200 - Size = 4
Type = DEBUG_FLR_SYSXML_CHECKSUM 00004201 - Size = 4
Type = DEBUG_FLR_READ_ADDRESS 0000000e - Size = 8
Type = DEBUG_FLRFAULTING_IP 80000000 - Size = 8
Type = DEBUG_FLR_MM_INTERNAL_CODE 00001004 - Size = 8
Type = DEBUG_FLR_CPU_MICROCODE_VERSION 0000301f - Size = 28
Type = DEBUG_FLR_CUSTOMER_CRASH_COUNT 0000300b - Size = 8
Type = DEBUG_FLR_DEFAULT_BUCKET_ID 00010008 - Size = 12
Type = DEBUG_FLR_BUGCHECK_STR 00000600 - Size = 5
Type = DEBUG_FLR_LAST_CONTROL_TRANSFER 0000000a - Size = 18
Type = DEBUG_FLR_TRAP_FRAME c0000002 - Size = 8
Type = DEBUG_FLR_STACK_TEXT 00010005 - Size = 1fb
Type = DEBUG_FLR_STACK_COMMAND 00010004 - Size = 17
Type = DEBUG_FLR_OS_BUILD_NAME 0000301e - Size = 9
Type = DEBUG_FLR_MODULE_NAME 00010006 - Size = 8
Type = DEBUG_FLR_IMAGE_NAME 00010001 - Size = c
Type = DEBUG_FLR_IMAGE_TIMESTAMP 80000002 - Size = 8
```

You can also use the **!asd** extension to debug the **!analyze** extension.

[Send comments about this topic to Microsoft](#)

!elog_str

5/31/2017 • 1 min to read • [Edit Online](#)

The **!elog_str** extension adds a string to the event log.

```
!elog_str String
```

Parameters

String

Specifies the string to add to the event log.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

Because a registered event source does not send *String*, the string appears in the event log with a warning that no event ID was determined.

[Send comments about this topic to Microsoft](#)

!envvar

5/31/2017 • 1 min to read • [Edit Online](#)

The **!envvar** extension displays the value of the specified environment variable.

```
!envvar Variable
```

Parameters

Variable

Specifies the environment variable whose value is displayed. *Variable* is not case sensitive.

DLL

Windows 2000	Unavailable
Windows XP and later	Exts.dll

Additional Information

For more information about environment variables, see [Environment Variables](#) and the Microsoft Windows SDK documentation.

Remarks

The **!envvar** extension works both in user mode and in kernel mode. However, in kernel mode, when you set the idle thread as the current process, the pointer to the Process Environment Block (PEB) is **NULL**, so it fails. In kernel mode, the **!envvar** extension displays the environment variables on the target computer, as the following example shows.

```
0:000> !envvar _nt_symbol_path
_nt_symbol_path = srv*C:\mysyms*https://msdl.microsoft.com/download/symbols
```

[Send comments about this topic to Microsoft](#)

!error

5/31/2017 • 1 min to read • [Edit Online](#)

The **!error** extension decodes and displays information about an error value.

```
!error Value [Flags]
```

Parameters

Value

Specifies one of the following error codes:

- Win32
- Winsock
- NTSTATUS
- NetAPI

Flags

If *Flags* is set to 1, the error code is read as an NTSTATUS code.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

The following example shows you how to use **!error**.

```
0:000> !error 2
Error code: (Win32) 0x2 (2) - The system cannot find the file specified.
0:000> !error 2 1
Error code: (NTSTATUS) 0x2 - STATUS_WAIT_2
```

[Send comments about this topic to Microsoft](#)

!exchain

5/31/2017 • 1 min to read • [Edit Online](#)

The **!exchain** extension displays the current exception handler chain.

```
!exchain [Options]
```

Parameters

Options

One of the following values:

/c

Displays information that is relevant for debugging a C++ **try/catch** exception, if such an exception is detected.

/C

Displays information that is relevant for debugging a C++ **try/catch** exception, even when such an exception has not been detected.

/f

Displays information that is obtained by walking the CRT function tables, even if a CRT exception handler was not detected.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

The **!exchain** extension is available only for an x86-based target computer.

Remarks

The **!exchain** extension displays the list of exception handlers for the current thread.

The list begins with the first handler on the chain (the one that is given the first opportunity to handle an exception) and continues on to the end. The following example shows this extension.

```
0:000> !exchain
0012fea8: Prymes!_except_handler3+0 (00407604)
    CRT scope 0, filter: Prymes!dzExcepError+e6 (00401576)
        func:  Prymes!dzExcepError+ec (0040157c)
0012ffb0: Prymes!_except_handler3+0 (00407604)
    CRT scope 0, filter: Prymes!mainCRTStartup+f8 (004021b8)
        func:  Prymes!mainCRTStartup+113 (004021d3)
0012ffe0: KERNEL32!GetThreadContext+1c (77ea1856)
```

[Send comments about this topic to Microsoft](#)

!exr

5/26/2017 • 1 min to read • [Edit Online](#)

The **!exr** extension command is obsolete. Use the [.exr \(Display Exception Record\)](#) command instead.

[Send comments about this topic to Microsoft](#)

!findxmldata

5/31/2017 • 1 min to read • [Edit Online](#)

The **!findxmldata** extension retrieves XML data from a CAB file that contains a kernel-mode Small Memory Dump file.

```
!findxmldata [ -d DeviceName | -h HwId ]
!findxmldata -r Driver
!findxmldata -checksum [ -z CabFile ]
!findxmldata -v
```

Parameters

-d *DeviceName*

Displays all devices whose device name contains the string that *DeviceName* specifies.

-h *HwId*

Displays all devices whose hardware IDs contain the string that *HwId* specifies. If you use both **-d** and **-h**, the debugger displays only those devices that satisfy both matches.

-r *Driver*

Displays information about the driver that the *Driver* parameter specifies, including all devices that use this driver.

-checksum

Displays the XML file's checksum.

-z *CabFile*

Enables you to perform a checksum on the CAB file that the *CabFile* parameter specifies, instead of on the default Sysdata.xml file.

-v

Displays system version information.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

The **!findxmldata** extension works only on a kernel-mode Small Memory Dump file that is stored in a CAB file.

Additional Information

For more information about how to put dump files into CAB files, see [.dumpcab \(Create Dump File CAB\)](#). For information more about how to debug a kernel-mode dump file, including dump files that are stored inside CAB files, see [Analyzing a Kernel-Mode Dump File](#).

Remarks

The **!findxmldata** extension retrieves data from the Sysdata.xml file that is stored in a CAB file that contains a kernel-mode [Small Memory Dump](#) file.

When you do not use any options, the extension displays all devices.

The following examples show you how to use **!findxmldata**.

```
kd> !findxmldata -v

[Send comments about this topic to Microsoft](#)

!for_each_frame

5/31/2017 • 1 min to read • [Edit Online](#)

The **!for_each_frame** extension executes a debugger command one time for each frame in the stack of the current thread.

```
!for_each_frame ["CommandString"]
!for_each_frame -?
```

Parameters

CommandString

Specifies the debugger commands to execute one time for each frame. If *CommandString* includes multiple commands, you must separate them with semicolons and enclose *CommandString* in quotation marks. If you include multiple commands, the individual commands within *CommandString* cannot contain quotation marks. If you want to refer to the index of the current frame within *CommandString*, use the @\$frame pseudoregister.

-?

Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about the local context, see [Changing Contexts](#).

Remarks

If you do not specify any arguments, the **!for_each_frame** extension displays a list of all frames and their frame indexes. For a more detailed list of all frames, use the [k \(Display Stack Backtrace\)](#) command.

The [k](#) command walks up to 256 frames. For each enumerated frame, that frame temporarily becomes the current local context (similar to the [.frame \(Set Local Context\)](#) command). After the context has been set, *CommandString* is executed. After all frames have been used, the local context is reset to the value that it had before you used the **!for_each_frame** extension.

If you include *CommandString*, the debugger displays the frame and its index before the command is executed for that frame.

The following command displays all local variables for the current stack.

```
!for_each_frame !for_each_local dt #@Local
```

[Send comments about this topic to Microsoft](#)

!for_each_function

5/31/2017 • 1 min to read • [Edit Online](#)

The **!for_each_function** extension executes a debugger command for each function, in a specified module, whose name matches a specified pattern.

```
!for_each_function -m:ModuleName -p:Pattern -c:CommandString
!for_each_function -?
```

Parameters

-m:ModuleName

Specifies the module name. This name is typically the file name without the file name extension. In some cases, the module name differs significantly from the file name.

-p:Pattern

Specifies the pattern to be matched.

-c:CommandString

Specifies the debugger command to execute for each function, in the specified module, that matches the pattern.

You can use the following aliases in *CommandString*.

ALIAS	DATA TYPE	VALUE
@#SymbolName	string	The symbol name.
@#SymbolAddress	ULONG64	The symbol address.
@#ModName	string	The module name.
@#FunctionName	string	The function name.

-?

Displays help for this extension.

DLL

Ext.dll

Remarks

The following example shows how to list all function names, in the PCI module, that match the pattern *read*.

```
1: kd> !for_each_function -m:pci -p:*read* -c:.echo @#FunctionName

PciReadDeviceConfig
PciReadDeviceSpace

PpRegStateReadCreateClassCreationSettings
ExpressRootPortReadConfigSpace
PciReadRomImage
PciDevice_ReadConfig
PciReadDeviceConfigEx
PciReadSlotConfig
```

If an alias is not preceded and followed by a blank space, you must put the alias inside the [\\${} Alias Interpreter](#) token.

The following example shows how to list all symbols, in all modules, whose function names match the pattern *CreateFile*. The alias @#ModuleName is not preceded by a blank space. Therefore, it is put inside the [\\${} Alias Interpreter](#) token.

Note Do not confuse the @#ModuleName alias with the @#ModName alias. The @#ModuleName alias belongs to the [!for_each_module](#) extension, and the @#ModName alias belongs to the [!for_each_function](#) extension.

```
1: kd> !for_each_module !for_each_function -m:${@#ModuleName} -p:*CreateFile* -c:.echo @#SymbolName
nt!BiCreateFileDeviceElement
nt!NtCreateFile
...
Wdf01000!FxFileObject::_CreateFileObject
fltmgr!FltCreateFileEx2$fin$0
fltmgr!FltCreateFileEx2
...
Ntfs!TxfIoCreateFile
Ntfs!NtfsCreateFileLock
...
MpFilter!MpTxfpCreateFileEntryUnsafe
mrxsmb10!MRxSmbFinishLongNameCreateFile
...
srv!SrvIoCreateFile
```

You can put a sequence of commands in a command file, and use [\\$\\$>< \(Run Script File\)](#) to execute those commands for each function that matches the pattern. Suppose that a file named Commands.txt contains the following commands:

```
.echo
.echo @#FunctionName
u @#SymbolAddress L1
```

In the following example, the commands in the Commands.txt file are executed for each function, in the PCI module, that matches the pattern *read*.

```
1: kd> !for_each_function -m:pci -p:*read* -c:$><Commands.txt

PciReadDeviceConfig
pci!PciReadDeviceConfig [d:\wmm1\drivers\busdrv\pci\config.c @ 349]:
fffff880`00f7b798 48895c2408      mov     qword ptr [rsp+8],rbx

PciReadDeviceSpace
pci!PciReadDeviceSpace [d:\wmm1\drivers\busdrv\pci\config.c @ 1621]:
fffff880`00f7c044 48895c2408      mov     qword ptr [rsp+8],rbx

...
```

!for_each_local

5/31/2017 • 1 min to read • [Edit Online](#)

The **!for_each_local** extension executes a debugger command one time for each local variable in the current frame.

```
!for_each_local ["CommandString"]
!for_each_local -?
```

Parameters

CommandString

Specifies the debugger commands to execute one time for each local variable in the current stack frame. If *CommandString* includes multiple commands, you must separate them with semicolons and enclose *CommandString* in quotation marks. If you include multiple commands, the individual commands in *CommandString* cannot contain quotation marks.

Within *CommandString*, or within any script that the commands in *CommandString* execute, you can use the **@#Local** alias. This alias is replaced by the name of the local variable. This replacement occurs before *CommandString* is executed and before any other parsing occurs. This alias is case sensitive, and you must add a space before it and add a space after it, even if you enclose the alias in parentheses. If you use C++ expression syntax, you must reference this alias as **@@(@#Local)**.

This alias is available only during the lifetime of the call to **!for_each_local**. Do not confuse this alias with pseudo-registers, fixed-name aliases, or user-named aliases.

-?

Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about how to display and change local variables and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

If you do not specify any arguments, the **!for_each_local** extension lists local variables. For more information about the local variables, use the [dv \(Display Local Variables\)](#) command.

If you enable verbose debugger output, the display includes the total number of local variables when the extension is called, and every time that *CommandString* is executed for a local variable, that variable and the text of *CommandString* are echoed.

[Send comments about this topic to Microsoft](#)

!for_each_module

5/31/2017 • 4 min to read • [Edit Online](#)

The **!for_each_module** extension executes a debugger command one time for each loaded module.

```
!for_each_module ["CommandString"]
!for_each_module -?
```

Parameters

CommandString

Specifies the debugger commands to execute one time for each module in the debugger's module list. If *CommandString* includes multiple commands, you must separate them with semicolons and enclose *CommandString* in quotation marks. If you include multiple commands, the individual commands within *CommandString* cannot contain quotation marks.

You can use the following aliases in *CommandString* or in any script that the commands in *CommandString* executes.

ALIAS	DATA TYPE	VALUE
@#FileVersion	string	The file version of the module.
@#ProductVersion	string	The product version of the module.
@#ModuleIndex	ULONG	The module number. Modules are enumerated consecutively, starting with zero.
@#ModuleName	string	The module name. This name is typically the file name without the file name extension. In some situations, the module name differs significantly from the file name.
@#ImageName	string	The name of the executable file, including the file name extension. Typically, the full path is included in user mode but not in kernel mode.
@#LoadedImageName	string	Unless Microsoft CodeView symbols are present, this alias is the same as the image name.

ALIAS	DATA TYPE	VALUE
@#MappedImageName	string	In most situations, this alias is NULL . If the debugger is mapping an image file (for example, during minidump debugging), this alias is the name of the mapped image.
@#SymbolFileName	string	The path and name of the symbol file. If you have not loaded any symbols, this alias is the name of the executable file instead.
@#ModuleNameSize	ULONG	The string length of the module name string, plus one.
@#ImageNameSize	ULONG	The string length of the image name string, plus one.
@#LoadedImageNameSize	ULONG	The string length of the loaded image name string, plus one.
@#MappedImageNameSize	ULONG	The string length of the mapped image name string, plus one.
@#SymbolFileNameSize	ULONG	The string length of the symbol file name string, plus one.
@#Base	ULONG64	The address of the start of the image.
@#Size	ULONG	The size of the image, in bytes.
@#End	ULONG64	The address of the end of the image.
@#TimeStamp	ULONG	The time and date stamp of the image. If you want to expand this time and date stamp into a readable date, use the .formats (Show Number Formats) command.
@#Checksum	ULONG	The checksum of the module.

ALIAS	DATA TYPE	VALUE
@#Flags	ULONG	The module flags. For a list of the DEBUG_MODULE_Xxx values, see Dbgeng.h.
@#SymbolType	USHORT	The symbol type. For a list of the DEBUG_SYMTYPE_Xxx values, see Dbgeng.h.

These aliases are all replaced before *CommandString* is executed for each module and before any other parsing occurs. These aliases are case sensitive. You must add a space before the alias and a space after it, even if the alias is enclosed in parentheses. If you use C++ expression syntax, you must reference these aliases as @@(@#alias).

These aliases are available only during the lifetime of the call to **!for_each_module**. Do not confuse them with pseudo-registers, fixed-name aliases, or user-named aliases.

-?

Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about how to define and use aliases as shortcuts for entering character strings (including use of the \${ } token), see [Using Aliases](#).

Remarks

If you do not specify any arguments, the **!for_each_module** extension displays general information about the loaded modules. This information is similar to the information that the following command shows.

```
!for_each_module .echo #@ModuleIndex : #@Base #@End #@ModuleName #@ImageName #@LoadedImageName
```

For more information about loaded and unloaded modules, use the [!Im \(List Loaded Modules\)](#) command.

If you enable verbose debugger output, the debugger displays the total number of loaded and unloaded modules when the extension is called, and the debugger displays detailed information about each module (including the values of each available alias) before *CommandString* is executed for that module.

The following examples show how to use the **!for_each_module** extension. The following commands display the global debug flags.

```
!for_each_module x ${@#ModuleName}*!*Debug*Flag*
!for_each_module x ${@#ModuleName}*!g*Debug*
```

The following command checks for binary corruption in every loaded module, by using the [!chkimg](#) extension:

```
!for_each_module !chkimg @#ModuleName
```

The following command searches for the pattern "MZ" in every loaded image.

```
!for_each_module s-a @#Base @#End "MZ"
```

The following example demonstrates the use of @#FileVersion and @#ProductVersion for each module name:

```
0:000> !for_each_module .echo @#ModuleName fver = @#FileVersion pver = @#ProductVersion
USER32 fver = 6.0.6000.16438 (vista_gdr.070214-1610) pver = 6.0.6000.16438
kernel32 fver = 6.0.6000.16386 (vista_rtm.061101-2205) pver = 6.0.6000.16386

ole32 fver = 6.0.6000.16386 (vista_rtm.061101-2205) pver = 6.0.6000.16386
ADVAPI32 fver = 6.0.6000.16386 (vista_rtm.061101-2205) pver = 6.0.6000.16386
COMDLG32 fver = 6.0.6000.16386 (vista_rtm.061101-2205) pver = 6.0.6000.16386
```

[Send comments about this topic to Microsoft](#)

!for_each_register

5/31/2017 • 1 min to read • [Edit Online](#)

The **!for_each_register** extension executes a specified command for each register.

```
!for_each_register -c:CommandString
!for_each_register -?
```

Parameters

-c:CommandString

Specifies the command to be executed for each register. The aliases `@#RegisterName` and `@#RegisterValue` are valid during the execution of the command.

-?

Displays help for the **!for_each_register** extension.

DLL

Ext.dll

Examples

This example lists the name of each register.

```
0:000> !for_each_register -c:.echo @#RegisterName
rax
rcx
rdx
rbx
...
```

This example executes **!address** for each register value.

```
0:000> !for_each_register -c:!address ${@#RegisterValue}
...
Usage:           Stack
Base Address:   00000008`a568f000
End Address:   00000008`a56a0000
Region Size:   00000000`00011000
State:          00001000  MEM_COMMIT
Protect:        00000004  PAGE_READWRITE
Type:           00020000  MEM_PRIVATE
Allocation Base: 00000008`a5620000
Allocation Protect: 00000004  PAGE_READWRITE
More info:      ~0k
...
```

Remarks

When an alias is an argument to a debugger extension (for example, **!address**), use the alias interpreter **{} (Alias Interpreter)** token so that the alias is resolved correctly.

For more information about how to define and use aliases as shortcuts for entering character strings (including use of the `$()` token), see [Using Aliases](#).

[Send comments about this topic to Microsoft](#)

!gflag

5/31/2017 • 2 min to read • [Edit Online](#)

The **!gflag** extension sets or displays the global flags.

```
!gflag [+|-] Value
!gflag {+|-} Abbreviation
!gflag -?
!gflag
```

Parameters

Value

Specifies a 32-bit hexadecimal number. If you do not use a plus sign (+) or minus sign (-), this number becomes the new value of the global flag bit field. If you add a plus sign (+) before this number, the number specifies one or more global flag bits to set to 1. If you add a minus sign (-) before this number, the number specifies one or more global flag bits to set to zero.

Abbreviation

Specifies a single global flag. *Abbreviation* is a three-letter abbreviation for a global flag that is set to 1 (+) or to zero (-).

-?

Displays some Help text for this extension, including a list of global flag abbreviations, in the [Debugger Command window](#).

DLL

Windows 2000	Kdextx86.dll Ntsdexts.dll
Windows XP and later	Exts.dll

Additional Information

You can also set these flags by using the Global Flags utility (Gflags.exe).

Remarks

If you do not specify any arguments, the **!gflag** extension displays the current global flag settings.

The following table contains the abbreviations that you can use for the *Abbreviation* parameter.

VALUE	NAME	DESCRIPTION
0x00000001	"soe"	Stop on exception.
0x00000002	"sls"	Show loader snaps.

VALUE	NAME	DESCRIPTION
0x00000004	"dic"	Debug initial command.
0x00000008	"shg"	Stop if the GUI stops responding (that is, hangs).
0x00000010	"htc"	Enable heap tail checking.
0x00000020	"hfc"	Enable heap free checking.
0x00000040	"hpc"	Enable heap parameter checking.
0x00000080	"hvc"	Enable heap validation on call.
0x00000100	"ptc"	Enable pool tail checking.
0x00000200	"pfc"	Enable pool free checking.
0x00000400	"ptg"	Enable pool tagging.
0x00000800	"htg"	Enable heap tagging.
0x00001000	"ust"	Create a user-mode stack trace DB.
0x00002000	"kst"	Create a kernel-mode stack trace DB.
0x00004000	"otl"	Maintain a list of objects for each type.
0x00008000	"htd"	Enable heap tagging by DLL.
0x00010000	"idp"	Unused.
0x00020000	"d32"	Enable debugging of the Microsoft Win32 subsystem.
0x00040000	"ksl"	Enable loading of kernel debugger symbols.

VALUE	NAME	DESCRIPTION
0x00080000	"dps"	Disable paging of kernel stacks.
0x00100000	"scb"	Enable critical system breaks.
0x00200000	"dhc"	Disable heap coalesce on free.
0x00400000	"ece"	Enable close exception.
0x00800000	"eel"	Enable exception logging.
0x01000000	"eot"	Enable object handle type tagging.
0x02000000	"hpa"	Put heap allocations at the end of pages.
0x04000000	"dwI"	Debug WINLOGON.
0x08000000	"ddp"	Disable kernel-mode DbgPrint and KdPrint output.
0x10000000	NULL	Unused.
0x20000000	"sue"	Stop on unhandled user-mode exception
0x40000000	NULL	Unused.
0x80000000	"dpd"	Disable protected DLL verification.

[Send comments about this topic to Microsoft](#)

!gle

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gle** extension displays the last error value for the current thread.

```
!gle [-all]
```

Parameters

-all

Displays the last error for each user-mode thread on the target system. If you omit this parameter in user mode, the debugger displays the last error for the current thread. If you omit this parameter in kernel mode, the debugger displays the last error for the thread that the current [register context](#) specifies.

DLL

Windows 2000	Ext.dll Ntsdexts.dll
Windows XP and later	Ext.dll

Additional Information

For more information about the [GetLastError](#) routine, see the Microsoft Windows SDK documentation.

Remarks

The **!gle** extension displays the value of [GetLastError](#) and tries to decode this value.

In kernel mode, the **!gle** extension work only if the debugger can read the thread environment block (TEB).

[Send comments about this topic to Microsoft](#)

!gs

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gs** extension analyzes a /GS stack overflow.

```
!gs
```

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

The **!gs** extension helps debug buffer overruns. Run **!gs** when you encounter a STATUS_STACK_BUFFER_OVERRUN error, as the following example shows.

```
0:000> !gs
Corruption occurred in mshtml!CDoc::OnPaint or one of its callers
Real canary not found at 0x74866010
Canary at gsfailure frame 0x292ea4e7
Corrupted canary 0x0013e2c8: 0x00000000
Corrupted cookie value too generic, skipping init bit-flip check
a caller of mshtml!CDoc::OnPaint has corrupted the EBP from 0x0013e254 to 0x0013
e234
check callers (without canary) of mshtml!CDoc::OnPaint for 0x1 bytes of overflow

The canary doesn't look corrupted. Not sure how we got here

!handle

5/31/2017 • 4 min to read • [Edit Online](#)

The **!handle** extension displays information about a handle or handles that one or all processes in the target system own.

User-Mode

```
!handle [Handle [UMFlags [TypeName]]]
!handle -?
```

Kernel-Mode

```
!handle [Handle [KMFlags [Process [TypeName]]]]
```

Parameters

Handle

Specifies the index of the handle to display. If *Handle* is -1 or if you omit this parameter, the debugger displays data for all handles that are associated with the current process. If *Handle* is 0, the debugger displays data for all handles.

UMFlags

(User mode only) Specifies what the display should contain. This parameter can be a sum of any of the following bit values. (The default value is 0x1.)

Bit 0 (0x1)

Displays handle type information.

Bit 1 (0x2)

Displays basic handle information.

Bit 2 (0x4)

Displays handle name information.

Bit 3 (0x8)

Displays object-specific handle information, when available.

KMFlags

(Kernel mode only) Specifies what the display should contain. This parameter can be a sum of any of the following bit values. (The default value is 0x3.)

Bit 0 (0x1)

Displays basic handle information.

Bit 1 (0x2)

Displays information about objects.

Bit 2 (0x4)

Displays free handle entries. If you do not set this bit and you omit *Handle* or set it to zero, the list of handles that are displayed does not include free handles. If *Handle* specifies a single free handle, it is displayed even if you do not set this bit.

Bit 4 (0x10)

(Windows XP and later) Displays the handle from the kernel handle table instead of the current process.

Bit 5 (0x20)

(Windows XP and later) Interprets the handle as a thread ID or process ID and displays information about the corresponding kernel object.

Process

(Kernel mode only) Specifies a process. You can use the process ID or the hexadecimal address of the process object. This parameter must refer to a currently running process on the target system. If this parameter is -1 or if you omit it, the current process is used. If this parameter is 0, handle information from all processes is displayed.

TypeName

Specifies the type of handle that you want to examine. Only handles that match this type are displayed. *TypeName* is case sensitive. Valid types include Event, Section, File, Port, Directory, SymbolicLink, Mutant, WindowStation, Semaphore, Key, Token, Process, Thread, Desktop, IoCompletion, Timer, Job, and WaitablePort.

-?

(User mode only) Displays some Help text for this extension in the [Debugger Command window](#).

DLL

Windows 2000	Kdextx86.dll Uext.dll Ntsdexts.dll
Windows XP and later	Kdexts.dll Uext.dll Ntsdexts.dll

Additional Information

For more information about handles, see the [!htrace](#) extension, the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

You can use the **!handle** extension during user-mode and kernel-mode live debugging. You can also use this extension on kernel-mode dump files. However, you cannot use this extension on user-mode dump files, unless you specifically created them with handle information. (You can create such dump files by using the [.dump /mh \(Create Dump File\)](#) command.)

During live user-mode debugging, you can use the [.closehandle \(Close Handle\)](#) command to close one or more handles.

The following examples are user-mode examples of the **!handle** extension. The following command displays a list of all handles.

```
0:000> !handle
Handle 4
  Type      Section
Handle 8
  Type      Event
Handle c
  Type      Event
Handle 10
  Type      Event
Handle 14
  Type      Directory
Handle 5c
  Type      File
6 Handles
Type      Count
Event     3
Section   1
File      1
Directory 1
```

The following command displays detailed information about handle 0x8.

```
0:000> !handle 8 f
Handle 8
  Type      Event
  Attributes 0
  GrantedAccess 0x100003:
    Synch
    QueryState,ModifyState
  HandleCount 2
  PointerCount 3
  Name      <none>
  Object Specific Information
    Event Type Auto Reset
    Event is Waiting
```

The following examples are kernel-mode examples of **!handle**. The following command lists all handles, including free handles.

```
kd> !handle 0 4
processor number 0

!heap

5/31/2017 • 15 min to read • [Edit Online](#)

The **!heap** extension displays heap usage information, controls breakpoints in the heap manager, detects leaked heap blocks, searches for heap blocks, or displays page heap information.

This extension supports the segment heap and the NT heap. Use **!heap** with no parameter to list all heaps and their type.

```
!heap [HeapOptions] [ValidationOptions] [Heap]
!heap -b [{alloc|realloc|free} [Tag]] [Heap | BreakAddress]
!heap -B {alloc|realloc|free} [Heap | BreakAddress]
!heap -l
!heap -s [SummaryOptions] [StatHeapAddress]
!heap -i HeapAddress
!heap -x [-v] Address
!heap -p [PageHeapOptions]
!heap -srch [Size] Pattern
!heap -flt FilterOptions
!heap -stat [-h Handle [-grp GroupBy [MaxDisplay]]]
!heap [-p] -?
!heap -triage [Handle | Address]
```

Segment and NT Heap Parameters

These parameters work with Segment and NT heaps.

-s

Specifies that summary information is being requested. If *SummaryOptions* and *StatHeapAddress* are omitted, then summary information is displayed for all heaps associated with the current process.

SummaryOptions

Can be any combination of the following options. The *SummaryOptions* are not case-sensitive. Type **!heap -s -?** for additional information.

OPTION	EFFECT
-v	Verifies all data blocks.
-b <i>BucketSize</i>	Specifies the bucket size. The default is 1024 bits.
-d <i>DumpBlockSize</i>	Specifies the bucket size.
-a	Dumps all heap blocks.
-c	Specifies that the contents of each block should be displayed.

-triage [*Handle* | *Address*]

Causes the debugger to automatically search for failures in a process's heaps. If a heap handle is specified as an argument, that heap is examined; otherwise, all the heaps are searched for one that contains the given address, and if one is found, it is examined. Using **-triage** is the only way to validate low-fragmentation heap (LFH) corruption.

-x ** [-v]**

Causes the debugger to search for the heap block containing the specified address. If **-v** is added, the command will search the entire virtual memory space of the current process for pointers to this heap block.

-l

Causes the debugger to detect leaked heap blocks.

-i ** Address -h HeapAddress**

Displays information about the specified *Heap*.

Address

Specifies the address to search for.

-?

Displays some brief Help text for this extension in the Debugger Command window. Use **!heap -?** for generic help, and **!heap -p -?** for page heap help.

NT Heap Parameters

These parameters work only with the NT Heap.

HeapOptions

Can be any combination of the following options. The *HeapOptions* values are case-sensitive.

OPTION	EFFECT
-v	Causes the debugger to validate the specified heap. <div style="border: 1px solid black; padding: 5px;">Note This option does not detect low fragmentation heap (LFH) corruption. Use -triage instead.</div>
-a	Causes the display to include all information for the specified heap. Size, in this case, is rounded up to the heap granularity. (Running !heap with the -a option is equivalent to running it with the three options -h -f -m , which can take a long time.)
-h	Causes the display to include all non-LFH entries for the specified heap.
-hl	Causes the display to include all the entries for the specified heap(s), including LFH entries.
-f	Causes the display to include all the free list entries for the specified heap.

OPTION	EFFECT
-m	Causes the display to include all the segment entries for the specified heap.
-t	Causes the display to include the tag information for the specified heap.
-T	Causes the display to include the pseudo-tag entries for the specified heap.
-g	Causes the display to include the global tag information. Global tags are associated with each untagged allocation.
-s	Causes the display to include summary information for the specified heap.
-k	(x86-based targets only) Causes the display to include the stack backtrace associated with each entry.

ValidationOptions

Can be any single one of the following options. The *ValidationOptions* are case-sensitive.

OPTION	EFFECT
-D	Disables validate-on-call for the specified heap.
-E	Enables validate-on-call for the specified heap.
-d	Disables heap checking for the specified heap.
-e	Enables heap checking for the specified heap.

-i ** Heap **** Address or HeapAddress**

Displays information about the specified *Heap*.

BreakAddress

Specifies the address of a block where a breakpoint is to be set or removed.

-b

Causes the debugger to create a conditional breakpoint in the heap manager. The **-b** option can be followed by **alloc**, **realloc**, or **free**; this specifies whether the breakpoint will be activated by allocating, reallocating, or freeing memory. If *BreakAddress* is used to specify the address of the block, the breakpoint type can be omitted. If *Heap* is used to specify the heap address or heap index, the type must be included, as well as the *Tag* parameter.

Tag

Specifies the tag name within the heap.

-B

Causes the debugger to remove a conditional breakpoint from the heap manager. The breakpoint type (**alloc**, **realloc**, or **free**) must be specified, and must be the same as that used with the **-b** option.

StatHeapAddress

Specifies the address of the heap. If this is 0 or omitted, all heaps associated with the current process are displayed.

-p

Specifies that page heap information is being requested. If this is used without any *PageHeapOptions*, all page heaps will be displayed.

PageHeapOptions

Can be any single one of the following options. The *PageHeapOptions* are case-sensitive. If no options are specified, then all possible page heap handles will be displayed.

OPTION	EFFECT
-h Handle	Causes the debugger to display detailed information about a page heap with handle <i>Handle</i> .
-a Address	Causes the debugger to find the page heap whose block contains <i>Address</i> . Full details of how this address relates to full-page heap blocks will be included, such as whether this address is part of a page heap, its offset inside the block, and whether the block is allocated or was freed. Stack traces are included whenever available. When using this option, size is displayed in multiples of the heap allocation granularity.
-t[c s] [Traces]	Causes the debugger to display the collected traces of the heavy heap users. <i>Traces</i> specifies the number of traces to display; the default is four. If there are more traces than the specified number, the earliest traces are displayed. If -t or -tc is used, the traces are sorted by count usage. If -ts is used, the traces are sorted by size. (The -tc and -ts options are supported in Windows XP only; the -t option is supported only in Windows XP and earlier versions of Windows.)
-fi [Traces]	Causes the debugger to display the most recent fault injection traces. <i>Traces</i> specifies the quantity to be displayed; the default is 4.
-all	Causes the debugger to display detailed information about all page heaps.
-?	Causes the debugger to display page heap help, including a diagram of heap blocks. (These diagrams can also be seen in the following Remarks section.)

Before you can use any **!heap -p** extension command, the page heap must be enabled for your target process. See details in the following Remarks section.

-srch

Scans all heaps for the given pattern.

Pattern

Specifies a pattern for which to look.

Size

Can be any single one of the following options. This specifies the size of the pattern. The '-' is required.

OPTION	EFFECT
-b	The pattern is one BYTE in size.
-w	The pattern is one WORD in size.
-d	The pattern is one DWORD in size.
-q	The pattern is one QWORD in size.

If none of the above are specified, then the pattern is assumed to be of the same size as the machine pointer.

-flt

Limits the display to include only heaps with the specified size or size range.

FilterOptions

Can be any single one of the following options. The *FilterOptions* are case-sensitive.

OPTION	EFFECT
s Size	Limits the display to include only heaps of the specified size.
r SizeMin SizeMax	Limits the display to include only heaps within the specified size range.

-stat

Displays usage statistics for the specified heap.

-h Handle

Causes usage statistics for only the heap at *Handle* to be displayed. If *Handle* is 0 or omitted, then usage statistics for all heaps are displayed.

-grp ** GroupBy**

Reorders the display as specified by *GroupBy*. The options for *GroupBy* can be found in the following table.

OPTION	EFFECT
A	Displays the usage statistics according to allocation size.
B	Displays the usage statistics according to block count.

OPTION	EFFECT
S	Displays the usage statistics according to the total size of each allocation.

MaxDisplay

Limits the output to only *MaxDisplay* number of lines.

DLL

Windows XP and later	Ext.dll Exts.dll
-----------------------------	------------------

Additional Information

For information about heaps, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

This extension command can be used to perform a variety of tasks.

The standard **!heap** command is used to display heap information for the current process. (This should be used only for user-mode processes. The **!pool** extension command should be used for system processes.)

The **!heap -b** and **!heap -B** commands are used to create and delete conditional breakpoints in the heap manager.

The **!heap -l** command detects leaked heap blocks. It uses a garbage collector algorithm to detect all busy blocks from the heaps that are not referenced anywhere in the process address space. For huge applications, it can take a few minutes to complete. This command is only available in Windows XP and later versions of Windows.

The **!heap -x** command searches for a heap block containing a given address. If the **-v** option is used, this command will additionally search the entire virtual memory space of the current process for pointers to this heap block. This command is only available in Windows XP and later versions of Windows.

The **!heap -p** command displays various forms of page heap information. Before using **!heap -p**, you must enable the page heap for the target process. This is done through the Global Flags (gflags.exe) utility. To do this, start the utility, fill in the name of the target application in the **Image File Name** text box, select **Image File Options** and **Enable page heap**, and click **Apply**. Alternatively, you can start the Global Flags utility from a Command Prompt window by typing **gflags /i xxx.exe +hpa**, where *xxx.exe* is the name of the target application.

The **!heap -p -t[c|s]** commands are not supported beyond Windows XP. Use the [UMDH](#) tool provided with the debugger package to obtain similar results.

The **!heap -srch** command displays those heap entries that contain a certain specified pattern.

The **!heap -flt** command limits the display to only heap allocations of a specified size.

The **!heap -stat** command displays heap usage statistics.

Here is an example of the standard **!heap** command:

```
0:000> !ntsdexts.heap -a

21 leaks detected.

```

The table in this example contains all 21 leaks found.

Here is an example of the **!heap -x** command:

```

0:011> !heap 002057b8 -x
## Entry      User      Heap      Segment      Size  PrevSize  Flags
002057a8  002057b0  00170000  00170640      58      58  busy extra

```

Here is an example of the **!heap -x -v** command:

```

1:0:011> !heap 002057b8 -x -v
## 1:Entry      User      Heap      Segment      Size  PrevSize  Flags
002057a8  002057b0  00170000  00170640      58      58  busy extra

Search VM for address range 002057a8 - 002057ff : 00205990 (002057d0),

```

In this example, there is a pointer to this heap block at address 0x00205990.

Here is an example of the **!heap -flt s** command:

```

0:001>!heap -flt s 0x50

```

This will display all of the allocations of size 0x50.

Here is an example of the **!heap -flt r** command:

```
0:001>!heap -flt r 0x50 0x80
```

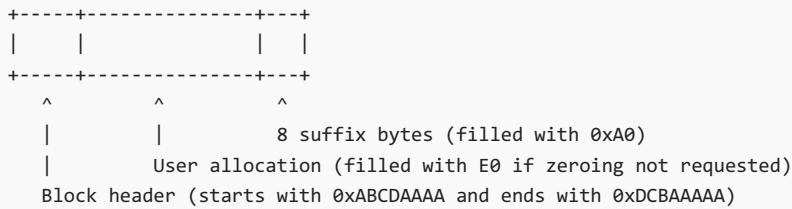

This will display each allocation whose size is between 0x50 and 0x7F.

Here is an example of the **!heap -srch** command.

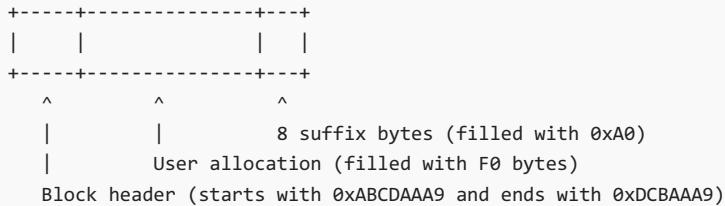

```
0:001> !heap -srch 77176934
 _HEAP @ 00090000
 in HEAP_ENTRY: Size : Prev Flags - UserPtr UserSize - state
 00099A48: 0018 : 0005 [01] - 00099A50 (000000B8) - (busy)
    ole32!CALLFRAME_CACHE<INTERFACE_HELPER_CLSID>::`vftable'
 _HEAP @ 00090000
 in HEAP_ENTRY: Size : Prev Flags - UserPtr UserSize - state
 00099B58: 0018 : 0005 [01] - 00099B60 (000000B8) - (busy)
    ole32!CALLFRAME_CACHE<INTERFACE_HELPER_CLSID>::`vftable'
```

The following diagrams show the arrangement of heap blocks.

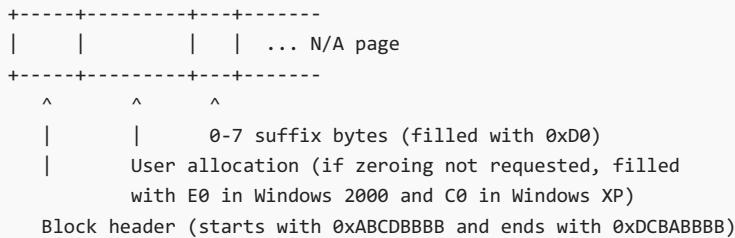

Light page heap block -- allocated:

Light page heap block -- freed:

Full page heap block -- allocated:

Full page heap block -- freed:

```
+-----+-----+-----+
|       |       |   ... N/A page
+-----+-----+-----+
^     ^     ^
|       |   0-7 suffix bytes (filled with 0xD0)
|       User allocation (filled with F0 bytes)
Block header (starts with 0xABCDDBBA and ends with 0xDCBABBBA)
```

To see the stack trace of the allocation or the freeing of a heap block or full page heap block, use **dt DPH_BLOCK_INFORMATION** with the header address, followed by **dds** with the block's **StackTrace** field.

[Send comments about this topic to Microsoft](#)

!help

5/31/2017 • 1 min to read • [Edit Online](#)

The **!help** extension displays help text that describes the extension commands exported from the extension DLL.

Do not confuse this extension command with the **? (Command Help)** or **.help (Meta-Command Help)** commands.

```
![ExtensionDLL.]help [-v] [CommandName]
```

Parameters

ExtensionDLL

Displays help for the specified extension DLL. Type the name of an extension DLL without the .dll file name extension. If the DLL file is not in the extension search path (as displayed by using **.chain (List Debugger Extensions)**), include the path to the DLL file. For example, to display help for uext.dll, type **!uext.help** or **!Path\winext\uext.help**.

If you omit the *ExtensionDLL*, the debugger will display the help text for the first extension DLL in the list of loaded DLLs.

-v

Displays the most detailed help text available. This feature is not supported in all DLLs.

CommandName

Displays only the help text for the specified command. This feature is not supported in all DLLs or for all commands.

DLL

This extension is supported by most extension DLLs.

Remarks

Some individual commands will also display a help text if you use the **/?** or **-?** parameter with the command name.

[Send comments about this topic to Microsoft](#)

!homedir

5/31/2017 • 1 min to read • [Edit Online](#)

The **!homedir** extension sets the default directory used by the symbol server and the source server.

```
!homedir Directory
!homedir
```

Parameters

Directory

Specifies the new directory to use as the home directory.

DLL

Windows 2000	Dbghelp.dll
Windows XP and later	Dbghelp.dll

Remarks

If the **!homedir** extension is used with no argument, the current home directory is displayed.

The cache for a source server is located in the `src` subdirectory of the home directory. The downstream store for a symbol server defaults to the `sym` subdirectory of the home directory, unless a different location is specified.

When WinDbg is started, the home directory is the directory where Debugging Tools for Windows was installed.

The **!homedir** extension can be used to change this value.

[Send comments about this topic to Microsoft](#)

!hstring

5/31/2017 • 1 min to read • [Edit Online](#)

The **!hstring** extension displays the fields of an **HSTRING**. The last item in the display is the string itself.

```
!hstring Address
```

Parameters

Address

The address of an **HSTRING**.

Remarks

The **HSTRING** data type supports strings that have embedded NULL characters. However, the **!hstring** extension displays the string only up to the first NULL character. To see the entire string including the embedded NULL characters, use the [!hstring2](#) extension.

See also

[Windows Runtime Debugger Commands](#)

[!hstring2](#)

[!winrterr](#)

[Send comments about this topic to Microsoft](#)

!hstring2

5/31/2017 • 1 min to read • [Edit Online](#)

The **!hstring2** extension displays an entire **HSTRING** including any embedded NULL characters in the string itself.

```
!hstring2 Address
```

Parameters

Address

The address of an **HSTRING**.

See also

[Windows Runtime Debugger Commands](#)

!hstring

!winrterr

[Send comments about this topic to Microsoft](#)

!htrace

5/31/2017 • 2 min to read • [Edit Online](#)

The **!htrace** extension displays stack trace information for one or more handles.

User-Mode Syntax

```
!htrace [Handle [Max_Traces]]  
!htrace -enable [Max_Traces]  
!htrace -snapshot  
!htrace -diff  
!htrace -disable  
!htrace -?
```

Kernel-Mode Syntax

```
!htrace [Handle [Process [Max_Traces]]]  
!htrace -?
```

Parameters

Handle

Specifies the handle whose stack trace will be displayed. If *Handle* is 0 or omitted, stack traces for all handles in the process will be displayed.

Process

(Kernel mode only) Specifies the process whose handles will be displayed. If *Process* is 0 or omitted, then the current process is used. In user mode, the current process is always used.

Max_Traces

Specifies the maximum number of stack traces to display. In user mode, if this parameter is omitted, then all the stack traces for the target process will be displayed.

-enable

(User mode only) Enables handle tracing and takes the first snapshot of the handle information to use as the initial state by the **-diff** option.

-snapshot

(User mode only) Takes a snapshot of the current handle information to use as the initial state by the **-diff** option.

-diff

(User mode only) Compares current handle information with the last snapshot of handle information that was taken. Displays all handles that are still open.

-disable

(User mode only; Windows Server 2003 and later only) Disables handle tracing. In Windows XP, handle tracing can be disabled only by terminating the target process.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll Ntsdexts.dll

Additional Information

For information about handles, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.) To display further information about a specific handle, use the **!handle** extension.

Remarks

Before **!htrace** can be used, handle tracing must be enabled. One way to enable handle tracing is to enter the **!htrace -enable** command. When handle tracing is enabled, stack trace information is saved each time the process opens a handle, closes a handle, or references an invalid handle. It is this stack trace information that **!htrace** displays.

Note You can also enable handle tracing by activating Application Verifier for the target process and selecting the **Handles** option.

Some of the traces reported by **!htrace** may be from a different process context. In this case, the return addresses may not resolve properly in the current process context, or may resolve to the wrong symbols.

The following example displays information about all handles in process 0x81400300:

```
kd> !htrace 0 81400300
Process 0x81400300
ObjectTable 0xE10CCF60

!imggp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!imggp** extension displays the global pointer (GP) directory entry value for a 64-bit image.

```
!imggp Address
```

Parameters

Address

Specifies the base address of the image.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

[Send comments about this topic to Microsoft](#)

!imgreloc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!imgreloc** extension displays the addresses of each loaded module and indicates their former addresses before they were relocated.

```
!imgreloc Address
```

Parameters

Address

Specifies the base address of the image.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

Here is an example:

```
0:000> !imgreloc 00400000
00400000 Prymes - at preferred address
010e0000 appvcore - RELOCATED from 00400000
5b2f0000 verifier - at preferred address
5d160000 ShimEng - at preferred address
```

[Send comments about this topic to Microsoft](#)

!kuser

5/31/2017 • 1 min to read • [Edit Online](#)

The **!kuser** extension displays the shared user-mode page (KUSER_SHARED_DATA).

```
!kuser
```

DLL

Windows 2000	Kdextx86.dll Ntsdexts.dll
Windows XP and later	Exts.dll

Remarks

The KUSER_SHARED_DATA page gives resource and other information about the user who is currently logged on.

Here is an example. Note that, in this example, the tick count is displayed in both its raw form and in a more user-friendly form, which is in parentheses. The user-friendly display is available only in Windows XP and later.

```
kd> !kuser
_KUSER_SHARED_DATA at 7ffe0000
TickCount:    fa00000 * 00482006 (0:20:30:56.093)
TimeZone Id: 2
ImageNumber Range: [14c .. 14c]
Crypto Exponent: 0
SystemRoot: 'F:\WINDOWS'
```

[Send comments about this topic to Microsoft](#)

!list

5/31/2017 • 3 min to read • [Edit Online](#)

The **!list** extension executes the specified debugger commands repeatedly, once for every element in a linked list.

```
!list -t [Module!]Type.Field -x "Commands" [-a "Arguments"] [Options] StartAddress
!list " -t [Module!]Type.Field -x \"Commands\" [-a \"Arguments\"] [Options] StartAddress "
!list -h
```

Parameters

Module

An optional parameter specifying the module that defines this structure. If there is a chance that *Type* may match a valid symbol in a different module, you should include *Module* to eliminate the ambiguity.

Type

Specifies the name of a data structure.

Field

Specifies the field containing the list link. This can actually be a sequence of fields separated by periods (in other words, **Type.Field.Subfield.Subsubfield**, and so on).

-x "Commands"

Specifies the commands to execute. This can be any combination of debugger commands. It must be enclosed in quotation marks. If multiple commands are specified, separate them with semicolons, enclose the entire collection of **!list** arguments in quotation marks, and use an escape character (\) before each quotation mark inside these outer quotation marks. If *Commands* is omitted, the default is [dp \(Display Memory\)](#).

-a "Arguments"

Specifies the arguments to pass to the *Commands* parameter. This must be enclosed in quotation marks.

Arguments can be any valid argument string that would normally be allowed to follow this command, except that *Arguments* cannot contain quotation marks. If the pseudo-register **\$extret** is included in *Commands*, the **-a "Arguments"** parameter can be omitted.

Options

Can be any number of the following options:

-e

Echoes the command being executed for each element.

-m Max

Specifies the maximum number of elements to execute the command for.

StartAddress

Specifies the address of the first data structure. This is the address at the top of the structure, not necessarily the address of the link field.

-h

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

The **!list** extension will go through the linked list and issue the specified command once for each list element.

The pseudo-register **\$extret** is set to the value of the list-entry address for each list element. For each element, the command string *Commands* is executed. This command string can reference this pseudo-register using the **\$extret** syntax. If this does not appear in the command string, the value of the list-entry address is appended to the end of the command string before execution. If you need to specify where this value should appear in your command, you must specify this pseudo-register explicitly.

This command sequence will run until the list terminates in a null pointer, or terminates by looping back onto the first element. If the list loops back onto a later element, this command will not stop. However, you can stop this command at any time by using **CTRL+C** in KD and CDB, or **Debug | Break** or **CTRL+BREAK** in WinDbg.

Each time a command is executed, the address of the current structure will be used as the *default address* if the command being used has optional address parameters.

Following are two examples of how to use this command in user mode. Note that kernel mode usage is also possible but follows a different syntax.

As a simple example, assume that you have a structure whose type name is **MYTYPE**, and which has links within its **.links.Flink** and **.links.Blink** fields. You have a linked list that begins with the structure at 0x6BC000. The following extension command will go through the list and for each element will execute a **dd** L2 command. Because no address is being specified to the **dd** command, it will take the address of the list head as the desired address. This causes the first two DWORDs in each structure to be displayed.

```
0:000> !list -t MYTYPE.links.Flink -x "dd" -a "L2" 0x6bc00
```

As a more complex example, consider the case of using **\$extret**. It follows the list of type **_LIST_ENTRY** at **RtlCriticalSectionList**. For each element, it displays the first four DWORDS, and then displays the **_RTL_CRITICAL_SECTION_DEBUG** structure located at an offset of eight bytes prior to the **Flink** element of the list entry.

```
0:000> !list "-t ntdll!_LIST_ENTRY.Flink -e -x \"dd @$extret 14; dt ntdll!_RTL_CRITICAL_SECTION_DEBUG  
@$extret-0x8\" ntdll!RtlCriticalSectionList"

[Send comments about this topic to Microsoft](#)

The **!lmi** extension displays detailed information about a module.

!lmi Module

Parameters

Module

Specifies a loaded module, either by name or by base address.

DLL

Windows 2000	Dbghelp.dll
Windows XP and later	Dbghelp.dll

Remarks

Module addresses can be determined by using the [!m \(List Loaded Modules\)](#) command.

The **!lmi** extension analyzes the module headers and displays a formatted summary of the information therein. If the module headers are paged out, an error message is displayed. To see a more extensive display of header information, use the [!dh](#) extension command.

This command shows a number of fields, each with a different title. Some of these titles have specific meanings:

- The **Image Name** field shows the name of the executable file, including the extension. Typically, the full path is included in user mode but not in kernel mode.
- The **Module** field shows the *module name*. This is usually just the file name without the extension. In a few cases, the module name differs significantly from the file name.
- The **Symbol Type** field shows information about the debugger's attempts to load this module's symbols. For an explanation of the various status values, see [Symbol Status Abbreviations](#). If symbols have been loaded, the symbol file name follows this.
- The first address in the module is shown as **Base Address**. The size of the module is shown as **Size**. Thus, if **Base Address** is "faab4000" and **Size** is "2000", the module extends from 0xFAAB4000 to 0xFAAB5FFF, inclusive.

Here is an example:

```
0:000> lm
start   end     module name
00400000 0042d000  Prymes      C (pdb symbols)          Prymes.pdb
77e80000 77f35000  KERNEL32    (export symbols)        C:\WINNT\system32\KERNEL32.dll
77f80000 77ffb000  ntdll       (export symbols)        ntdll.dll

0:000> !lmi 00400000
Loaded Module Info: [00400000]
    Module: Prymes
    Base Address: 00400000
    Image Name: Prymes.exe
    Machine Type: 332 (I386)
    Time Stamp: 3c76c346 Fri Feb 22 14:16:38 2002
    Size: 2d000
    CheckSum: 0
    Characteristics: 230e stripped
    Debug Data Dirs: Type Size     VA  Pointer
                      MISC 110,     0,   77a00 [Data not mapped]
    Symbol Type: EXPORT - PDB not found
    Load Report: export symbols
```

For an explanation of the abbreviations shown on the **Characteristics** line of this example, see [Symbol Status Abbreviations](#).

[Send comments about this topic to Microsoft](#)

!mui

5/31/2017 • 1 min to read • [Edit Online](#)

The **!mui** extension displays the Multilingual User Interface (MUI) cache information. The implementation of MUI was improved in Windows Vista. As a result, the behavior of this extension on earlier implementations is undefined.

```
!mui -c
!mui -s
!mui -r ModuleAddress
!mui -i
!mui -f
!mui -t
!mui -u
!mui -d ModuleAddress
!mui -e ModuleAddress
!mui -?
```

Parameters

-c

Causes the output to include the language identifier (ID), a pointer to the module, a pointer to the resource configuration data, and a pointer to the associated MUI DLL for each module.

-s

(Kernel Mode Only) Causes the display to include the full file paths for the module and associated MUI DLL for each module.

-r ** ModuleAddress**

Causes the resource configuration data for the module at *ModuleAddress* to be displayed. This includes the file type, the checksum value, and the resource types.

-i

Causes the output to include the installed and licensed MUI languages and their associated information.

-f

Causes the output to include the loader merged language fallback list.

-t

Causes the output to include the thread preference language.

-u

Causes the output to include the current thread user UI language setting.

-d ** ModuleAddress**

Causes the output to include contained resources for the module at *ModuleAddress*.

-e ** ModuleAddress**

Causes the output to include contained resource types for the module at *ModuleAddress*.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows XP	Unavailable
Windows Vista and later	Exts.dll

Additional Information

For information about MUI and resource configuration data format, see the Microsoft Windows SDK documentation.

[Send comments about this topic to Microsoft](#)

!net_send

5/31/2017 • 1 min to read • [Edit Online](#)

The **!net_send** extension sends a message over a local network.

```
!net_send SendingMachine TargetMachine Sender Message
```

Parameters

SendingMachine

Specifies the computer that will process the command. It is recommended that this be the name of the computer that the debugger is running on, since your network configuration may refuse to send the message otherwise. *SendingMachine* should not include leading backslashes (\).

TargetMachine

Specifies the computer to which the message will be sent. *TargetMachine* should not include leading backslashes (\).

Sender

Specifies the sender of the message. It is recommended that *Sender* be identical to *SendingMachine*, since your network configuration may refuse to send the message otherwise. When the message is displayed, this string will be identified as the sender of the message.

Message

Specifies the message itself. All text after the *Sender* parameter will be treated as part of *Message*, including spaces and quotation marks, although a **semicolon** will terminate *Message* and begin a new command.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

[Send comments about this topic to Microsoft](#)

!obja

5/31/2017 • 1 min to read • [Edit Online](#)

The **!obja** extension displays the attributes of an object in the object manager.

```
!obja Address
```

Parameters

Address

Specifies the hexadecimal address of the object header you want to examine.

DLL

Windows 2000	Ext.dll Kdextx86.dll
Windows XP and later	Ext.dll

Additional Information

For information about objects and the object manager, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The attributes pertaining to the specified object are listed. Valid attributes are:

```
#define OBJ_INHERIT          0x00000002L
#define OBJ_PERMANENT         0x00000010L
#define OBJ_EXCLUSIVE          0x00000020L
#define OBJ_CASE_INSENSITIVE    0x00000040L
#define OBJ_OPENIF              0x00000080L
#define OBJ_OPENLINK             0x00000100L
#define OBJ_VALID_ATTRIBUTES     0x000001F2L
```

Here is an example:

```
kd> !obja 80967768
Obja +80967768 at 80967768:
    OBJ_INHERIT
    OBJ_PERMANENT
    OBJ_EXCLUSIVE
```

[Send comments about this topic to Microsoft](#)

!owner

5/31/2017 • 1 min to read • [Edit Online](#)

The **!owner** extension displays the owner of a module or function.

```
!owner [Module[!Symbol]]
```

Parameters

Module

Specifies the module whose owner is desired. An asterisk (*) at the end of *Module* represents any number of additional characters.

Symbol

Specifies the symbol within *Module* whose owner is desired. An asterisk (*) at the end of *Symbol* represents any number of additional characters. If *Symbol* is omitted, the owner of the entire module is displayed.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Remarks

If no parameters are used and a fault has occurred, **!owner** will display the name of the owner of the faulting module or function.

When you pass a module or function name to the **!owner** extension, the debugger displays the word **Followup** followed by the name of owner of the specified module or function.

For this extension to display useful information, you must first create a triage.ini file containing the names of the module and function owners.

For details on the triage.ini file and an example of the **!owner** extension, see [Specifying Module and Function Owners](#).

[Send comments about this topic to Microsoft](#)

!peb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!peb** extension displays a formatted view of the information in the process environment block (PEB).

```
!peb [PEB-Address]
```

Parameters

PEB-Address

The hexadecimal address of the process whose PEB you want to examine. (This is not the address of the PEB as derived from the kernel process block for the process.) If *PEB-Address* is omitted in user mode, the PEB for the current process is used. If it is omitted in kernel mode, the PEB corresponding to the current [process context](#) is displayed.

DLL

Windows 2000	Kdextx86.dll Ntsdexts.dll
Windows XP and later	Exts.dll

Additional Information

For information about process environment blocks, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

The PEB is the user-mode portion of Microsoft Windows process control structures.

If the **!peb** extension with no argument gives you an error in kernel mode, you should use the **!process** extension to determine the PEB address for the desired process. Make sure your [process context](#) is set to the desired process, and then use the PEB address as the argument for **!peb**.

The exact output displayed depends on the Windows version and on whether you are debugging in kernel mode or user mode. The following example is taken from a kernel debugger attached to a Windows Server 2003 target:

```
kd> !peb
PEB at 7ffdf000
  InheritedAddressSpace: No
  ReadImageFileExecOptions: No
  BeingDebugged: No
  ImageBaseAddress: 4ad00000

    APPDATA=D:\Documents and Settings\UserTwo\Application Data
    CLIENTNAME=Console
...
windir=D:\WINDOWS
```

The similar **!teb** extension displays the thread environment block.

[Send comments about this topic to Microsoft](#)

!rebase

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rebase** extension searches in a rebase.log file for a specified address or symbol.

```
!rebase [-r] Address [Path]
!rebase Symbol [Path]
!rebase -stack [Path]
!rebase -?
```

Parameters

-r

Attempts to load any module found in rebase.log.

Address

Specifies an address in standard hexadecimal format. The extension will search for DLLs near this address.

Path

Specifies the file path to the rebase.log. If *Path* is not specified, then the extension tries to guess the path to the rebase.log or, failing that, tries to read a rebase.log file from the current working directory.

Symbol

Specifies the symbol or image name. The extension will search for DLLs that contain this substring.

-stack

Displays all modules in the current stack.

-?

Displays a brief help text for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Ext.dll

[Send comments about this topic to Microsoft](#)

!rtlavl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!rtlavl** extension displays the entries of an RTL_AVL_TABLE structure.

```
!rtlavl Address [Module!Type]  
!rtlavl -?
```

Parameters

Address

Specifies the address of the RTL_AVL_TABLE to display.

Module

Specifies the module in which the data structure is defined.

Type

Specifies the name of a data structure.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

Use the [!gentable](#) extension to display AVL tables.

Remarks

Including the *Module!Type* option causes each entry in the table to be interpreted as having the given type.

The display can be interrupted at any time by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD or CDB).

[Send comments about this topic to Microsoft](#)

!sd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!sd** extension displays the security descriptor at the specified address.

Syntax

```
!sd Address [Flags]
```

Parameters

Address

Specifies the hexadecimal address of the SECURITY_DESCRIPTOR structure.

Flags

If this is set to 1, the friendly name is displayed. This includes the security identifier (SID) type, as well as the domain and user name for the SID.

DLL

Exts.dll

Additional Information

For an application and an example of this command, see [Determining the ACL of an Object](#). For information about security descriptors, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. Also see [!sid](#) and [!acl](#).

Remarks

Here is an example:

```
kd> !sd e1a96a80 1
->Revision: 0x1
->Sbz1 : 0x0
->Control : 0x8004
    SE_DACL_PRESENT
    SE_SELF_RELATIVE

->Group : S-1-5-21-518066528-515770016-299552555-513 (Group: MYDOMAIN\Domain Users)
->Dacl :
->Dacl : ->AclRevision: 0x2
->Dacl : ->Sbz1 : 0x0
->Dacl : ->AclSize : 0x40
->Dacl : ->AceCount : 0x2
->Dacl : ->Sbz2 : 0x0
->Dacl : ->Ace[0]: ->AceType: ACCESS_ALLOWED_ACE_TYPE
->Dacl : ->Ace[0]: ->AceFlags: 0x0
->Dacl : ->Ace[0]: ->AceSize: 0x24
->Dacl : ->Ace[0]: ->Mask : 0x001f0003
->Dacl : ->Ace[0]: ->SID: S-1-5-21-518066528-515770016-299552555-2981724 (User: MYDOMAIN\myuser)

->Dacl : ->Ace[1]: ->AceType: ACCESS_ALLOWED_ACE_TYPE
->Dacl : ->Ace[1]: ->AceFlags: 0x0
->Dacl : ->Ace[1]: ->AceSize: 0x14
->Dacl : ->Ace[1]: ->Mask : 0x001f0003
->Dacl : ->Ace[1]: ->SID: S-1-5-18 (Well Known Group: NT AUTHORITY\SYSTEM)

->Sacl : is NULL
```

[Send comments about this topic to Microsoft](#)

!sid

5/31/2017 • 1 min to read • [Edit Online](#)

The **!sid** extension displays the security identifier (SID) at the specified address.

Syntax

```
!sid Address [Flags]
```

Parameters

Address

Specifies the address of the SID structure.

Flags

If this is set to 1, the SID type, domain, and user name for the SID is displayed.

If this is set to 1, the friendly name is displayed. This includes the SID type, as well as the domain and user name for the SID.

DLL

Exts.dll

Additional Information

For information about SIDs, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, or *Microsoft Windows Internals* by Mark Russinovich and David Solomon. Also see [!sd](#) and [!acl](#).

Remarks

Here are two examples, one without the friendly name shown, and one with:

```
kd> !sid 0xe1bf35b8
SID is: S-1-5-21-518066528-515770016-299552555-513

kd> !sid 0xe1bf35b8 1
SID is: S-1-5-21-518066528-515770016-299552555-513 (Group: MYGROUP\Domain Users)
```

[Send comments about this topic to Microsoft](#)

!slist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!slist** extension displays a singly-linked list (SList).

```
!slist Address [ Symbol [Offset] ]  
!slist -?
```

Parameters

Address

Specifies the address of the SLIST_HEADER.

Symbol

Specifies the data type to use for display. If *Symbol* is specified, the debugger will assume that each node of the SList is an instance of this data type when displaying it.

Offset

Specifies the byte offset of the SList pointer within the structure.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Exts.dll

Remarks

If you know the nature of the linked structures, the *Symbol* and *Offset* parameters are very useful. To see the difference, here are two examples; the first omits the *Symbol* and *Offset* parameters, while the second includes them.

```
0:000> !slist ListHead

[Send comments about this topic to Microsoft](#)

!std_map

5/31/2017 • 1 min to read • [Edit Online](#)

The **!std_map** extension displays the entries of a std::map tree.

```
!std_map Address [Module!Type [TypeSize]]  
!std_map -?
```

Parameters

Address

Specifies the address of the std::map tree to display.

Module

Specifies the module in which the data structure is defined.

Type

Specifies the name of a data structure. This must be expressed in *Module!std::pair<Type1,Type2>* form. If the *TypeSize* parameter is used, this parameter must be enclosed in quotation marks.

TypeSize

Specifies the size of the data structure to make the symbols unambiguous.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

To display other Standard Template Library (STL) defined templates, see [!stl](#).

Remarks

Including the *Module!Type* option causes each entry in the table to be interpreted as having the given type.

Use [dt -ve \(Module!std::pair<Type1,Type2>\)](#) to display possible sizes.

[Send comments about this topic to Microsoft](#)

!stl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!stl** extension displays some of the known Standard Template Library (STL) templates.

```
!stl [Options] Template
!stl -?
```

Parameters

Options

May include any of the following possibilities:

-v

Causes detailed output to be displayed.

-V

Causes more detailed output to be displayed, such as information on the progress of the extension, including when certain functions are called and returned.

Template

Specifies the name of the template to be displayed.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Exts.dll

Remarks

The verbose options will only take effect if the debugger's verbose mode is enabled.

This extension currently supports STL templates of the following types: `string`, `wstring`, `vector<string>`, `vector<wstring>`, `list<string>`, `list<wstring>`, and pointers to any of the preceding types.

[Send comments about this topic to Microsoft](#)

!str

5/31/2017 • 1 min to read • [Edit Online](#)

The **!str** extension displays an ANSI_STRING or OEM_STRING structure.

```
!str Address
```

Parameters

Address

Specifies the hexadecimal address of the ANSI_STRING or OEM_STRING structure.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about ANSI_STRING structures, see the Microsoft Windows SDK documentation.

Remarks

ANSI strings are counted 8-bit character strings, as defined in the following structure:

```
typedef struct _STRING {
    USHORT Length;
    USHORT MaximumLength;
    PCHAR Buffer;
} STRING;
typedef STRING ANSI_STRING;
typedef STRING OEM_STRING;
```

If the string is null-terminated, **Length** does not include the trailing null.

[Send comments about this topic to Microsoft](#)

!sym

5/31/2017 • 1 min to read • [Edit Online](#)

The **!sym** extension controls noisy symbol loading and symbol prompts.

```
!sym
!sym noisy
!sym quiet
!sym prompts
!sym prompts off
```

Parameters

noisy

Activates noisy symbol loading.

quiet

Deactivates noisy symbol loading.

prompts

Allows authentication dialog boxes to appear when SymSrv receives an authentication request.

prompts off

Suppresses all authentication dialog boxes when SymSrv receives an authentication request. This may result in SymSrv being unable to access symbols over the internet.

DLL

Windows 2000	Dbghelp.dll
Windows XP and later	Dbghelp.dll

Remarks

If the **!sym** extension is used with no arguments, the current state of noisy symbol loading and symbol prompting is displayed.

The **!sym noisy** and **!sym quiet** extensions control noisy symbol loading. For details and for other methods of displaying and changing this option, see [SYMOPT_DEBUG](#).

The **!sym prompts** and **!sym prompts off** extensions control whether authentication dialogs are displayed when SymSrv encounters an authentication request. These commands must be followed by [.reload \(Reload Module\)](#) for them to take effect. Authentication requests may be sent by proxy servers, internet firewalls, smart card readers, and secure websites. For details and for other methods of changing this option, see [Firewalls and Proxy Servers](#).

Note Noisy symbol loading should not be confused with noisy source loading -- that is controlled by the [.srcnoisy \(Noisy Source Loading\)](#) command.

Send comments about this topic to [Microsoft](#)

!symsrv

5/31/2017 • 1 min to read • [Edit Online](#)

The **!symsrv** extension closes the symbol server client.

```
!symsrv close
```

DLL

Windows 2000	Dbghelp.dll
Windows XP and later	Dbghelp.dll

Remarks

The **!symsrv close** extension will close any active symbol server client.

This can be useful if you need to re-synchronize your connection.

If you have previously refused an internet authentication request, you will need to use **!symsrv close** to reconnect to the symbol store. See [Firewalls and Proxy Servers](#) for details.

[Send comments about this topic to Microsoft](#)

!teb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!teb** extension displays a formatted view of the information in the thread environment block (TEB).

```
!teb [TEB-Address]
```

Parameters

TEB-Address

The hexadecimal address of the thread whose TEB you want to examine. (This is not the address of the TEB as derived from the kernel thread block for the thread.) If *TEB-Address* is omitted in user mode, the TEB for the current thread is used. If it is omitted in kernel mode, the TEB corresponding to the current [register context](#) is displayed.

DLL

Exts.dll

Additional Information

For information about thread environment blocks, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

The TEB is the user-mode portion of Microsoft Windows thread control structures.

If the **!teb** extension with no argument gives you an error in kernel mode, you should use the **!process** extension to determine the TEB address for the desired thread. Make sure your [register context](#) is set to the desired thread, and then use the TEB address as the argument for **!teb**.

Here is an example of this command's output in user mode:

```
0:001> ~
0  id: 324.458  Suspend: 1 Teb 7ffde000 Unfrozen
. 1  id: 324.48c  Suspend: 1 Teb 7ffdd000 Unfrozen

0:001> !teb

  ExceptionList:    76ffdc
  Stack Base:      770000
  Stack Limit:     76f000
  SubSystemTib:    0
  FiberData:       1e00
  ArbitraryUser:   0
  Self:            7ffdd000
  EnvironmentPtr:  0
  ClientId:        324.48c
  Real ClientId:   324.48c
  RpcHandle:       0
  Tls Storage:     0
  PEB Address:     7ffdf000
  LastErrorValue:   0
  LastStatusValue:  0
  Count Owned Locks: 0
  HardErrorsMode:   0
```

The similar **!peb** extension displays the process environment block.

[Send comments about this topic to Microsoft](#)

!tls

5/31/2017 • 1 min to read • [Edit Online](#)

The **!tls** extension displays a thread local storage (TLS) slot.

```
!tls Slot [TEB]
```

Parameters

Slot

Specifies the TLS slot. This can be any value between 0 and 1088 (decimal). If *Slot* is -1, all slots are displayed.

TEB

Specifies the thread environment block (TEB). If this is 0 or omitted, the current thread is used.

DLL

Windows 2000	Unavailable
Windows XP and later	Exts.dll

Remarks

Here is an example:

```
0:000> !tls -1
TLS slots on thread: c08.f54
0x0000 : 00000000
0x0001 : 003967b8
0:000> !tls 0
c08.f54: 00000000
```

[Send comments about this topic to Microsoft](#)

!token

5/31/2017 • 3 min to read • [Edit Online](#)

The **!token** extension displays a formatted view of a security token object.

Kernel-Mode Syntax:

```
!token [-n] [Address]  
!token -?
```

User-Mode Syntax:

```
!token [-n] [Handle]  
!token -?
```

Parameters

Address

(Kernel mode only) Specifies the address of the token to be displayed. If this is 0 or omitted, the token for the active thread is displayed.

Handle

(User mode only) Specifies the handle of the token to be displayed. If this is 0 or omitted, the token associated with the target thread is displayed.

-n

(User mode only) Causes the display to include the friendly name. This includes the security identifier (SID) type, as well as the domain and user name for the SID. This option cannot be used when you are debugging LSASS.

-?

Displays help text for this extension.

DLL

Exts.dll

The **!token** command is available in kernel-mode and live user-mode debugging. It cannot be used on user-mode dump files.

Additional Information

For information about the kernel-mode TOKEN structure, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. For information about the user-mode TOKEN structure, see the Microsoft Windows SDK documentation.

Remarks

The TOKEN structure is a security object type that represents an authenticated user process. Every process has an assigned token, which becomes the default token for each thread of that process. However, an individual thread can be assigned a token that overrides this default.

You can get the token address from the output of [!process](#). To display a list of the individual fields of the TOKEN structure, use the **dt nt!_TOKEN** command.

Here is an example:

```
kd> !process 81464da8 1

[Send comments about this topic to Microsoft](#)

!tp

5/31/2017 • 2 min to read • [Edit Online](#)

The **!tp** extension displays thread pool information.

```
!tp pool Address [Flags]
!tp tqueue Address [Flags]
!tp ItemType Address [Flags]
!tp ThreadType [Address]
!tp stats Address [Flags]
!tp wfac Address
!tp wqueue Address Priority Node
!tp -?
```

Parameters

pool **** *Address*

Causes the entire thread pool at *Address* to be displayed. If *Address* is 0, then all thread pools will be displayed.

tqueue **** *Address*

Causes the active timer queue at *Address* to be displayed.

ItemType *Address*

Causes the specified thread pool item to be displayed. *Address* specifies the address of the item. *ItemType* specifies the type of the item; this can include any of the following possibilities:

obj

A generic pool item (such as an IO item) will be displayed.

timer

A timer item will be displayed.

wait

A wait item will be displayed.

work

A work item will be displayed.

ThreadType [*Address*]

Causes threads of the specified type to be displayed. If *Address* is included and nonzero, then only the thread at this address is displayed. If *Address* is 0, all threads matching *ThreadType* are displayed. If *Address* is omitted, only the threads matching *ThreadType* associated with the current thread are displayed. *ThreadType* specifies the type of the thread to be displayed; this can include any of the following possibilities:

waiter

A thread pool waiter thread will be displayed.

worker

A thread pool worker thread will be displayed.

stats [*Address*]

Causes the debug statistics of the current thread to be displayed. *Address* may be omitted, but if it is specified, it must equal -1 (negative one), to represent the current thread.

wfac ** Address**

(Windows 7 and later only) Causes the worker factory at *Address* to be displayed. The specified *Address* must be a valid nonzero address.

wqueue ** Address**

(Windows 7 and later only) Causes display of a work queue and NUMA node that match the following: a specified priority, a specified NUMA node, and the pool, at a specified address, to which the NUMA node belongs. *Address* specifies the address of the pool. When the **wqueue** parameter is used, it must be followed by *Address*, *Priority*, and *Node*.

Priority

(Windows 7 and later only) Specifies the priority levels of the work queues to be displayed. *Priority* can be any of the following values:

0

Work queues with high priority are displayed.

1

Work queues with normal priority are displayed.

2

Work queues with low priority are displayed.

-1

All work queues are displayed.

Node

(Windows 7 and later only) Specifies a NUMA node belonging to the pool specified by *Address*. If *Node* is -1 (negative one), all NUMA nodes are displayed.

Flags

Specifies what the display should contain. This can be a sum of any of the following bit values (the default is 0x0):

Bit 0 (0x1)

Causes the display to be single-line output. This bit value has no effect on the output when an *ItemType* is displayed.

Bit 1 (0x2)

Causes the display to include member information.

Bit 2 (0x4)

This flag is relevant only when the **pool** option is used. In Windows XP, Windows Server 2003, Windows Vista, and Windows Server 2008, this flag causes the display to include the pool work queue. In Windows 7 and later, this flag causes the display to include all the pool's work queues that are at normal priority, and all NUMA nodes.

-?

Displays a brief help text for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Ext.dll

Additional Information

For information about thread pooling, see the Microsoft Windows SDK documentation.

[Send comments about this topic to Microsoft](#)

!triage

5/26/2017 • 1 min to read • [Edit Online](#)

The **!triage** extension command is obsolete. Use **!analyze** instead.

[Send comments about this topic to Microsoft](#)

!ustr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ustr** extension displays a UNICODE_STRING structure.

```
!ustr Address
```

Parameters

Address

Specifies the hexadecimal address of the UNICODE_STRING structure.

DLL

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more information about UNICODE_STRING structures, see the Microsoft Windows SDK documentation.

Remarks

Unicode strings are counted 16-bit character strings, as defined in the following structure:

```
typedef struct _UNICODE_STRING {  
    USHORT Length;  
    USHORT MaximumLength;  
    PWSTR Buffer;  
} UNICODE_STRING;
```

If the string is null-terminated, **Length** does not include the trailing null.

Most Win32 character string arguments are converted to Unicode strings before any real work is done.

[Send comments about this topic to Microsoft](#)

!version

5/31/2017 • 1 min to read • [Edit Online](#)

The **!version** extension displays the version information for the extension DLL.

This extension command should not be confused with the [version \(Show Debugger Version\)](#) command.

```
![ExtensionDLL.]version
```

Parameters

ExtensionDLL

Specifies the extension DLL whose version number is to be displayed.

DLL

This extension is available in most extension DLLs.

Remarks

If the extension DLL version does not match the debugger version, error messages will be displayed.

This extension command will not work on Windows XP and later versions of Windows. To display version information, use the [version \(Show Debugger Version\)](#) command.

The original purpose of this extension was to ensure that the DLL version matched the target version, since a mismatch would result in inaccurate results for many extensions. Newer DLLs are no longer restricted to working with only one version of Windows, so this extension is obsolete.

[Send comments about this topic to Microsoft](#)

!winrterr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!winrterr** sets the debugger reporting mode for Windows Runtime errors.

```
!winrterr Mode  
!winrterr
```

Parameters

Mode

The following table describes the possible values for *Mode*.

VALUE	DESCRIPTION
report	When a Windows Runtime error occurs, the error and related text are displayed in the debugger, but execution continues. This is the default mode.
break	When a Windows Runtime error occurs, the error and related text are displayed in the debugger, and execution stops.
quiet	When a Windows Runtime error occurs, nothing is displayed in the debugger, and execution continues.

If *Mode* is omitted, **!winrterr** displays the current reporting mode. If the debugger has broken in as a result of a Windows Runtime error, the error and related text are also displayed.

Kernel-Mode Extensions

5/26/2017 • 1 min to read • [Edit Online](#)

This section of the reference describes extension commands that are primarily used during kernel-mode debugging.

The debugger will automatically load the proper version of these extension commands. Unless you have manually loaded a different version, you do not have to keep track of the DLL versions being used. See [Using Debugger Extension Commands](#) for a description of the default module search order. See [Loading Debugger Extension DLLs](#) for an explanation of how to load extension modules.

Each extension command reference page lists the DLLs that expose that command. Use the following rules to determine the proper directory from which to load this extension DLL:

- If your target computer is running Windows XP or a later version of Windows, use `winxp\Kdexts.dll`.

In addition, kernel-mode extensions that are not specific to any single operating system can be found in `winext\kext.dll`.

[Send comments about this topic to Microsoft](#)

!ahcache

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ahcache** extension displays the application compatibility cache.

```
!ahcache [Flags]
```

Parameters

Flags

Specifies the information to include in the display. This can be any combination of the following bits (the default is zero):

Bit 0 (0x1)

Displays the RTL_GENERIC_TABLE list instead of the LRU list.

Bit 4 (0x10)

Verbose display: includes all entry details, not just the names.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

[Send comments about this topic to Microsoft](#)

!alignmentfaults

5/31/2017 • 1 min to read • [Edit Online](#)

The **!alignmentfaults** extension displays all current type alignment faults by location and image, sorted by frequencies.

```
!alignmentfaults
```

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about alignment faults, see the Microsoft Windows SDK documentation.

Remarks

This is only available on checked builds.

[Send comments about this topic to Microsoft](#)

!analyzebugcheck

5/26/2017 • 1 min to read • [Edit Online](#)

The **!analyzebugcheck** extension command is obsolete. Use [!analyze](#) instead.

[Send comments about this topic to Microsoft](#)

!apc

5/31/2017 • 1 min to read • [Edit Online](#)

The **!apc** extension formats and displays the contents of one or more asynchronous procedure calls (APCs).

```
!apc
!apc proc Process
!apc thre Thread
!apc KAPC
```

Parameters

Process

Specifies the address of the process whose APCs are to be displayed.

Thread

Specifies the address of the thread whose APCs are to be displayed.

KAPC

Specifies the address of the kernel APC to be displayed.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about APCs, see the Windows Driver Kit (WDK) documentation and Microsoft Windows Internals by Mark Russinovich and David Solomon.

Remarks

Without any parameters, **!apc** displays all APCs.

Here is an example:

```
kd> !apc
*** Enumerating APCs in all processes
Process e0000000858ba8b0 System
Process e0000165fff86040 smss.exe
Process e0000165fff8c040 csrss.exe
Process e0000165fff4e1d0 winlogon.exe
Process e0000165fff101d0 services.exe
Process e0000165ffffa81d0 lsass.exe
Process e0000165fff201d0 svchost.exe
Process e0000165fff8e040 svchost.exe
Process e0000165fff3e040 svchost.exe
Process e0000165fff6e040 svchost.exe
Process e0000165fff24040 spoolsv.exe
Process e000000085666640 wmpiprvse.exe
Process e00000008501e520 wmpiprvse.exe
Process e0000000856db480 explorer.exe

Process e0000165fff51600 conime.exe
Process e000000085496340 taskmgr.exe
Process e000000085489c30 userinit.exe
```

[Send comments about this topic to Microsoft](#)

!apicerr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!apicerr** extension displays the local Advanced Programmable Interrupt Controller (APIC) error log.

```
!apicerr [Format]
```

Parameters

Format

Specifies the order in which to display the error log contents. This can be any one of the following values:

0x0

Displays the error log according to order of occurrence.

0x1

Displays the error log according to processor.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an x86-based or an x64-based target computer.

Additional Information

For information about APICs, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

[Send comments about this topic to Microsoft](#)

!arbinst

5/31/2017 • 1 min to read • [Edit Online](#)

The **!arbinst** extension displays information about a specified arbiter.

```
!arbinst Address [Flags]
```

Parameters

Address

Specifies the hexadecimal address of the arbiter to be displayed.

Flags

Specifies how much information to display for each arbiter. At present, the only flag is 0x100. If this flag is set, then the aliases are displayed.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

See also the [!arbiter](#) extension.

Remarks

For the arbiter specified, **!arbinst** displays each allocated range of system resources, some optional flags, the PDO attached to that range (in other words, the range's owner), and the service name of this owner (if known).

Here is an example:

```
kd> !arbinst e0000106002ee8e8
Port Arbiter "PCI I/O Port (b=02)" at e0000106002ee8e8
Allocated ranges:
 0000000000000000 - 0000000000001fff      00000000 <Not on bus>
 0000000000002000 - 00000000000020ff      P e0000000858bea20 (ql1280)
 0000000000003000 - ffffffffffffff      00000000 <Not on bus>
Possible allocation:
< none >
kd> !arbinst e0000106002ec458
Memory Arbiter "PCI Memory (b=02)" at e0000106002ec458
Allocated ranges:
 0000000000000000 - 00000000ebffff      00000000 <Not on bus>
 00000000effdef00 - 00000000effdefff      B e0000000858be560
 00000000effdf000 - 00000000effdffff      e0000000858bea20 (ql1280)
 00000000f0000000 - ffffffffffffff      00000000 <Not on bus>
Possible allocation:
< none >
```

[Send comments about this topic to Microsoft](#)

!arbiter

5/31/2017 • 1 min to read • [Edit Online](#)

The **!arbiter** extension displays the current system resource arbiters and arbitrated ranges.

```
!arbiter [Flags]
```

Parameters

Flags

Specifies which classes of arbiters are displayed. If omitted, all arbiters are displayed. These bits can be combined freely.

Bit 0 (0x1)

Display I/O arbiters.

Bit 1 (0x2)

Display memory arbiters.

Bit 2 (0x4)

Display IRQ arbiters.

Bit 3 (0x8)

Display DMA arbiters.

Bit 4 (0x10)

Display bus number arbiters.

Bit 8 (0x100)

Do not display aliases.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command.

Remarks

For each arbiter, **!arbiter** displays each allocated range of system resources, some optional flags, the PDO attached to that range (in other words, the range's owner), and the service name of this owner (if known).

The flags have the following meanings:

FLAG	MEANING
S	Range is shared
C	Range in conflict
B	Range is boot-allocated
D	Range is driver-exclusive
A	Range alias
P	Range positive decode

Here is an example:

```
kd> !arbiter 4

DEVNODE 80e203b8 (HTREE\ROOT\0)
  Interrupt Arbiter "" at 80167140
  Allocated ranges:
    0000000000000000 - 0000000000000000 B  80e1d3d8
    0000000000000001 - 0000000000000001 B  80e1d3d8
    .....
    0000000000000001a2 - 0000000000000001a2 CB  80e1d3d8
    0000000000000001a2 - 0000000000000001a2 CB  80e52538 (Serial)
    0000000000000001a3 - 0000000000000001a3     80e52778 (i8042prt)
    0000000000000001b3 - 0000000000000001b3     80e1b618 (i8042prt)
  Possible allocation:
    < none >
```

In this example, the next-to-last line shows the resource range (which consists of 0x1A3 alone), the PDO of 0x80E52778, and the service of i8042prt.sys. No flags are listed on this line.

You can now use **!devobj** with this PDO address to find the device extension and device node addresses:

```
kd> !devobj 80e52778
Device object (80e52778) is for:
  00000034 \Driver\PnpManager DriverObject 80e20610
  Current Irp 00000000 RefCount 1 Type 00000004 Flags 00001040
  DevExt 80e52830 DevObjExt 80e52838 DevNode 80e52628
  ExtensionFlags (0000000000)
  AttachedDevice (Upper) 80d78b28 \Driver\i8042prt
  Device queue is not busy.
```

[Send comments about this topic to Microsoft](#)

!late

5/31/2017 • 1 min to read • [Edit Online](#)

The **!late** extension displays the alternate page table entry (ATE) for the specified address.

```
!late Address
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Address

Specifies the ATE to display.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about page tables and page directories, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

This extension is only available on Itanium-based computers.

The status flags for the ATE are shown in the following table. The **!late** display indicates these bits with capital letters or dashes and adds additional information as well.

DISPLAY WHEN SET	DISPLAY WHEN CLEAR	MEANING
V	-	Commit.
G	-	Not accessed.
E	-	Execute.
W	R	Writeable or read-only.

DISPLAY WHEN SET	DISPLAY WHEN CLEAR	MEANING
L	-	Locked. The ATE is locked, therefore, any faults on the page that contain the ATE will be retried until the current fault is satisfied. This can happen on multi-processor systems.
Z	-	Fill zero.
N	-	No access.
C	-	Copy on Write.
I	-	PTE indirect. This ATE indirectly references another physical page. The page that contains the ATE might have two conflicting ATE attributes.
P		Reserved.

[Send comments about this topic to Microsoft](#)

!bcb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!bcb** extension displays the specified buffer control block.

```
!bcb Address
```

Parameters

Address

Specifies the address of the buffer control block.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable (see Remarks section)

Additional Information

For information about cache management, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

For information about other cache management extensions, use the [!icchelp](#) extension.

Remarks

This extension is available for Windows 2000 only. In Windows XP or later, use the [dt nt!_BCB Address](#) command to display the buffer control block directly.

[Send comments about this topic to Microsoft](#)

!blockeddrv

5/31/2017 • 1 min to read • [Edit Online](#)

The **!blockeddrv** extension displays the list of blocked drivers on the target computer.

```
!blockeddrv
```

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

Here is an example:

```
kd> !blockeddrv
Driver:      Status      GUID
afd.sys      0: {00000008-0206-0001-0000-000030C964E1}

!bpid

5/31/2017 • 2 min to read • [Edit Online](#)

The **!bpid** extension requests that a process on the target computer break into the debugger or requests that a user-mode debugger be attached to a process on the target computer.

```
!bpid [Options] PID
```

Parameters

Option

Controls the additional activities of this command.

The valid values for *Option* appear in the following table.

-a	Attaches a new user-mode debugger to the process specified by <i>PID</i> . The user-mode debugger runs on the target machine.
-s	Adds a breakpoint that occurs in the WinLogon process immediately before the break in the user-mode process specified by <i>PID</i> . This allows the user to verify the request before attempting the action.
-w	Stores the request in the memory in the target computer. The target system can then repeat the request, but this is not usually necessary.

PID

Specifies the process ID of the desired process on the target computer. If you are using this to control a user-mode debugger on the target computer, *PID* should be the process ID of the target application, not of the user-mode debugger. (Because process IDs are usually listed in decimal format, you might need to prefix this with **0n** or convert it to hexadecimal format.)

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command is supported on x86-based, x64-based, and Itanium-based target computers.

Remarks

This command is especially useful when redirecting input and output from a user-mode debugger to the kernel debugger. It causes the user-mode target application to break into the user-mode debugger, which in turn requests input from the kernel debugger. See [Controlling the User-Mode Debugger from the Kernel Debugger](#) for details.

If this command is used in another situation, the user-mode process calls **DbgBreakPoint**. This will usually break directly into the kernel debugger.

The **-s** option causes a break in WinLogon just before the break in the specified process occurs. This is useful if you want to perform debugging actions within WinLogon's process context. The **g (Go)** command can then be used to move on to the second break.

Note that there are ways in which this extension can fail to execute:

- Lack of resources. The **!bpid** extension injects a thread into the target process, so the system must have enough resources to create a thread. Using the **-a** option requires even more system resources since **!bpid -a** must run a full instance of a debugger on the target computer.
- The loader lock is already held. Both **!bpid** and **!bpid -a** require a thread to run in the target process in order to make it break into the debugger. If another thread is holding the loader lock, then the **!bpid** thread will not be able to run and a break into the debugger may not occur. Thus, if **!bpid** fails when there is enough user-mode memory available for the target process, it is possible that the loader lock is held.
- Lack of permission. The operation of the **!bpid** extension requires permission sufficient for WinLogon to create a remote thread and attach a debugger to a given process.
- No access to ntsd.exe. If ntsd.exe is not found in a commonly known path, **!bpid** will fail to set an appropriate PID. Note that ntsd.exe is not included by default with Windows Vista.

[Send comments about this topic to Microsoft](#)

!btb

5/31/2017 • 1 min to read • [Edit Online](#)

The **!btb** extension displays the Itanium-based processor, branch traces buffer (BTB) configuration and trace registers for the current processor.

```
!btb
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium-based target computer.

[Send comments about this topic to Microsoft](#)

!bth

5/31/2017 • 1 min to read • [Edit Online](#)

The **!bth** extension displays the Itanium-based branch traces history for the specified processor.

```
!bth [Processor]
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Processor

Specifies a processor. If *Processor* is omitted, then the branch trace history for all of processors is displayed.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium-based target computer.

[Send comments about this topic to Microsoft](#)

!bugdump

5/31/2017 • 1 min to read • [Edit Online](#)

The **!bugdump** extension formats and displays the information contained in the bug check callback buffers.

```
!bugdump [Component]
```

Parameters

Component

Specifies the component whose callback data is to be examined. If omitted, all bug check callback data is displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For more information, see [Reading Bug Check Callback Data](#).

Remarks

This extension can only be used after a bug check has occurred, or when you are debugging a kernel-mode crash dump file.

The *Component* parameter corresponds to the final parameter used in [KeRegisterBugCheckCallback](#).

The buffers that hold callback data are not available in a Small Memory Dump. These buffers are present in Kernel Memory Dumps and Full Memory Dumps. However, in Windows XP SP1, Windows Server 2003, and later versions of Windows, the dump file is created before the drivers' **BugCheckCallback** routines are called, and therefore these buffers will not contain the data written by these routines.

If you are performing live debugging of a crashed system, all callback data will be present.

[Send comments about this topic to Microsoft](#)

!bushnd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!bushnd** extension displays a HAL BUS_HANDLER structure.

```
!bushnd [Address]
```

Parameters

Address

Specifies the hexadecimal address of the HAL BUS_HANDLER structure. If omitted, **!bushnd** displays a list of buses and the base address of the handler.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

[Send comments about this topic to Microsoft](#)

!ca

5/31/2017 • 2 min to read • [Edit Online](#)

The **!ca** extension displays information about a control area.

```
!ca [Address | 0 | -1] [Flags]
```

Parameters

Address

Address of the control area. If you specify 0 for this parameter, information is displayed about all control areas. If you specify -1 for this parameter, information is displayed about the unused segment list.

Flags

Flags that specify which information is displayed. This parameter is a bitwise OR of one or more of the following flags.

FLAG	DESCRIPTION
0x1	Display segment information.
0x2	Display subsection information.
0x4	Display the list of mapped views. (Windows 7 and later)
0x8	Display compact (single line) output.
0x10	Display file-backed control areas.
0x20	Display control areas backed by the page file.
0x40	Display image control areas.

If none of the last three flags are specified, all three types of control area are displayed.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about control areas, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

(This book may not be available in some languages and countries.)

Remarks

To get a list of the control areas of all mapped files, use the **!memusage** extension.

Here is an example:

```
kd> !memusage
loading PFN database
loading (99% complete)
    Zeroed:    16 (    64 kb)

[Send comments about this topic to Microsoft](#)

!callback

5/31/2017 • 1 min to read • [Edit Online](#)

The **!callback** extension displays the callback data related to the trap for the specified thread.

```
!callback Address [Number]
```

Parameters

Address

Specifies the hexadecimal address of the thread. If this is -1 or omitted, the current thread is used.

Number

Specifies the number of the desired callback frame. This frame is noted in the display.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

This extension command can only be used with an x86-based target computer.

Additional Information

For information about system traps, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

If the system has not experienced a system trap, this extension will not produce useful data.

[Send comments about this topic to Microsoft](#)

!calldata

5/31/2017 • 1 min to read • [Edit Online](#)

The **!calldata** extension displays performance information in the form of procedure call statistics from the named table.

`!calldata Table`

Parameters

Table

Name of the table that collects the call data.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

[Send comments about this topic to Microsoft](#)

!can_write_kdump

5/31/2017 • 1 min to read • [Edit Online](#)

The **!can_write_kdump** extension verifies that there is enough disk space on the target computer to write a kernel dump file of the specified type.

```
!can_write_kdump [-dn] [Options]
```

Parameters

-dn

Specifies that the file system on the target computer is an NTFS file system. If this parameter is omitted, then the amount of disk free space cannot be determined, and a warning will be shown. However, the amount of space required will still be displayed.

Options

The following options are valid:

-t

Specifies that the extension should determine if there is enough space for a minidump.

-s

Specifies that the extension should determine if there is enough space for a summary kernel dump. This is the default value.

-f

Specifies that the extension should determine if there is enough space for a full kernel dump.

DLL

Windows 2000	Kext.dll
Windows XP and later	Kext.dll

Remarks

If no *Option* is specified, then the extension will determine if there is enough space for a summary kernel dump.

In the following example, the file system is not specified:

```
kd> !can_write_kdump
Checking kernel summary dump...
WARNING: Can't predict how many pages will be used, assuming worst-case.
Physical memory: 285560 KB
Page file size: 1572864 KB
NO: Page file too small
```

[Send comments about this topic to Microsoft](#)

!cbreg

5/31/2017 • 1 min to read • [Edit Online](#)

The **!cbreg** extension displays CardBus Socket registers and CardBus Exchangable Card Architecture (ExCA) registers.

```
!cbreg [%%]Address
```

Parameters

%%

Indicates that *Address* is a physical address rather than a virtual address.

Address

Specifies the address of the register to be displayed.

DLL

Windows 2000	Kext.dll Kdextx86.dll
Windows XP and later	Kext.dll

The **!cbreg** extension is only available for an x86-based target computer.

Additional Information

The **!exca** extension can be used to display PCIC ExCA registers by socket number.

[Send comments about this topic to Microsoft](#)

!cchelp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!cchelp** extension displays some brief Help text in the Debugger command window for some of the cache management extensions.

```
!cchelp
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about cache management, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

The **!cchelp** extension displays help for the **!bcb**, **!defwrites**, **!finddata**, and **!scm** cache management extensions. Other cache management extensions include **!openmaps** and **!pcm**.

[Send comments about this topic to Microsoft](#)

!chklowmem

5/31/2017 • 1 min to read • [Edit Online](#)

The **!chklowmem** extension determines whether physical memory pages below 4 GB are filled with the required fill pattern on a computer that was booted with the **/pae** and **/nolowmem** options.

```
!chklowmem
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

This extension is useful when you are verifying that kernel-mode drivers operate properly with physical memory above the 4 GB boundary. Typically, drivers fail by truncating a physical address to 32 bits and then in writing below the 4 GB boundary. The **!chklowmem** extension will detect any writes below the 4 GB boundary.

[Send comments about this topic to Microsoft](#)

!cmreslist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!cmreslist** extension displays the CM_RESOURCE_LIST structure for the specified device object.

```
!cmreslist Address
```

Parameters

Address

Specifies the hexadecimal address of the CM_RESOURCE_LIST structure.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about the CM_RESOURCE_LIST structure, see the Windows Driver Kit (WDK) documentation.

[Send comments about this topic to Microsoft](#)

!cpuinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!cpuinfo** extension displays detailed information about the target computer's CPU.

Syntax

```
!cpuinfo [Processor]
```

Parameters

Processor

Specifies the processor to be displayed. If this is omitted, all processors are displayed.

DLL

Kdexts.dll

Additional Information

For more information about debugging multiprocessor computers, see [Multiprocessor Syntax](#).

Remarks

The **!cpuinfo** extension command can be used when performing [local kernel debugging](#).

Here is an example generated by an x86-based processor:

```
kd> !cpuinfo
CP F/M/S Manufacturer  MHz Update Signature Features
 0 6,1,9 GenuineIntel 198 000000d200000000 000000ff
```

Here is an example generated by an Itanium-based processor:

```
kd> !cpuinfo
CP M/R/F/A Manufacturer      SerialNumber      Features      Speed
 0 2,1,31,0 GenuineIntel    0000000000000000 0000000000000001 1300 Mhz
 1 2,1,31,0 GenuineIntel    0000000000000000 0000000000000001 1300 Mhz
```

The **CP** column indicates the processor number. The **Manufacturer** column specifies the processor manufacturer.

The **MHz** or **Speed** column specifies the speed, in MHz, of the processor, if it is available.

For an x86-based processor or an x64-based processor, the **F** column displays the processor family number, the **M** column displays the processor model number, and the **S** column displays the stepping size.

For an Itanium-based processor, the **M** column displays the processor model number, the **R** column displays the processor revision number, the **F** column displays the processor family number, and the **A** column displays the architecture revision number.

Other columns will also appear, depending on your machine's specific architecture.

For details on how to interpret specific values for each entry, as well as any additional columns, consult the processor manual.

[Send comments about this topic to Microsoft](#)

!db, !dc, !dd, !dp, !dq, !du, !dw

5/31/2017 • 3 min to read • [Edit Online](#)

The **!db**, **!dc**, **!dd**, **!dp**, **!dq**, **!du**, and **!dw** extensions display data at the specified physical address on the target computer.

These extension commands should not be confused with the **d* (Display Memory)** command, or with the **!ntsdexts.dp** extension command.

```
!db [Caching] [-m] [PhysicalAddress] [L Size]
!dc [Caching] [-m] [PhysicalAddress] [L Size]
!dd [Caching] [-m] [PhysicalAddress] [L Size]
!dp [Caching] [-m] [PhysicalAddress] [L Size]
!dq [Caching] [-m] [PhysicalAddress] [L Size]
!du [Caching] [-m] [PhysicalAddress] [L Size]
!dw [Caching] [-m] [PhysicalAddress] [L Size]
```

Parameters

Caching

Can be any one of the following values. The *Caching* value must be surrounded by square brackets:

[c]

Causes this extension to read from cached memory.

[uc]

Causes this extension to read from uncached memory.

[wc]

Causes this extension to read from write-combined memory.

-m

Causes memory to be read one unit at a time. For example, **!db -m** reads memory in 8-bit chunks and **!dw -m** reads memory in 16-bit chunks. If your hardware does not support 32-bit physical memory reads, it may be necessary to use the **-m** option. This option does not affect the length or appearance of the display -- it only affects how the memory is accessed.

PhysicalAddress

Specifies the first physical address to be displayed, in hexadecimal format. If this is omitted the first time this command is used, the address defaults to zero. If this is omitted on a subsequent use, the display will begin where the last display ended.

L ** Size**

Specifies the number of chunks of memory to display. The size of a chunk is determined by the precise extension used.

DLL

Windows 2000	Kext.dll Kdextx86.dll
Windows XP and later	Kext.dll

Additional Information

To write to physical memory, use the **!e*** extensions. For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

Remarks

These extensions each display physical memory, but their display formats and default length differ:

- The **!db** extension displays hexadecimal bytes and their ASCII character equivalents. The default length is 128 bytes.
- The **!dc** extension displays DWORD values and their ASCII character equivalents. The default length is 32 DWORDs (128 total bytes).
- The **!dd** extension displays DWORD values. The default length is 32 DWORDs (128 total bytes).
- The **!dp** extension displays ULONG_PTR values. These are either 32-bit or 64-bit words, depending on the instruction size. The default length is 128 total bytes.
- The **!dq** extension displays ULONG64_PTR values. These are 32-bit words. The default length is 128 total bytes.
- The **!du** extension displays UNICODE characters. The default length is 16 characters (32 total bytes), or until a NULL character is encountered.
- The **!dw** extension displays WORD values. The default length is 64 DWORDs (128 total bytes).

Consequently, using two of these extensions that are distinct with the same value of *Size* will most likely result in a difference in the total amount of memory displayed. For example, using the command **!db L 32** results in 32 bytes being displayed (as hexadecimal bytes), whereas the command **!dd L 32** results in 128 bytes being displayed (as DWORD values).

Here is an example in which the caching attribute flag is needed:

```
kd> !dc e9000
physical memory read at e9000 failed
If you know the caching attributes used for the memory,
try specifying [c], [uc] or [wc], as in !dd [c] <params>.
WARNING: Incorrect use of these flags will cause unpredictable
processor corruption. This may immediately (or at any time in
the future until reboot) result in a system hang, incorrect data
being displayed or other strange crashes and corruption.

kd> !dc [c] e9000
#  e9000 000ea002 000ea002 000ea002 000ea002 .....
#  e9010 000ea002 000ea002 000ea002 000ea002 .....
```

[Send comments about this topic to Microsoft](#)

!dbgprint

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dbgprint** extension displays a string that was previously sent to the **DbgPrint** buffer.

```
!dbgprint
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about **DbgPrint**, **KdPrint**, **DbgPrintEx**, and **KdPrintEx**, see [Sending Output to the Debugger](#).

Remarks

The kernel-mode routines **DbgPrint**, **KdPrint**, **DbgPrintEx**, and **KdPrintEx** send a formatted string to a buffer on the target computer. The string is automatically displayed in the Debugger Command window on the host computer unless such printing has been disabled.

Generally, messages sent to this buffer are displayed automatically in the Debugger Command window. However, this display can be disabled through the Global Flags (gflags.exe) utility. Moreover, this display does not automatically appear during local kernel debugging. For more information, see [The DbgPrint Buffer](#).

The **!dbgprint** extension causes the contents of this buffer to be displayed (regardless of whether automatic printing has been disabled). It will not show messages that have been filtered out based on their component and importance level. (For details on this filtering, see [Reading and Filtering Debugging Messages](#).)

[Send comments about this topic to Microsoft](#)

!dblink

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dblink** extension displays a linked list in the backward direction.

```
!dblink Address [Count] [Bias]
```

Parameters

Address

Specifies the address of a LIST_ENTRY structure. The display will begin with this node.

Count

Specifies the maximum number of list entries to display. If this is omitted, the default is 32.

Bias

Specifies a mask of bits to ignore in each pointer. Each **Blink** address is ANDed with (NOT *Bias*) before following it to the next location. The default is zero (in other words, do not ignore any bits).

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

The **!dblink** extension traverses the **Blink** fields of the LIST_ENTRY structure and displays up to four ULONGs at each address. To go in the other direction, use [!dflink](#).

The [dl \(Display Linked List\)](#) command is more versatile than **!dblink** and [!dflink](#).

[Send comments about this topic to Microsoft](#)

!dcr

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dcr** extension displays the default control register (DCR) at the specified address.

```
!dcr Expression [DisplayLevel]
```

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Expression

Specifies the hexadecimal address of the DCR to display. The expression **@dcr** can also be used for this parameter. In that case, information about the current processor DCR is displayed.

DisplayLevel

Can be any one of the following options:

0

Causes only the values of each DCR field to be displayed. This is the default value.

1

Causes the display to include more in-depth information about each of the DCR fields that is not reserved or ignored.

2

Causes the display to include more in-depth information about all of the DCR fields, including those that are ignored or reserved.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium-based target computer.

Remarks

The DCR specifies default parameters for the processor status register values on interruption. The DCR also specifies some additional global controls, as well as whether or not speculative load faults can be deferred.

Here are a couple of examples:

```
kd> !dcr @dcr
dcr:pp be lc dm dp dk dx dr da dd
1 0 1 1 1 1 1 1 1 1

kd> !dcr 2

pp : 1 : Privileged Performance Monitor Default
be : 0 : Big-Endian Default
lc : 1 : IA-32 Lock check Enable
rv : 0 : reserved1
dm : 1 : Defer TLB Miss faults only
dp : 1 : Defer Page Not Present faults only
dk : 1 : Defer Key Miss faults only
dx : 1 : Defer Key Permission faults only
dr : 1 : Defer Access Rights faults only
da : 1 : Defer Access Bit faults only
dd : 0 : Defer Debug faults only
rv : 0 : reserved2
```

[Send comments about this topic to Microsoft](#)

!dcs

5/26/2017 • 1 min to read • [Edit Online](#)

The **!dcs** extension is obsolete. To display the PCI configuration space, use **!pci 100***Bus Device Function*.

[Send comments about this topic to Microsoft](#)

!deadlock

5/31/2017 • 2 min to read • [Edit Online](#)

The **!deadlock** extension displays information about deadlocks collected by the **Deadlock Detection** option of Driver Verifier.

```
!deadlock
!deadlock 1
```

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about Driver Verifier, see the Windows Driver Kit (WDK) documentation.

Remarks

This extension will only provide useful information if Driver Verifier's **Deadlock Detection** option has detected a lock hierarchy violation and issued **bug check 0xC4** (DRIVER_VERIFIER_DETECTED_VIOLATION).

Without any arguments, the **!deadlock** extension causes the basic lock hierarchy topology to be displayed. If the problem is not a simple cyclical deadlock, this command will describe the situation that has occurred.

The **!deadlock 1** extension causes stack traces to be displayed. The stacks displayed will be the ones active at the time the locks were acquired.

Here is an example:

```
0:kd> !deadlock

Deadlock detected (2 resources in 2 threads):

Thread 0: A B
Thread 1: B A

Where:
Thread 0 = 8d3ba030
Thread 1 = 8d15c030
Lock A = bba2af30 Type 'Spinlock'
Lock B = dummy!GlobalLock Type 'Spinlock'
```

This tells you which threads and which locks are involved. However, it is intended to be a summary and may not be enough information to adequately debug the situation.

Use **!deadlock 1** to print out the contents of the call stacks at the time that each lock participating in the deadlock was acquired. Because these are run-time stack traces, they will be more complete if a checked build is being used. On a free build, they may be truncated after as little as one line.

```
0:kd> !deadlock 1

Deadlock detected (2 resources in 2 threads):

Thread 0 (8D14F750) took locks in the following order:

Lock A -- b7906f30 (Spinlock)
Stack:  dummy!DummyActivateVcComplete+0x63
        dummy!dummyOpenVcChannels+0x2E1
        dummy!DummyAllocateRecvBufferComplete+0x436
        dummy!DummyAllocateComplete+0x55
        NDIS!ndisMQueuedAllocateSharedHandler+0xC9
        NDIS!ndisWorkerThread+0xEE

Lock B -- dummy!GlobalLock (Spinlock)
Stack:  dummy!dummyQueueRecvBuffers+0x2D
        dummy!DummyActivateVcComplete+0x90
        dummy!dummyOpenVcChannels+0x2E1
        dummy!DummyAllocateRecvBufferComplete+0x436
        dummy!DummyAllocateComplete+0x55

Thread 1 (8D903030) took locks in the following order:

Lock B -- dummy!GlobalLock (Spinlock)
Stack:  dummy!dummyRxInterruptOnCompletion+0x25D
        dummy!DummyHandleInterrupt+0x32F
        NDIS!ndisMDpcX+0x3C
        ntkrnlp!KiRetireDpcList+0x5D

Lock A -- b7906f30 (Spinlock)
Stack:  << Current stack >>
```

With this information, you have almost everything you need, except the current stack:

```
0: kd> k
ChildEBP RetAddr
f78aae6c 80664c58 ntkrnlp!DbgBreakPoint
f78aae74 8066523f ntkrnlp!ViDeadlockReportIssue+0x2f
f78aae9c 806665df ntkrnlp!ViDeadlockAnalyze+0x253
f78aaee8 8065d944 ntkrnlp!VfDeadlockAcquireResource+0x20b
f78aaaf08 bfd6df46 ntkrnlp!VerifierKeAcquireSpinLockAtDpcLevel+0x44
f78aaafa4 b1bf2d2d dummy!dummyRxInterruptOnCompletion+0x2b5
f78aafc4 bfde9d8c dummy!DummyHandleInterrupt+0x32f
f78aafd8 804b393b NDIS!ndisMDpcX+0x3c
f78aaff4 804b922b ntkrnlp!KiRetireDpcList+0x5d
```

From this you can see which locks were involved and where they were acquired. This should be enough information for you to debug the deadlock. If the source code is available, you can use the debugger to see exactly where the problem occurred:

```
0: kd> .lines
Line number information will be loaded

0: kd> u dummy!DummyActivateVcComplete+0x63 11
dummy!DummyActivateVcComplete+63 [d:\nt\drivers\dummy\vc.c @ 2711]:
b1bfe6c9 837d0c00      cmp     dword ptr [ebp+0xc],0x0

0: kd> u dummy!dummyQueueRecvBuffers+0x2D 11
dummy!dummyQueueRecvBuffers+2d [d:\nt\drivers\dummy\receive.c @ 2894]:
b1bf4e39 807d0c01      cmp     byte ptr [ebp+0xc],0x1

0: kd> u dummy!dummyRxInterruptOnCompletion+0x25D 11
dummy!dummyRxInterruptOnCompletion+25d [d:\nt\drivers\dummy\receive.c @ 1424]:
b1bf5d05 85f6          test    esi,esi

0: kd> u dummy!dummyRxInterruptOnCompletion+0x2b5 11
dummy!dummyRxInterruptOnCompletion+2b5 [d:\nt\drivers\dummy\receive.c @ 1441]:
b1bf5d5d 8b4648         mov     eax,[esi+0x48]
```

Now you know the name of the source file and the line number where the acquisition took place. In this case, the source files will show that the threads behaved as follows:

- Thread 1: **DummyActivateVcComplete** took the **dummy** miniport lock. It then called **dummyQueueRecvBuffers**, which took the **dummy** global lock.
- Thread 2: **dummyRxInterruptOnCompletion** took the global lock. Then, a few lines later, it took the miniport lock.

At this point, the deadlock becomes entirely clear.

[Send comments about this topic to Microsoft](#)

!defwrites

5/31/2017 • 1 min to read • [Edit Online](#)

The **!defwrites** extension displays the values of the kernel variables used by the cache manager.

```
!defwrites
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about write throttling, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

For information about other cache management extensions, use the **!icchelp** extension.

Remarks

When the number of deferred writes ("dirty pages") becomes too large, page writing will be throttled. This extension allows you to see whether your system has reached this point.

Here is an example:

```
kd> !defwrites
*** Cache Write Throttle Analysis ***

CcTotalDirtyPages:          0 (      0 Kb)
CcDirtyPageThreshold:       1538 (  6152 Kb)
MmAvailablePages:           2598 ( 10392 Kb)
MmThrottleTop:              250 ( 1000 Kb)
MmThrottleBottom:            30 ( 120 Kb)
MmModifiedPageListHead.Total: 699 ( 2796 Kb)

Write throttles not engaged
```

In this case, there are no dirty pages. If **CcTotalDirtyPages** reaches 1538 (the value of **CcDirtyPageThreshold**), writing will be delayed until the number of dirty pages is reduced.

[Send comments about this topic to Microsoft](#)

!devext

5/31/2017 • 1 min to read • [Edit Online](#)

The **!devext** extension displays bus-specific device extension information for devices on a variety of buses.

```
!devext Address TypeCode
```

Parameters

Address

Specifies the hexadecimal address of the device extension to be displayed.

TypeCode

Specifies the type of object that owns the device extension to be displayed. Type codes are not case-sensitive. Valid type codes are:

TYPECODE	OBJECT
PCI	(Windows 2000 only) PCI device extension
ISAPNP	ISA PnP device extension
PCMCIA	PCMCIA device extension
HID	HID device extension
USBD	(Windows 2000 only) USB bus driver extension
UHCD	(Windows 2000 only) UHCD host controller extension
OpenHCI	(Windows 2000 only) Open HCI host controller extension
USBHUB	(Windows 2000 only) USB hub extension
MF	(Windows 2000 only) MF device extension

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For more information about device extensions, see the Windows Driver Kit (WDK) documentation.

Remarks

The **!usbhub**, **!hidfdo**, and **!hidpdo** extensions are obsolete; their functionality has been integrated into **!devext**.

For those object types that are no longer supported by **!devext**, use the [dt \(Display Type\)](#) debugger command.

Here is an example for an ISA PnP device extension:

```
kd> !devext e0000165fff32190 ISAPNP
ISA PnP FDO @ 0x00000000, DevExt @ 0xe0000165fff32190, Bus # 196639
Flags (0x854e2530)  DF_ACTIVATED, DF_QUERY_STOPPED,
                     DF_STOPPED, DF_RESTARTED_NOMOVE,
                     DF_BUS
                     Unknown flags 0x054e2000

NumberCSNs          - -536870912
ReadDataPort        - 0x0000000d (mapped)
AddressPort         - 0x00000000 (not mapped)
CommandPort         - 0x00000000 (not mapped)
DeviceList          - 0xe000000085007b50
CardList            - 0x00000000
PhysicalBusDevice  - 0x00000000
AttachedDevice      - 0x00000000
SystemPowerState   - Unspecified
DevicePowerState   - Unspecified
```

Here is an example for a PCI device:

```
kd> !devext e0000000858c31b0 PCI
PDO Extension, Bus 0x0, Device 0, Function 0.
DevObj 0xe0000000858c3060 PCI Parent Bus FDO DevExt 0xe0000000858c4960
Device State = PciNotStarted
Vendor ID 8086 (INTEL) Device ID 123D
Class Base/Sub 08/00 (Base System Device/Interrupt Controller)
Programming Interface: 20, Revision: 01, IntPin: 00, Line Raw/Adj 00/00
Enables ((cmd & 7) = 106): BM Capabilities Pointer = <none>
CurrentState:      System Working, Device D0
WakeLevel:         System Unspecified, Device Unspecified
Requirements: <none>
```

[Send comments about this topic to Microsoft](#)

!devhandles

5/31/2017 • 1 min to read • [Edit Online](#)

The **!devhandles** extension displays the open handles for the specified device.

```
!devhandles Address
```

Parameters

Address

Specifies the address of the device for which to display the open handles.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

To display complete handle information, this extension requires private symbols.

The address of a device object can be obtained using the **!drvobj** or **!devnode** extensions.

Here is a truncated example:

```
1kd> !devhandles 0x841153d8

Checking handle table for process 0x840d3940
Handle table at 95fea000 with 578 Entries in use

Checking handle table for process 0x86951d90
Handle table at 8a8ef000 with 28 Entries in use

...
Checking handle table for process 0x87e63650
Handle table at 947bc000 with 308 Entries in use

Checking handle table for process 0x87e6f4f0
00000000: Unable to read handle table
```

[Send comments about this topic to Microsoft](#)

!devnode

5/31/2017 • 1 min to read • [Edit Online](#)

The **!devnode** extension displays information about a node in the device tree.

```
!devnode Address [Flags] [Service]
!devnode 1
!devnode 2
```

Parameters

Address

Specifies the hexadecimal address of the device extension whose node is to be displayed. If this is zero, the root of the main device tree is displayed.

Flags

Specifies the level of output to be displayed. This can be any combination of the following bits:

Bit 0 (0x1)

Causes the display to include all children of the device node.

Bit 1 (0x2)

Causes the display to include resources used (CM_RESOURCE_LIST). These include the boot configuration reported by IRP_MN_QUERY_RESOURCES, as well as the resources allocated to the device in the *AllocatedResources* parameter of IRP_MN_START_DEVICE.

Bit 2 (0x4)

Causes the display to include resources required (IO_RESOURCE_REQUIREMENTS_LIST) as reported by IRP_MN_FILTER_RESOURCE_REQUIREMENTS.

Bit 3 (0x8)

Causes the display to include a list of translated resources as allocated to the device in the *AllocatedResourcesTranslated* parameter of IRP_MN_START_DEVICE.

Bit 4 (0x10)

Specifies that only device nodes that are not started should be displayed.

Bit 5 (0x20)

Specifies that only device nodes with problems should be displayed. (These are nodes that contain the flag bits DNF_HAS_PROBLEM or DNF_HAS_PRIVATE_PROBLEM.)

Service

Specifies the name of a service. If this is included, only those device nodes driven by this service will be displayed. (If *Flags* includes bit 0x1, device nodes driven by this service and all their children will be displayed.)

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about device trees, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The **!devnode 1** command lists all pending removals of device objects.

The **!devnode 2** command lists all pending ejects of device objects.

You can use **!devnode 0 1** to see the entire device tree.

[Send comments about this topic to Microsoft](#)

!devobj

5/31/2017 • 1 min to read • [Edit Online](#)

The **!devobj** extension displays detailed information about a DEVICE_OBJECT structure.

```
!devobj DeviceObject
```

Parameters

DeviceObject

Specifies the device object. This can be the hexadecimal address of this structure or the name of the device.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for examples and applications of this extension command. For information about device objects, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

If *DeviceObject* specifies the name of the device but supplies no prefix, the prefix "\Device\" is assumed. Note that this command will check to see if *DeviceObject* is a valid address or device name before using the expression evaluator.

The information displayed includes the device name of the object, information about the device's current IRP, and a list of addresses of any pending IRPs in the device's queue. It also includes information about device objects layered on top of this object (listed as "AttachedDevice") and those layered under this object (listed as "AttachedTo").

The address of a device object can be obtained using the [!drvobj](#) or [!devnode](#) extensions.

Here is one example:

```
kd> !devnode
Dumping IopRootDeviceNode (= 0x80e203b8)
DevNode 0x80e203b8 for PDO 0x80e204f8
  Parent 0000000000  Sibling 0000000000  Child 0x80e56dc8
  InstancePath is "HTREE\ROOT\0"
  State = DeviceNodeStarted (0x308)
  Previous State = DeviceNodeEnumerateCompletion (0x30d)
  StateHistory[04] = DeviceNodeEnumerateCompletion (0x30d)
  StateHistory[03] = DeviceNodeStarted (0x308)
  StateHistory[02] = DeviceNodeEnumerateCompletion (0x30d)
  StateHistory[01] = DeviceNodeStarted (0x308)
  StateHistory[00] = DeviceNodeUninitialized (0x301)
  StateHistory[19] = Unknown State (0x0)
  .....
  StateHistory[05] = Unknown State (0x0)
  Flags (0x00000131)  DNF_MADEUP, DNF_ENUMERATED,
                      DNF_IDS_QUERIED, DNF_NO_RESOURCE_REQUIRED
  DisableableDepends = 11 (from children)

kd> !devobj 80e204f8
Device object (80e204f8) is for:
  \Driver\NpManager DriverObject 80e20610
  Current Irp 00000000 RefCount 0 Type 00000004 Flags 00001000
  DevExt 80e205b0 DevObjExt 80e205b8 DevNode 80e203b8
  ExtensionFlags (0000000000)
  Device queue is not busy.
```

[Send comments about this topic to Microsoft](#)

!devstack

5/31/2017 • 1 min to read • [Edit Online](#)

The **!devstack** extension displays a formatted view of the device stack associated with a device object.

```
!devstack DeviceObject
```

Parameters

DeviceObject

Specifies the device object. This can be the hexadecimal address of the DEVICE_OBJECT structure or the name of the device.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about device stacks, see the Windows Driver Kit (WDK) documentation.

Remarks

If *DeviceObject* specifies the name of the device but supplies no prefix, the prefix "\Device\" is assumed. Note that this command will check to see if *DeviceObject* is a valid address or device name before using the expression evaluator.

Here is an example:

```
kd> !devstack e000000085007b50
!DevObj  !DrvObj          !DevExt  ObjectName
e0000165ffff32040  \Driver\kmixer      e0000165ffff32190
> e000000085007b50  \Driver\swenum      e000000085007ca0  KSENUM#00000005
!DevNode e0000165ffff2e010 :
  DeviceInst is "SW\{b7eafdc0-a680-11d0-96d8-00aa0051e51d}\{9B365890-165F-11D0-A195-0020AFD156E4}"
  ServiceName is "kmixer"
```

[Send comments about this topic to Microsoft](#)

!dflink

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dflink** extension displays a linked list in the forward direction.

```
!dflink Address [Count] [Bias]
```

Parameters

Address

Specifies the address of a LIST_ENTRY structure. The display will begin with this node.

Count

Specifies the maximum number of list entries to display. If this is omitted, the default is 32.

Bias

Specifies a mask of bits to ignore in each pointer. Each **Flink** address is ANDed with (NOT *Bias*) before following it to the next location. The default is zero (in other words, do not ignore any bits).

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

The **!dflink** extension traverses the **Flink** fields of the LIST_ENTRY structure and displays up to four ULONGs at each address. To go in the other direction, use [!dblink](#).

The [dl \(Display Linked List\)](#) command is more versatile than [!dblink](#) and [!dflink](#).

[Send comments about this topic to Microsoft](#)

!diskspace

5/31/2017 • 1 min to read • [Edit Online](#)

The **!diskspace** extension displays the amount of free space on a hard disk of the target computer.

```
!diskspace Drive[:]
```

Parameters

Drive

Specifies the drive letter of the disk. The colon (:) after *Drive* is optional.

DLL

Windows 2000	Kext.dll
Windows XP and later	Kext.dll

Remarks

Here is an example:

```
kd> !diskspace c:  
Checking Free Space for c: .....,  
Cluster Size 0 KB  
Total Clusters 4192901 KB  
Free Clusters 1350795 KB  
Total Space 1 GB (2096450 KB)  
Free Space 659.567871 MB (675397 KB)  
  
kd> !diskspace f:  
Checking Free Space for f:  
f: is a CDROM drive. This function is not supported!
```

[Send comments about this topic to Microsoft](#)

!dma

5/31/2017 • 4 min to read • [Edit Online](#)

The **!dma** extension displays information about the Direct Memory Access (DMA) subsystem, and the **DMA Verifier** option of Driver Verifier.

```
!dma
!dma Adapter [Flags]
```

Parameters

Adapter

Specifies the hexadecimal address of the DMA adapter to be displayed. If this is zero, all DMA adapters will be displayed.

Flags

Specifies the information to include in the display. This can be any combination of the following bits. The default is 0x1.

Bit 0 (0x1)

Causes the display to include generic adapter information.

Bit 1 (0x2)

Causes the display to include map register information. (Only when DMA Verification is active.)

Bit 2 (0x4)

Causes the display to include common buffer information. (Only when DMA Verification is active.)

Bit 3 (0x8)

Causes the display to include scatter/gather list information. (Only when DMA Verification is active.)

Bit 4 (0x10)

Causes the display to include the device description for the hardware device. (Only when DMA Verification is active.)

Bit 5 (0x20)

Causes the display to include Wait context block information.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about Driver Verifier, see the Windows Driver Kit (WDK) documentation. For information about DMA, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Invalid arguments (for example, **!dma 1**) generate a brief help text.

When the **!dma** extension is used with no parameters, it displays a concise list of all DMA adapters and their addresses. This can be used to obtain the address of an adapter for use in the longer versions of this command.

Here is an example of how this extension can be used when the Driver Verifier's **DMA Verification** option is active:

```
0:kd> !dma

Dumping all DMA adapters...

Adapter: 82faebd0    Owner: SCSIPORT!ScsiPortGetUncachedExtension
Adapter: 82f88930    Owner: SCSIPORT!ScsiPortGetUncachedExtension
Adapter: 82f06cd0    Owner: NDIS!NdisAllocateMapRegisters
Master adapter: 80076800
```

From this output, you can see that there are three DMA adapters in the system. SCSIPORT owns two and NDIS owns the third. To examine the NDIS adapter in detail, use the **!dma** extension with its address:

```
0:kd> !dma 82f06cd0

Adapter: 82f06cd0    Owner: NDIS!NdisAllocateMapRegisters (0x9fe24351)
MasterAdapter: 00000000
    Adapter base Va    00000000
    Map register base: 00000000
WCB:           82f2b604
    Map registers: 00000000 mapped, 00000000 allocated, 00000002 max

Dma verifier additional information:
DeviceObject: 82f98690
Map registers: 00000840 allocated, 00000000 freed
Scatter-gather lists: 00000000 allocated, 00000000 freed
Common buffers: 00000004 allocated, 00000000 freed
Adapter channels: 00000420 allocated, 00000420 freed
Bytes mapped since last flush: 000000f2
```

The first block of data is specific information that a HAL developer can use to debug the problem. For your purposes, the data below "Dma verifier additional information" is what is interesting. In this example, you see that NDIS has allocated 0x840 map registers. This is a huge number, especially because NDIS had indicated that it planned to use a maximum of two map registers. This adapter apparently does not use scatter/gather lists and has put away all its adapter channels. Look at the map registers in more detail:

```

0:kd> !dma 82f06cd0 2
Adapter: 82f06cd0      Owner: NDIS!NdisAllocateMapRegisters
...
Map register file 82f06c58 (0/2 mapped)

Double buffer mdl: 82f1b678
Map registers:
82f06250: 00bc bytes mapped to f83c003c
82f0625c: Not mapped

Map register file 82fa5ad8 (1/2 mapped)
Double buffer mdl: 82f1b048
Map registers:
82fa5b00: 0036 bytes mapped to 82d17102
82fa5b0c: Not mapped
...

```

In this example, you see that certain map registers have been mapped. Each *map register file* is an allocation of map registers by the driver. In other words, it represents a single call to **AllocateAdapterChannel**. NDIS collects a large number of these map register files, while some drivers create them one at a time and dispose of them when they are finished.

The map register files are also the addresses that are returned to the device under the name "MapRegisterBase". Note that DMA verifier only hooks the first 64 map registers for each driver. The rest are ignored for reasons of space (each map register represents three physical pages).

In this example, two map register files are in use. This means that the driver has mapped a buffer so it is visible to the hardware. In the first case, 0xBC bytes are mapped to the system virtual address 0xF83C003C.

An examination of the common buffers reveals:

```

0:kd> !dma 82f06cd0 4
Adapter: 82f06cd0      Owner: NDIS!NdisAllocateMapRegisters
...
Common buffer allocated by NDIS!NdisAllocateSharedMemory:
Length:          1000
Virtual address: 82e77000
Physical address: 2a77000

Common buffer allocated by NDIS!NdisAllocateSharedMemory:
Length:          12010
Virtual address: 82e817f8
Physical address: 2a817f8

Common buffer allocated by NDIS!NdisAllocateSharedMemory:
Length:          4300
Virtual address: 82e95680
Physical address: 2a95680

Common buffer allocated by NDIS!NdisAllocateSharedMemory:
Length:          4800
Virtual address: 82e9d400
Physical address: 2a9d400

```

This is fairly straightforward; there are four common buffers of varying lengths. The physical and virtual addresses are all given.

[Send comments about this topic to Microsoft](#)

!dpa

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dpa** extension displays pool allocation information.

```
!dpa Options  
!dpa -?
```

Parameters

Options

Must be exactly one of the following options:

-c

Displays current pool allocation statistics.

-v

Displays all current pool allocations.

-vs

Causes the display to include stack traces.

-f

Displays failed pool allocations.

-r

Displays free pool allocations.

-p ** Ptr**

Displays all pool allocations that contain the pointer *Ptr*.

-?

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

Pool instrumentation must be enabled in Win32k.sys in order for this extension to work.

[Send comments about this topic to Microsoft](#)

!dpcs

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dpcs** extension displays the deferred procedure call (DPC) queues for a specified processor.

```
!dpcs [Processor]
```

Parameters

Processor

Specifies a processor. If *Processor* is omitted, then the DPC queues for all processors are displayed.

DLL

Windows 2000	Unavailable
Windows XP	Unavailable
Windows Server 2003 and later	Kdexts.dll

Additional Information

For information about DPCs, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

[Send comments about this topic to Microsoft](#)

!driveinfo

5/31/2017 • 1 min to read • [Edit Online](#)

The **!driveinfo** extension displays volume information for the specified drive.

```
!driveinfo Drive[:]
!driveinfo
```

Parameters

Drive

Specifies a drive. The colon at the end of the drive name is optional.

No parameters

Displays some brief Help text for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

The drive information displayed by this extension is obtained by querying the underlying file system; for example:

```
kd> !driveinfo c:
Drive c:, DriveObject e136cd88
  Directory Object: e1001408  Name: C:
    Target String is '\Device\HarddiskVolume1'
    Drive Letter Index is 3 (C:)
  Volume DevObj: 82254a68
    Vpb: 822549e0  DeviceObject: 82270718
  FileSystem: \FileSystem\Ntfs
    Volume has 0x229236 (free) / 0x2ee1a7 (total) clusters of size 0x1000
    8850.21 of 12001.7 MB free
```

[Send comments about this topic to Microsoft](#)

!drivers

5/31/2017 • 3 min to read • [Edit Online](#)

In Windows XP and later versions of Windows, the **!drivers** extension is obsolete. To display information about loaded drivers and other modules, use the **!lm** command. The command **!lm tn** displays information in a format very similar to the old **!drivers** extension. However, this command will not display the memory usage of the drivers as the **!drivers** extension did. It will only display the drivers' start and end addresses, image names, and timestamps. The **!lvm** and **!memusage** extensions can be used to display memory usage statistics.

```
!drivers [Flags]
```

Parameters

Flags

Can be any combination of the following values. (The default is 0x0.)

Bit 0 (0x1)

Causes the display to include information about resident and standby memory.

Bit 1 (0x2)

If this bit is set and bit 2 (0x4) is not set, the display will include information about resident, standby, and locked memory, as well as the loader entry address. If bit 2 is set, this causes the display to be a much longer and more detailed list of the driver image. Information about the headers is included, as is section information.

Bit 2 (0x4)

Causes the display to be a much longer and more detailed list of the driver image. Information about each section is included. If bit 1 (0x2) is set, this will also include header information.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Unavailable

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about drivers and their memory use, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

An explanation of this command's display is given in the following table:

COLUMN	MEANING
--------	---------

COLUMN	MEANING
Base	The starting address of the device driver code, in hexadecimal. When the memory address used by the code that causes a stop falls between the base address for a driver and the base address for the next driver in the list, that driver is frequently the cause of the fault. For instance, the base for Ncrc810.sys is 0x80654000. Any address between that and 0x8065a000 belongs to this driver.
Code Size	The size, in kilobytes, of the driver code, in both hexadecimal and decimal.
Data Size	The amount of space, in kilobytes, allocated to the driver for data, in both hexadecimal and decimal.
Locked	(Only when Flag 0x2 is used) The amount of memory locked by the driver.
Resident	(Only when Flag 0x1 or 0x2 is used) The amount of the driver's memory that actually resides in physical memory.
Standby	(Only when Flag 0x1 or 0x2 is used) The amount of the driver's memory that is on standby.
Loader Entry	(Only when Flag 0x2 is used) The loader entry address.
Driver Name	The driver file name.
Creation Time	The link date of the driver. Do not confuse this with the file date of the driver, which can be set by external tools. The link date is set by the compiler when a driver or executable file is compiled. It should be close to the file date, but it is not always the same.

The following is a truncated example of this command:

```
kd> !drivers
Loaded System Driver Summary
Base      Code Size      Data Size      Driver Name  Creation Time
80080000  f76c0 (989 kb) 1f100 (124 kb) ntoskrnl.exe  Fri May 26 15:13:00
80400000  d980  ( 54 kb) 4040  ( 16 kb) hal.dll      Tue May 16 16:50:34
80654000  3f00  ( 15 kb) 1060  (  4 kb) ncrc810.sys  Fri May 05 20:07:04
8065a000  a460  ( 41 kb) 1e80  (   7 kb) SCSIPORT.SYS Fri May 05 20:08:05
```

[Send comments about this topic to Microsoft](#)

!drvobj

5/31/2017 • 1 min to read • [Edit Online](#)

The **!drvobj** extension displays detailed information about a DRIVER_OBJECT.

```
!drvobj DriverObject [Flags]
```

Parameters

DriverObject

Specifies the driver object. This can be the hexadecimal address of the DRIVER_OBJECT structure or the name of the driver.

Flags

Can be any combination of the following bits. (The default is 0x01.)

Bit 0 (0x1)

Causes the display to include device objects owned by the driver.

Bit 1 (0x2)

Causes the display to include entry points for the driver's dispatch routines.

Bit 2 (0x4)

Lists with detailed information the device objects owned by the driver (requires bit 0 (0x1)).

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for examples and applications of this extension command. For information about driver objects, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

If *DriverObject* specifies the name of the device but supplies no prefix, the prefix "\Driver\" is assumed. Note that this command will check to see if *DriverObject* is a valid address or device name before using the expression evaluator.

If *DriverObject* is an address, it must be the address of the DRIVER_OBJECT structure. This can be obtained by examining the arguments passed to the driver's **DriverEntry** routine.

This extension command will display a list of all device objects created by a specified driver. It will also display all fast I/O routines registered with this driver object.

The following is an example for the Symbios Logic 810 SCSI miniport driver:

```
kd> bp DriverEntry          //  breakpoint at DriverEntry

kd> g
symc810!DriverEntry+0x40:
80006a20: b07e0050 stl      t2,50(sp)

kd> r a0  //address of DevObj (the first parameter)
a0=809d5550

kd> !drvobj 809d5550 //  display the driver object
Driver object is for:
\Driver\symc810
Device Object list:
809d50d0
```

You can also use **!devobj 809d50d0** to get information about the device object.

[Send comments about this topic to Microsoft](#)

!dskheap

5/31/2017 • 1 min to read • [Edit Online](#)

The **!dskheap** extension displays desktop heap information for a specified session.

```
!dskheap [-v] [-s SessionID]
```

Parameters

-v

Causes the display to include more detailed output.

-s ** SessionID**

Specifies a session. If this parameter is omitted, then the desktop heap information for session 0 is displayed.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about desktops or desktop heaps, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

The desktop heap information for the session is arranged by window station.

Here are a couple of examples:

```
kd> !dskheap -s 3
##  Winstation\Desktop          Heap Size(KB)  Used  Rate(%)

  WinSta0\Screen-saver          3072          0%
  WinSta0\Default                3072          0%
  WinSta0\Disconnect              64          4%
##  WinSta0\Winlogon              128          5%

          Total Desktop: ( 6336 KB - 4 desktops)
#
#           Session ID: 3

kd> !dskheap
##  Winstation\Desktop          Heap Size(KB)  Used  Rate(%)

#           Session ID: 0
```

[Send comments about this topic to Microsoft](#)

!eb, !ed

5/31/2017 • 1 min to read • [Edit Online](#)

The **!eb** and **!ed** extensions write a sequence of values into a specified physical address.

These extension commands should not be confused with the **e* (Enter Values)** command.

```
!eb [Flag] PhysicalAddress Data [ ... ]  
!ed [Flag] PhysicalAddress Data [ ... ]
```

Parameters

Flag

Can be any one of the following values. The *Flag* value must be surrounded by square brackets:

[c]

Writes to cached memory.

[uc]

Writes to uncached memory.

[wc]

Writes to write-combined memory.

PhysicalAddress

Specifies the first physical address on the target computer to which the data will be written, in hexadecimal.

Data

Specifies one or more values to be written sequentially into physical memory. Enter these values in hexadecimal format. For the **!eb** extension, each value must be 1 byte (two hexadecimal digits). For the **!ed** extension, each value must be one DWORD (eight hexadecimal digits). You can include any number of *Data* values on one line. To separate multiple values, use commas or spaces.

DLL

Windows 2000	Kext.dll Kdextx86.dll
Windows XP and later	Kext.dll

Additional Information

To read physical memory, use the **!d*** extensions. For an overview of memory manipulation and a description of other memory-related commands, see [Reading and Writing Memory](#).

[Send comments about this topic to Microsoft](#)

!ecb, !ecd, !ecw

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ecb**, **!ecd**, and **!ecw** extensions write to the PCI configuration space.

```
!ec Bus.Device.Function Offset Data
```

Parameters

Bus

Specifies the bus. *Bus* can range from 0 to 0xFF.

Device

Specifies the slot device number for the device.

Function

Specifies the slot function number for the device.

Offset

Specifies the address at which to write.

Data

Specifies the value to be written. For the **!ecb** extension, *Data* must be 1 byte (two hexadecimal digits). For the **!ecw** extension, *Data* must be one WORD (four hexadecimal digits). For the **!ecd** extension, *Data* must be one DWORD (eight hexadecimal digits).

DLL

Windows 2000	Kext.dll
Windows XP and later	Kext.dll

These extension commands can only be used with an x86-based target computer.

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command, and some additional examples. For information about PCI buses, see the Windows Driver Kit (WDK) documentation.

Remarks

You cannot use these extension commands to write a sequence of *Data* values. This can only be done by repeated use of this extension.

To display the PCI configuration space, use [!pci 100Bus Device Function](#).

[Send comments about this topic to Microsoft](#)

!ecs

5/26/2017 • 1 min to read • [Edit Online](#)

The **!ecs** extension is obsolete. To edit the PCI configuration space, use **!ecb**, **!ecd**, or **!ecw**.

[Send comments about this topic to Microsoft](#)

!errlog

5/31/2017 • 1 min to read • [Edit Online](#)

The **!errlog** extension displays the contents of any pending entries in the I/O system's error log.

```
!errlog
```

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about [IoWriteErrorLogEntry](#), see the Windows Driver Kit (WDK) documentation.

Remarks

This command displays information about any pending events in the I/O system's error log. These are events queued by calls to the [IoWriteErrorLogEntry](#) function, to be written to the system's event log for subsequent viewing by the [Event Viewer](#).

Only entries that were queued by [IoWriteErrorLogEntry](#) but have not been committed to the error log will be displayed.

This command can be used as a diagnostic aid after a system crash because it reveals pending error information that was unable to be committed to the error log before the system halted.

[Send comments about this topic to Microsoft](#)

!errpkt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!errpkt** extension displays the contents of a Windows Hardware Error Architecture (WHEA) hardware error packet.

```
!errpkt Address
```

Parameters

Address

Specifies the address of the hardware error packet.

DLL

Windows 2000	Unavailable
Windows XP	Unavailable
Windows Server 2003	Unavailable
Windows Vista and later	Kdexts.dll

This extension can be used only in Windows Vista and later versions of Windows.

Additional Information

The **!whea** and **!errrec** extensions can be used to display additional WHEA information. For general information about WHEA, see [Windows Hardware Error Architecture \(WHEA\)](#) in the Windows Driver Kit (WDK) documentation.

Remarks

The following example shows the output of the **!errpkt** extension:

```
3: kd> !errpkt ffffffa8007cf44da
WHEA Error Packet Info Section (@ ffffffa8007cf44da)

```

[Send comments about this topic to Microsoft](#)

!errrec

5/31/2017 • 1 min to read • [Edit Online](#)

The **!errrec** extension displays the contents of a Windows Hardware Error Architecture (WHEA) error record.

```
!errrec Address
```

Parameters

Address

Specifies the address of the error record.

DLL

Windows 2000	Unavailable
Windows XP	Unavailable
Windows Server 2003	Unavailable
Windows Vista and later	Kdexts.dll

This extension can be used only in Windows Vista and later versions of Windows.

Additional Information

The **!whea** and **!errpkt** extensions can be used to display additional WHEA information. For general information about WHEA, see [Windows Hardware Error Architecture \(WHEA\)](#) in the Windows Driver Kit (WDK) documentation.

Remarks

The following example shows how the **!whea** extension can be used to obtain the address of an error record, and then the contents of this record can be displayed by the **!errrec** extension:

```
3: kd> !whea

[Send comments about this topic to Microsoft](#)

!exca

5/31/2017 • 1 min to read • [Edit Online](#)

The **!exca** extension displays PC-Card Interrupt Controller (PCIC) Exchangable Card Architecture (ExCA) registers.

```
!exca BasePort.SocketNumber
```

Parameters

BasePort

Specifies the base port of the PCIC.

SocketNumber

Specifies the socket number of the ExCA register on the PCIC.

DLL

Windows 2000	Kext.dll Kdextx86.dll
Windows XP and later	Kext.dll

The **!exca** extension is only available for an x86-based target computer.

Additional Information

The **!cbreg** extension can be used to display CardBus Socket registers and CardBus ExCA registers by address.

[Send comments about this topic to Microsoft](#)

!filecache

5/31/2017 • 3 min to read • [Edit Online](#)

The **!filecache** extension displays information regarding the system file cache memory and PTE use.

```
!filecache [Flags]
```

Parameters

Flags

Optional. Default value is 0x0. Set *Flags* to 0x1 to sort the output by shared cache map. This way you can locate all the system cache views for a given control area.

DLL

Kdexts.dll

Additional Information

For information about file system drivers, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

Each line of this extension's output represents a virtual address control block (VACB). When named files are mapped into the VACB, the names of these files are displayed. If "no name for file" is specified, this means that this VACB is being used to cache metadata.

Here is an example of the output from this extension from a Windows XP system:

```
kd> !filecache
***** Dump file cache*****
Reading and sorting VACBs ...
Removed 1811 nonactive VACBs, processing 235 active VACBs ...
File Cache Information
  Current size 28256 kb
  Peak size    30624 kb
  235 Control Areas
Skipping view @ c1040000 - no VACB, but PTE is valid!
  Loading file cache database (100% of 131072 PTEs)
  SkippedPageTableReads = 44
  File cache has 4056 valid pages
```

```
Usage Summary (in Kb):
Control Valid Standby/Dirty Shared Locked Name
817da668    4      0      0      0  $MftMirr
8177ae68   304     920     0      0  $LogFile
81776160   188      0      0      0  $BitMap

!filelock

5/31/2017 • 1 min to read • [Edit Online](#)

The **!filelock** extension displays a file lock structure.

Syntax

```
!filelock FileLockAddress
!filelock ObjectAddress
```

Parameters

FileLockAddress

Specifies the hexadecimal address of the file lock structure.

ObjectAddress

Specifies the hexadecimal address of a file object that owns the file lock.

DLL

Kdexts.dll

Additional Information

For information about file objects, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

[Send comments about this topic to Microsoft](#)

!fileobj

5/31/2017 • 1 min to read • [Edit Online](#)

The **!fileobj** extension displays detailed information about a FILE_OBJECT structure.

```
!fileobj FileObject
```

Parameters

FileObject

Specifies the address of a FILE_OBJECT structure.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about file objects, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

If the FILE_OBJECT structure has an associated cache, **!fileobj** tries to parse and display cache information..

[Send comments about this topic to Microsoft](#)

!filetime

5/31/2017 • 1 min to read • [Edit Online](#)

The **!filetime** extension converts a 64-bit FILETIME structure into a human-readable time.

```
!filetime Time
```

Parameters

Time

Specifies a 64-bit FILETIME structure.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

Here is an example of the output from this extension:

```
kd> !filetime 1c4730984712348
7/26/2004 04:10:18.712 (Pacific Standard Time)
```

[Send comments about this topic to Microsoft](#)

!finddata

5/31/2017 • 1 min to read • [Edit Online](#)

The **!finddata** extension displays the cached data at a given offset within a specified file object.

```
!finddata FileObject Offset
```

Parameters

FileObject

Specifies the address of the file object.

Offset

Specifies the offset.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about cache management, see the Microsoft Windows SDK documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

For information about other cache management extensions, see the [!cchelp](#) extension.

[Send comments about this topic to Microsoft](#)

!findfilelockowner

5/31/2017 • 1 min to read • [Edit Online](#)

The **!findfilelockowner** extension attempts to find the owner of a file object lock by examining all threads for a thread that is blocked in an **!opSynchronousServiceTail** assert and that has the file object as a parameter.

```
!findfilelockowner [FileObject]
```

Parameters

FileObject

Specifies the address of a file object. If *FileObject* is omitted, the extension searches for any thread in the current process that is stuck in **!opAcquireFileObjectLock** and retrieves the file object address from the stack trace.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about file objects, see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

Remarks

This extension is most useful after a critical section timeout in which the thread that times out was waiting for the file inside **!opAcquireFileObjectLock**. After the offending thread is found, the extension attempts to recover the IRP that was used for the request and to display the driver that was processing the IRP.

The extension takes some time to complete because it walks the stack of all threads in the system until it finds the offending thread. You can stop ` at any point by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!findthreads

5/31/2017 • 2 min to read • [Edit Online](#)

The !findthreads extension displays summary information about one or more threads on the target system based on supplied search criteria. Thread information will be displayed when the associated stack(s) reference the supplied object. This command can be used only during kernel-mode debugging.

Syntax

```
!findthreads [-v][-t <Thread Address>|-i <IRP Address>|-d <Device Address>|(-a <Pointer Address> -e <End Address> | -l <Range Length>)]
```

Parameters

-v

Displays verbose information on all criteria matches.

-t ** Thread Address**

The search criteria will be all modules, wait objects, and IRPs for the thread, as well as device objects and modules generated from the attached IRPs. This option will generally provide the broadest search criteria.

-i ** IRP Address**

The search criteria will be all modules and devices for the indicated IRP, as well as any reference to the IRP itself.

-d ** Device Address**

The search criteria will be based from the device object. This will include the module associated with the device object (through the driver object), the device extension, any IRP attached to the device, and similar information for any attached to the device object.

-a ** Pointer Address**

Add a base address to the criteria. If -e or -l is correctly specified, this value will be the base of a memory range. Otherwise it is interpreted as a pointer.

-e ** End Address**

Specifies the end address of the memory range specified with -a.

-l ** Range Length**

Specifies the length of the memory range specified with -a.

DLL

Windows 10 and later	Kdexts.dll
-----------------------------	------------

Additional Information

For information about threads in kernel mode, see [Changing Contexts](#). For more information about analyzing processes and threads, see *Microsoft Windows Internals*, by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

Here is example output using the -v and -t options:

```
kd> !findthreads -v -t fffffd001ee29cdc0

Added criterion for THREAD 0xfffffd001ee29cdc0
Added criterion for THREAD STACK 0xfffffd001ee2bac20
ERROR: Object 0xfffffffffffffe0 is not an IRP
ERROR: unable to completely walk thread IRP list.

[Send comments about this topic to Microsoft](#)

!for_each_process

5/31/2017 • 1 min to read • [Edit Online](#)

The **!for_each_process** extension executes the specified debugger command once for each process in the target.

```
!for_each_process ["CommandString"]
!for_each_process -?
```

Parameters

CommandString

Specifies the debugger commands to be executed for each process.

If *CommandString* includes multiple commands, separate them with semicolons (;) and enclose *CommandString* in quotation marks (""). If *CommandString* is enclosed in quotations marks, the individual commands within *CommandString* cannot contain quotation marks. Within *CommandString*, **@#Process** is replaced by the process address.

-?

Displays help for this extension in the Debugger Command window.

DLL

This extension works only in kernel mode, even though it resides in Ext.dll.

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For general information about processes, see [Threads and Processes](#). For information about manipulating or obtaining information about processes, see [Controlling Processes and Threads](#).

Remarks

If no arguments are supplied, the debugger displays a list of all processes, along with time and priority statistics. This is equivalent to entering **!process @#Process 0** as the *CommandString* value.

To terminate execution at any point, press CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!for_each_thread

5/31/2017 • 1 min to read • [Edit Online](#)

The **!for_each_thread** extension executes the specified debugger command once for each thread in the target.

```
!for_each_thread ["CommandString"]
!for_each_thread -?
```

Parameters

CommandString

Specifies the debugger commands to be executed for each thread. If *CommandString* includes multiple commands, separate them with semicolons (;) and enclose *CommandString* in quotation marks (""). If *CommandString* is enclosed in quotations marks, the individual commands within *CommandString* cannot contain quotation marks. Within *CommandString*, **@#Thread** is replaced by the thread address.

-?

Displays help for this extension in the Debugger Command window.

DLL

This extension works only in kernel mode, even though it resides in Ext.dll.

Windows 2000	Ext.dll
Windows XP and later	Ext.dll

Additional Information

For more general information about threads, see [Threads and Processes](#). For more information about manipulating or obtaining information about threads, see [Controlling Processes and Threads](#).

Remarks

If no arguments are supplied, the debugger displays a list of all threads, along with thread wait states. This is equivalent to entering **!thread @#Thread 2** as the *CommandString* value.

You can terminate execution at any point by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!fpsearch

5/31/2017 • 1 min to read • [Edit Online](#)

The **!fpsearch** extension searches the freed special pool for a specified address.

```
!fpsearch [Address] [Flag]
```

Parameters

Address

Specifies a virtual address.

Flag

If set, the debugger displays the raw content of each page on the free list as it searches the freed special pool.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Remarks

The display for an address includes the virtual address, the page frame number (PFN), the pool tag, size, whether the data at the address is pageable, the thread ID, and the call stack at the time of deallocation.

If *Address* is set to -1, the debugger displays the entire freed special pool.

If the debugger cannot find the specified address in the freed special pool, it does not display anything. Here is an example of the output from this extension:

```
kd> !fpsearch -1 1
Searching the free page list (8 entries) for all freed special pool

!fxdevice

5/31/2017 • 1 min to read • [Edit Online](#)

The !fxdevice extension displays summary information about all Power Management Framework (PoFx) registered devices. This command can be used only during kernel-mode debugging.

For more information about PoFx, see [Overview of the Power Management Framework](#).

Syntax

```
!fxdevice[<FxDevice Address>]
```

Parameters

< FxDevice Address >

Provides the address of the FxDevice to display.

DLL

Windows 10 and later	Kdexts.dll
-----------------------------	------------

Remarks

The !fxdevice extension displays the following information when it is present on the target system.

- Non-idle PoFx devices
- Idle D0 PoFx devices
- Idle non-D0 PoFx devices

The following is example out from the !fxdevice extension with a supplied device address.

```
kd> !fxdevice fffffe0012ccbda60

!gbl

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gbl** extension displays header information from the ACPI BIOS Root System Description (RSDT) table of the target computer.

```
!gbl [-v]
```

Parameters

-v

Verbose. Displays detailed information about the table.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about the ACPI and ACPI tables, see [Other ACPI Debugging Extensions](#) and the [ACPI Specification](#) Web site. Also see the Microsoft Windows SDK documentation, the Windows Driver Kit (WDK) documentation, and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

[Send comments about this topic to Microsoft](#)

!gentable

5/31/2017 • 1 min to read • [Edit Online](#)

The **!gentable** extension displays an RTL_GENERIC_TABLE.

Syntax

```
!gentable Address[Flag]
```

Parameters

Address

Specifies the address of the RTL_GENERIC_TABLE.

Flag

Specifies the table source. If *Flag* is 1, the AVL table is used. If *Flag* is 0 or omitted, the non-AVL table is used.

DLL

Kdexts.dll

[Send comments about this topic to Microsoft](#)

!hidppd

5/31/2017 • 1 min to read • [Edit Online](#)

The **!hidppd** extension displays the contents of the HIDP_PREPARSED_DATA structure.

```
!hidppd Address
```

Parameters

Address

Specifies the hexadecimal address of the HIDP_PREPARSED_DATA structure.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

For information about human input devices (HID), see the Windows Driver Kit (WDK) documentation.

[Send comments about this topic to Microsoft](#)

!ib, !id, !iw

5/26/2017 • 1 min to read • [Edit Online](#)

The **!ib**, **!id**, and **!iw** extension commands are obsolete. Use the **ib**, **id**, **iw (Input from Port)** commands instead.

[Send comments about this topic to Microsoft](#)

!icpleak

5/31/2017 • 1 min to read • [Edit Online](#)

The **!icpleak** extension examines all I/O completion objects in the system for the object with the largest number of queued entries.

```
!icpleak [HandleFlag]
```

Parameters

HandleFlag

If this flag is set, the display also includes all processes that have a handle to the object with the largest number of queued entries.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Additional Information

For information about I/O completion ports, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (This book may not be available in some languages and countries.)

Remarks

This extension is useful when there is a leak in the I/O completion pool. I/O completion pool leaks can occur when a process is allocating I/O completion packets by calling **PostQueuedCompletionStatus**, but is not calling **GetQueuedCompletionStatus** to free them, or when a process is queuing completion entries to a port, but there is no thread retrieving the entries. To detect a leak run the **!poolused** extension and check the value of ICP pool tag. If pool use with the ICP tag is significant, a leak might have occurred.

This extension works only if the system maintains type lists. If the *HandleFlag* is set and the system has many processes, this extension will take a long time to run.

You can stop at any point by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

[Send comments about this topic to Microsoft](#)

!idt

5/31/2017 • 1 min to read • [Edit Online](#)

The **!idt** extension displays the interrupt service routines (ISRs) for a specified interrupt dispatch table (IDT).

```
!idt IDT
!idt [-a]
!idt -?
```

Parameters

IDT

Specifies the IDT to display.

-a

When *IDT* is not specified, the debugger displays the IDTs of all processors on the target computer in an abbreviated format. If **-a** is specified, the ISRs for each IDT are also displayed.

-?

Displays help for this extension in the Debugger Command window.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an x64-based or x86-based target computer.

Additional Information

For information about ISRs and IDTs, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. (These resources may not be available in some languages and countries.)

For more information about how to display the interrupt vector tables on an Itanium target computer, see [!ivt](#).

Remarks

Here is an example of the output from this extension:

[Send comments about this topic to Microsoft](#)

!ih

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ih** extension displays the interrupt history record for the specified processor.

`!ih Processor`

Important This command has been deprecated in the Windows Debugger Version 10.0.14257 and later, and is no longer available.

Parameters

Processor

Specifies a processor. If *Processor* is omitted, the current processor is used.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an Itanium-based target computer.

Remarks

This extension displays the interrupt history record without referencing the program counter symbols. To display the interrupt history record using the program counter symbols, use the **!ihs** extension. To enable the interrupt history record, add **/configflag=32** to the boot entry options.

Here is an example of the output from this extension:

```

kd> !ih

!ioresdes

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ioresdes** extension displays the IO_RESOURCE_DESCRIPTOR structure at the specified address.

```
!ioresdes Address
```

Parameters

Address

Specifies the hexadecimal address of the IO_RESOURCE_DESCRIPTOR structure.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about the IO_RESOURCE_DESCRIPTOR structure, see the Windows Driver Kit (WDK) documentation.

[Send comments about this topic to Microsoft](#)

!ioctldecode

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ioctldecode** extension displays the *Device Type*, *Required Access*, *Function Code* and *Transfer Type* as specified by the given IOCTL code. For more information about IOCTL control codes, see [Defining I/O Control Codes](#).

```
!ioctldecode IoctlCode
```

Parameters

IoctlCode

Specifies the hexadecimal IOCTL Code. The [!irp](#) command displays the IOCTL code in its output.

DLL

Kdexts.dll

Additional Information

To see information on the IOCTL, we first locate an IRP of interest. You can use the [!irpfind](#) command to locate an irp of interest.

Use the [!irp](#) command to display information about the irp.

```
0: kd> !irp fffffd581a6c6cd30

    \Driver\usbhci          (IopUnloadSafeCompletion)
                                                Args: fffffd581a6c61a50 00000000 0x220003 00000000
```

The third argument displayed, in this case *0x220003*, is the IOCTL code. Use the IOCTL code to display information

about the IOCTL, in this case **IOCTL_INTERNAL_USB_SUBMIT_URB**.

```
0: kd> !ioctldecode 0x220003

IOCTL_INTERNAL_USB_SUBMIT_URB

Device Type      : 0x22 (FILE_DEVICE_WINLOAD) (FILE_DEVICE_USER_MODE_BUS) (FILE_DEVICE_USB)
(FILE_DEVICE_UNKNOWN)
Method          : 0x3 METHOD_NEITHER
Access          : FILE_ANY_ACCESS
Function        : 0x0
```

If you provide an IOCTL code that is not available, you will see this type of output.

```
0: kd> !ioctldecode 0x1280ce

Unknown IOCTL  : 0x1280ce

Device Type      : 0x12 (FILE_DEVICE_NETWORK)
Method          : 0x2 METHOD_OUT_DIRECT
Access          : FILE_WRITE_ACCESS
Function        : 0x33
```

Although the IOCTL is not identified, information about the IOCTL fields are displayed.

Note that only a subset of publically defined IOCTLs are able to be identified by the **!ioctldecode** command.

For more information about IOCTLs see [Introduction to I/O Control Codes](#).

For more general information about IRPs and IOCTLs, refer to *Windows Internals* by Mark E. Russinovich, David A. Solomon and Alex Ionescu.

!ioreslist

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ioreslist** extension displays an IO_RESOURCE_REQUIREMENTS_LIST structure.

```
!ioreslist Address
```

Parameters

Address

Specifies the hexadecimal address of the IO_RESOURCE_REQUIREMENTS_LIST structure.

DLL

Windows 2000	Kdextx86.dll
Windows XP and later	Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) for applications of this extension command. For information about the IO_RESOURCE_REQUIREMENTS_LIST structure, see the Windows Driver Kit (WDK) documentation.

Remarks

Here is an example of the output from this extension:

```

kd> !ioreslist 0xe122b768

IoResList at 0xe122b768 : Interface 0x5 Bus 0 Slot 0xe
Alternative 0 (Version 1.1)
Preferred Descriptor 0 - Port (0x1) Device Exclusive (0x1)
Flags (0x01) - PORT_IO
0x000100 byte range with alignment 0x000100
1000 - 0x10ff
Alternative Descriptor 1 - Port (0x1) Device Exclusive (0x1)
Flags (0x01) - PORT_IO
0x000100 byte range with alignment 0x000100
0 - 0xffffffff
Descriptor 2 - DevicePrivate (0x81) Device Exclusive (0x1)
Flags (0000) -
Data: : 0x1 0x0 0x0
Preferred Descriptor 3 - Memory (0x3) Device Exclusive (0x1)
Flags (0000) - READ_WRITE
0x001000 byte range with alignment 0x001000
40080000 - 0x40080fff
Alternative Descriptor 4 - Memory (0x3) Device Exclusive (0x1)
Flags (0000) - READ_WRITE
0x001000 byte range with alignment 0x001000
0 - 0xffffffff
Descriptor 5 - DevicePrivate (0x81) Device Exclusive (0x1)
Flags (0000) -
Data: : 0x1 0x1 0x0
Descriptor 6 - Interrupt (0x2) Shared (0x3)
Flags (0000) - LEVEL_SENSITIVE
0xb - 0xb

```

The IO_RESOURCE_REQUIREMENTS_LIST contains information about:

- Resource types

There are four types of resources: I/O, Memory, IRQ, DMA.

- Descriptors

Each preferred setting has a "Preferred" descriptor and a number of "Alternative" descriptors.

This resource list contains the following requests:

- I/O Ranges

Prefers a range of 0x1000 to 0x10FF inclusive, but can use any 0x100 range between 0 and 0xFFFFFFFF, provided it is 0x100-aligned. (For example, 0x1100 to 0x11FF is acceptable.)

- Memory

Prefers a range of 0x40080000 to 0x40080FFF, but can use any range that is of size 0x1000, is 0x1000-aligned, and is located between 0 and 0xFFFFFFFF.

- IRQ

Must use IRQ 0xB.

Interrupts and DMA channels are represented as ranges with the same beginning and end.

!iovirp

5/31/2017 • 1 min to read • [Edit Online](#)

The **!iovirp** extension displays detailed information for a specified I/O Verifier IRP.

```
!iovirp [IRP]
```

Parameters

IRP

Specifies the address of an IRP tracked by the Driver Verifier. If *IRP* is 0 or is omitted, the summary information for each outstanding IRP is displayed.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

Remarks

Here is an example of the output from this extension:

```
kd> !iovirp 947cef68
IovPacket      84509af0
TrackedIrp    947cef68
HeaderLock     84509d61
LockIrql       0
ReferenceCount 1
PointerCount   1
HeaderFlags    00000000
ChainHead      84509af0
Flags          00200009
DepartureIrql 0
ArrivalIrql   0
StackCount     1
QuotaCharge   00000000
QuotaProcess  0
RealIrpCompletionRoutine 0
RealIrpControl 0
RealIrpContext 0
TopStackLocation 2
PriorityBoost   0
LastLocation    0
RefTrackingCount 0
SystemDestVA   0
VerifierSettings 84509d08
pIovSessionData 84509380
Allocation Stack:
  nt!IovAllocateIrp+1a  (817df356)
  nt!IopXxxControlFile+40c  (8162de20)
  nt!NtDeviceIoControlFile+2a  (81633090)
  nt!KiFastCallEntry+164  (81513c64)
  nt!EtwpFlushBuffer+10f  (817606d7)
  nt!EtwpFlushBuffersWithMarker+bd  (817608cb)
  nt!EtwpFlushActiveBuffers+2b4  (81760bc2)
  nt!EtwpLogger+213  (8176036f)
```

You can stop execution at any point by pressing CTRL+BREAK (in WinDbg) or CTRL+C (in KD).

!ipi

5/31/2017 • 1 min to read • [Edit Online](#)

The **!ipi** extension displays the interprocessor interrupt (IPI) state for a specified processor.

```
!ipi [Processor]
```

Parameters

Processor

Specifies a processor. If *Processor* is omitted, the IPI state for every processor is displayed.

DLL

Windows 2000	Unavailable
Windows XP and later	Kdexts.dll

This extension command can only be used with an x86-based target computer.

Additional Information

For information about IPIs, see *Microsoft Windows Internals* by Mark Russinovich and David Solomon.

Remarks

Here is an example of the output from this extension:

```
0: kd> !ipi
IPI State for Processor 0
  Worker Routine: nt!KiFlushTargetMultipleTb [Stale]
  Parameter[0]: 0
  Parameter[1]: 3
  Parameter[2]: F7C98770
  Ipi Trap Frame: F7CCCCDC [.trap F7CCCCDC]
  Signal Done: 0
  IPI Frozen: 24 [FreezeActive] [Owner]
  Request Summary: 0
  Target Set: 0
  Packet Barrier: 0

IPI State for Processor 1
  Worker Routine: nt!KiFlushTargetMultipleTb [Stale]
  Parameter[0]: 1
  Parameter[1]: 3
  Parameter[2]: F7CDCD28
  Ipi Trap Frame: F7C8CCC4 [.trap F7C8CCC4]
  Signal Done: 0
  IPI Frozen: 2 [Frozen]
  Request Summary: 0
  Target Set: 0
  Packet Barrier: 0
```

title: irp extension command description: The irp extension displays information about an I/O request packet (IRP).
ms.assetid: 2260255d-813b-4b89-8dbe-6ce7e5596ccf keywords: ["IRP", "IRP, See \"I/O Request Packet (IRP)\"", "irp Windows Debugging"] ms.author: windowsdriverdev ms.date: 05/23/2017 ms.topic: article ms.prod: windows-hardware ms.technology: windows-devices topic_type:

- apiref api_name:
- irp api_type:

- NA

!irp

The **!irp** extension displays information about an I/O request packet (IRP).

!irp Address [Detail]

Parameters

Address

Specifies the hexadecimal address of the IRP.

Detail

If this parameter is included with any value, such as 1, the output includes the status of the IRP, the address of its memory descriptor list (MDL), its owning thread, and stack information for all of its I/O stacks, and information about each stack location for the IRP, including hexadecimal versions of the major function code and the minor function code. If this parameter omitted, the output includes only a summary of the information.

DLL

Windows XP and later

Kdexts.dll

Additional Information

See [Plug and Play Debugging](#) and [Debugging Interrupt Storms](#) for applications of this extension command. For information about IRPs, see the Windows Driver Kit (WDK) documentation and *Microsoft Windows Internals* by Mark Russinovich and David Solomon. For further information on the major and minor function codes, see the Windows Driver Kit (WDK) documentation. (These resources may not be available in some languages and countries.)

This MSDN topic describes the IRP structure, [IRP](#).

Remarks

The output also indicates under what conditions the completion routine for each stack location will be called once the IRP has completed and the stack location is processed. There are three possibilities:

Success

Indicates that the completion routine will be called when the IRP is completed with a success code.

Error

Indicates that the completion routine will be called when the IRP is completed with an error code.

Cancel

Indicates that the completion routine will be called if an attempt was made to cancel the IRP.

Any combination of these three may appear, and if any of the conditions shown are satisfied, the completion routine will be called. The appropriate values are listed at the end of the first row of information about each stack location, immediately after the **Completion-Context** entry.

Here is an example of the output from this extension for Windows 10:

```
0: kd> !irp ac598dc8
Irp is active with 2 stacks 1 is current (= 0xac598e38)
No Mdl: No System Buffer: Thread 8d1c7bc0: Irp stack trace.
    cmd  flg cl Device   File   Completion-Context
>[IRP_MJ_FILE_SYSTEM_CONTROL(d), N/A(0)]
    1 e1 8a6434d8 ac598d40 853220cb-a89682d8 Success Error Cancel pending
    \FileSystem\Npfs fltmgr!FltpPassThroughCompletion
    Args: 00000000 00000000 00110008 00000000
[IRP_MJ_FILE_SYSTEM_CONTROL(d), N/A(0)]
    1 0 8a799710 ac598d40 00000000-00000000
    \FileSystem\FltMgr
    Args: 00000000 00000000 0x00110008 00000000
```

Starting with Windows 10 the IRP major and minor code text is displayed, for example, "IRP_MJ_FILE_SYSTEM_CONTROL" The code value is also shown in hex, in this example "(d)".

The third argument displayed in the output, is the IOCTL code. Use the [!ioctldecode](#) command to display information about the IOCTL.

Here is an example of the output from this extension from Windows Vista.

```

0: kd> !irp 0x831f4a00
Irp is active with 8 stacks 5 is current (= 0x831f4b00)
Mdl = 82b020d8 Thread 8c622118: Irp stack trace.
